## Introduction to CLC Genomics Workbench

Welcome to CLC Genomics Workbench 12.0 — a software package supporting your daily bioinformatics work.

We strongly encourage you to read this user manual in order to get the best possible basis for working with the software package.

This software is for research purposes only.

---

CHAPTER 1. INTRODUCTION TO CLC GENOMICS WORKBENCH

1.1 Contact information

The CLC Genomics Workbench is developed by:

QIAGEN Aarhus
Silkeborgvej 2
Prismet
8000 Aarhus C
Denmark

http://www.qiagenbioinformatics.com
Email: ts-bioinformatics@qiagen.com

The QIAGEN Aarhus team is continuously improving CLC Genomics Workbench with our users’ interests in mind. We welcome all requests and feedback from users, as well as suggestions for new features or more general improvements to the program.

Getting help via the workbench  If you encounter a problem or need help understanding how CLC Genomics Workbench works, and the license you are using is covered by our Maintenance, Upgrades and Support (MUS) program (http://www.qiagenbioinformatics.com/maintenance-and-support/), you can contact our customer support via the workbench by going to the menu option:

Help | Contact Support

This will open a dialog where you can enter your contact information, and a text field for writing the question or problem you have. On a second dialog you will be given the chance to attach screenshots or even small datasets that can help explain or troubleshoot the problem. When you send a support request this way, it will automatically include helpful technical information about your installation and your license information so that you do not have to look this up yourself. Our support staff will reply to you by email.

Other ways to contact the support team  You can also contact the support team by email: ts-bioinformatics@qiagen.com

Please provide your contact information, your license information, some technical information about your installation, and describe the question or problem you have. You can also attach screenshots or even small data sets that can help explain or troubleshoot the problem.

Information about how to to find your license information is included in the licenses section of our Frequently Asked Questions (FAQ) area: https://secure.clcbio.com/helpspot/index.php?pg=kb. Information about MUS cover on particular licenses can be found by https://secure.clcbio.com/myclc/login.
1.2 Download and installation

The CLC Genomics Workbench is developed for Windows, macOS and Linux. The software for either platform can be downloaded from http://www.qiagenbioinformatics.com/product-downloads/. To check for available updates of the workbench and plugins, click on Help | Check for Updates... ( OSError )

1.2.1 Program download

Before you download the program you are asked to fill in the Download dialog. In the dialog you must choose:

- Which operating system you use
- Whether you would like to receive information about future releases

When the download of the installer (an application which facilitates the installation of the program) is complete, follow the platform specific instructions below to complete the installation procedure.

1.2.2 Installation on Microsoft Windows

When you have downloaded an installer, locate the downloaded installer and double-click the icon. The default location for downloaded files is your desktop.

Installing the program is done in the following steps:

- On the welcome screen, click Next.
- Read and accept the License agreement and click Next.
- Choose where you would like to install the application and click Next.
- Choose a name for the Start Menu folder used to launch CLC Genomics Workbench and click Next.
- Choose if CLC Genomics Workbench should be used to open CLC files and click Next.
- Choose where you would like to create shortcuts for launching CLC Genomics Workbench and click Next.
- Choose if you would like to associate .clc files to CLC Genomics Workbench. If you check this option, double-clicking a file with a "clc" extension will open the CLC Genomics Workbench.
- Wait for the installation process to complete, choose whether you would like to launch CLC Genomics Workbench right away, and click Finish.

When the installation is complete the program can be launched from the Start Menu or from one of the shortcuts you chose to create.
1.2.3 Installation on macOS

Starting the installation process is done in the following way: When you have downloaded an installer, locate the downloaded installer and double-click the icon. The default location for downloaded files is your desktop.

Launch the installer by double-clicking on the "CLC Genomics Workbench" icon.

Installing the program is done in the following steps:

- On the welcome screen, click Next.
- Read and accept the License agreement and click Next.
- Choose where you would like to install the application and click Next.
- Choose if CLC Genomics Workbench should be used to open CLC files and click Next.
- Choose whether you would like to create desktop icon for launching CLC Genomics Workbench and click Next.
- Wait for the installation process to complete, choose whether you would like to launch CLC Genomics Workbench right away, and click Finish.

When the installation is complete the program can be launched from your Applications folder, or from the desktop shortcut you chose to create. If you like, you can drag the application icon to the dock for easy access.

1.2.4 Installation on Linux with an installer

Navigate to the directory containing the installer and execute it. This can be done by running a command similar to:

```
# sh CLCGenomicsWorkbench_12_0_64.sh
```

Installing the program is done in the following steps:

- On the welcome screen, click Next.
- Read and accept the License agreement and click Next.
- Choose where you would like to install the application and click Next.
  *For a system-wide installation you can choose for example /opt or /usr/local. If you do not have root privileges you can choose to install in your home directory.*
- Choose where you would like to create symbolic links to the program
  *DO NOT create symbolic links in the same location as the application.*
  Symbolic links should be installed in a location which is included in your environment PATH. For a system-wide installation you can choose for example /usr/local/bin. If you do not have root privileges you can create a ‘bin’ directory in your home directory and install symbolic links there. You can also choose not to create symbolic links.
• Wait for the installation process to complete and click **Finish**.

If you choose to create symbolic links in a location which is included in your PATH, the program can be executed by running the command:

```bash
# clcgenomicswb12
```

Otherwise you start the application by navigating to the location where you choose to install it and running the command:

```bash
# ./clcgenomicswb12
```

### 1.3 System requirements

- OS X 10.10, 10.11 and macOS 10.12, 10.13, 10.14
- Linux: RHEL 7 and later, SUSE Linux Enterprise Server 11 and later. The software is expected to run without problem on other recent Linux systems, but we do not guarantee this.
- 64 bit operating system
- 2 GB RAM required
- 4 GB RAM recommended
- 1024 x 768 display required
- 1600 x 1200 display recommended
- Intel or AMD CPU required

**Special system requirements for the 3D Molecule Viewer**

- **Requirements**
  - A graphics card capable of supporting OpenGL 2.0.
  - Updated graphics drivers. Please make sure the latest driver for the graphics card is installed.

- **Recommendations**
  - A discrete graphics card from either Nvidia or AMD/ATI. Modern integrated graphics cards (such as the Intel HD Graphics series) may also be used, but these are usually slower than the discrete cards.

  Indirect rendering (such as x11 forwarding through ssh), remote desktop connection/VNC, and running in virtual machines is not supported.
CHAPTER 1. INTRODUCTION TO CLC GENOMICS WORKBENCH

Special system requirements for read mapping. The numbers below give minimum and recommended memory for systems running mapping and analysis tasks. The requirements suggested are based on the genome size.

- **E. coli K12 (4.6 megabases)**
  - Minimum: 2 GB RAM
  - Recommended: 4 GB RAM

- **C. elegans (100 megabases) and Arabidopsis thaliana (120 megabases)**
  - Minimum: 2 GB RAM
  - Recommended: 4 GB RAM

- **Zebrafish (1.5 gigabases)**
  - Minimum: 2 GB RAM
  - Recommended: 4 GB RAM

- **Human (3.2 gigabases) and Mouse (2.7 gigabases)**
  - Minimum: 6 GB RAM
  - Recommended: 8 GB RAM

Special requirements for de novo assembly. De novo assembly may need more memory than stated above - this depends both on the number of reads, error profile and the complexity and size of the genome. See [http://resources.qiagenbioinformatics.com/white-papers/White_paper_on_de_novo_assembly_4.pdf](http://resources.qiagenbioinformatics.com/white-papers/White_paper_on_de_novo_assembly_4.pdf) for examples of the memory usage of various data sets.

### 1.3.1 Limitations on maximum number of cores

Most modern CPUs implements hyper threading or a similar technology which makes each physical CPU core appear as two logical cores on a system. In this manual the term "core" always refer to a logical core unless otherwise stated.

For static licenses, there is a limitation on the number of logical cores on the computer. If there are more than 64 logical cores, the CLC Genomics Workbench cannot be started. In this case, a network license is needed (read more at [http://www.qiagenbioinformatics.com/support/licensing/](http://www.qiagenbioinformatics.com/support/licensing/)).

### 1.4 Workbench Licenses

When you start up the CLC Genomics Workbench for the first time on your system, or after installing a new major release, the **License Assistant**, shown in figure 1.1, will be presented to you. The **License Assistant** can be also be launched during an active Workbench session by clicking on the "Upgrade Workbench License" button at the bottom of the **License Manager**. The **License Manager** can be started up using the Workbench menu item:

Help | License Manager
Figure 1.1: The License Assistant provides access to licensing options.

The options available in the License Assistant window are described in brief below, and then in detail in the sections that follow.

- **Request an evaluation license** Request a fully functional, time-limited license.
- **Download a license** Use the license order ID provided when you purchase the software to download and install a license file.
- **Import a license from a file** Import an existing license file, for example a file downloaded from the license download webpage.
- **Upgrade from an existing Workbench installation** If you have used a previous version of the CLC Genomics Workbench, and you are entitled to upgrade to a new major version, select this option to upgrade your license file.
- **Configure License Server connection** If your organization has a CLC License Server, select this option to configure the connection to it.

Select the appropriate option and then click on the Next button.

To use the Request an evaluation license, Download a license or the Upgrade from an existing Workbench installation options, your machine must be able to access the external network. If this is not the case, please see section 1.4.6.

When using a CLC Genomics Workbench installed in a central location on your system, you must be running the program in administrative mode to license the software. On Linux and Mac, this means you must be logged in as an administrator. On Windows, you can right-click the program shortcut and choose “Run as Administrator”.

If you do not have a license order ID or access to a license, you can still use the Workbench in Viewing Mode. See section 1.4.7 for further information about this.

### 1.4.1 Request an evaluation license

We offer a fully functional version of the CLC Genomics Workbench for evaluation purposes, free of charge. Each person is entitled to a 14-day trial of CLC Genomics Workbench. If
you are unable to complete your assessment in the available time, please send an email to bioinformaticssales@qiagen.com to request an additional evaluation period.

When you choose the option **Request an evaluation license**, you will see the dialog shown in figure 1.2.

![Request an evaluation license](image1)

Figure 1.2: Choose between downloading a license directly, or opening the license download form in a web browser.

In this dialog, there are two options:

- **Direct Download.** Download the license directly. This method requires that the Workbench has access to the external network.

- **Go to CLC License Download web page.** The online license download form will be opened in a web browser. This option is suitable for when downloading a license for use on another machine that does not have access to the external network, and thus cannot access the QIAGEN Aarhus servers.

After selecting your method of choice, click on the button labeled **Next**.

**Direct download**

After choosing the **Direct Download** option and clicking on the button labeled **Next**, a dialog similar to that shown in figure 1.3 will appear if the license is successfully downloaded and installed.

![Requesting a license](image2)

Figure 1.3: A license has been successfully downloaded and installed for use.

When the license has been downloaded and installed, the **Next** button will be enabled. If there is a problem, a dialog will appear indicating this.
Go to license download web page

After choosing the Go to CLC License Download web page option and clicking on the button labeled Next, the license download form will be opened in a web browser, as shown in figure 1.4.

![License download form](image)

Figure 1.4: The license download form opened in a web browser.

Click on the Download License button and then save the license file.

Back in the Workbench window, you will now see the dialog shown in 1.5.

![License import dialog](image)

Figure 1.5: Importing the license file downloaded from the web page.

Click on the Choose License File button, find the saved license file and select it. Then click on the Next button.

Accepting the license agreement

The end user license agreement (EULA) must be read and accepted as part of the installation process. figure 1.28.

Please read the EULA text carefully, and if you agree to it, check the box next to the text I accept these terms. If further information is requested from you, please fill this in before clicking on the Finish button.

1.4.2 Download a license using a license order ID

Using a license order ID, you can download a license file via the Workbench or using an online form. When you have chosen this option and clicked on the Next button, you will see the dialog shown in 1.7. Enter your license order ID into the License Order ID text field. (The ID can be pasted into the box after copying it and then right clicking in the text field and choosing Paste from the context menu, or using a key combination like Ctrl+V, or on a Mac, ⌘+V).
CHAPTER 1. INTRODUCTION TO CLC GENOMICS WORKBENCH

Figure 1.6: The End User License Agreement is presented during the installation process.

In this dialog, there are two options:

- **Direct Download**. Download the license directly. This method requires that the Workbench has access to the external network.

- **Go to CLC License Download web page**. The online license download form will be opened in a web browser. This option is suitable for when downloading a license for use on another machine that does not have access to the external network, and thus cannot access the QIAGEN Aarhus servers.

After selecting your method of choice, click on the button labeled **Next**.

**Direct download**

After choosing the **Direct Download** option and clicking on the button labeled **Next**, a dialog similar to that shown in figure 1.8 will appear if the license is successfully downloaded and installed.
CHAPTER 1. INTRODUCTION TO CLC GENOMICS WORKBENCH

Figure 1.8: A license has been successfully downloaded and installed for use.

When the license has been downloaded and installed, the Next button will be enabled. If there is a problem, a dialog will appear indicating this.

Go to license download web page

After choosing the Go to CLC License Download web page option and clicking on the button labeled Next, the license download form will be opened in a web browser, as shown in figure 1.9.

Click on the Download License button and then save the license file.

Back in the Workbench window, you will now see the dialog shown in 1.10.

Click on the Choose License File button, find the saved license file and select it. Then click on the Next button.
Accepting the license agreement

The end user license agreement (EULA) must be read and accepted as part of the installation process. figure 1.28.

Figure 1.11: The End User Licenense Agreement is presented during the installation process.

Please read the EULA text carefully, and if you agree to it, check the box next to the text I accept these terms. If further information is requested from you, please fill this in before clicking on the Finish button.

1.4.3 Import a license from a file

If you already have a license file associated with the host ID of your machine, it can be imported using this option.

When you have clicked on the Next button, you will see the dialog shown in 1.12.

Figure 1.12: Selecting a license file.
Click on the **Choose License File** button, locate the license file and selected it. Then click on the **Next** button.

**Accepting the license agreement**

The end user license agreement (EULA) must be read and accepted as part of the installation process. Figure 1.28.

![EULA Image](image)

Figure 1.13: *The End User License Agreement is presented during the installation process.*

Please read the EULA text carefully, and if you agree to it, check the box next to the text **I accept these terms**. If further information is requested from you, please fill this in before clicking on the **Finish** button.

### 1.4.4 Upgrade license

The option "Upgrade from an existing Workbench installation" can be convenient when you have been using another version of a licensed Workbench and the license is covered by our Maintenance, Upgrades and Support (MUS) program. Licenses not covered by MUS cannot be updated to support a new major Workbench release line.

If your license is covered our Maintenance, Upgrades and Support (MUS) program but you experience problems downloading a license for the new version of the software, please contact bioinformaticslicense@qiagen.com.

The Workbench will need direct access to the external network to use this option. If the Workbench cannot connect to the external network directly, please see section 1.4.6.

After selecting the "Upgrade from an existing Workbench installation" option, click on the **Next** button. The Workbench will search for an earlier installation of the same Workbench product you are upgrading to.
If it finds that installation, it will locate the existing license file and show information like that in figure 1.14.

When you click on the Next button, the Workbench checks if you are entitled to upgrade your license. This is done by contacting QIAGEN Aarhus servers.

If the earlier Workbench version could not be found, which can be the case if you have installed to a custom location or are upgrading from one Workbench product to another product replacing it\(^1\), then click on the "Choose a different License File" button. Navigate to where the older license file is, which will be in a subfolder called "licenses" within the installation area of the Workbench you are upgrading from. Select the license file and click on the "Open" button.

If the license selected can be updated, a message similar to that shown in figure 1.15 will be displayed. If there is a problem updating the selected license, a dialog will appear indicating this.

Click on the Next button and then choose how to proceed to get the updated license file.

---

\(^1\)In November 2018, the Biomedical Genomics Workbench was replaced by the CLC Genomics Workbench and a free plugin, Biomedical Genomics Analysis. Licenses for the Biomedical Genomics Workbench covered by MUS at that time can be used to download a valid license for the CLC Genomics Workbench, but the upgrade functionality is not able to automatically find the older license file.
In this dialog, there are two options:

- **Direct Download.** Download the license directly. This method requires that the Workbench has access to the external network.

- **Go to CLC License Download web page.** The online license download form will be opened in a web browser. This option is suitable for when downloading a license for use on another machine that does not have access to the external network, and thus cannot access the QIAGEN Aarhus servers.

After selecting your method of choice, click on the button labeled **Next**.

### Direct download

After choosing the **Direct Download** option and clicking on the button labeled **Next**, a dialog similar to that shown in figure 1.16 will appear if the license is successfully downloaded and installed.

![Figure 1.16: A license has been successfully downloaded and installed for use.](image)

When the license has been downloaded and installed, the **Next** button will be enabled.

If there is a problem, a dialog will appear indicating this.

### Go to license download web page

After choosing the **Go to CLC License Download web page** option and clicking on the button labeled **Next**, the license download form will be opened in a web browser, as shown in figure 1.17.

Click on the **Download License** button and then save the license file.

Back in the Workbench window, you will now see the dialog shown in 1.18.

Click on the **Choose License File** button, find the saved license file and select it. Then click on the **Next** button.

### Accepting the license agreement

The end user license agreement (EULA) must be read and accepted as part of the installation process. figure 1.28.
Please read the EULA text carefully, and if you agree to it, check the box next to the text **I accept these terms**. If further information is requested from you, please fill this in before clicking on the **Finish** button.

1.4.5 **Configure license server connection**

If your organization is running a CLC License Server, you can configure your Workbench to connect to it to get a license.

To configure the Workbench to connect to a CLC License Server, select the **Configure License Server connection** option and click on the **Next** button. A dialog for the license server connection configuration is then presented, as shown in figure 1.20.

The options in that dialog are:

- **Enable license server connection.** This box must be checked for the Workbench is to contact the CLC License Server to get a license for **CLC Genomics Workbench**.

- **Automatically detect license server.** By checking this option the Workbench will look for a CLC License Server accessible from the Workbench. Automatic server discovery sends UDP broadcasts from the Workbench on port 6200. Available license servers respond to the broadcast. The Workbench then uses TCP communication for to get a license, if one is available. Automatic server discovery works only on local networks and will not work on WAN or VPN connections. Automatic server discovery is not guaranteed to work on all networks. If you are working on an enterprise network on where local firewalls or routers cut off UDP broadcast traffic, then you may need to configure the details of the CLC License
CHAPTER 1. INTRODUCTION TO CLC GENOMICS WORKBENCH

Figure 1.19: The End User Lizense Agreement is presented during the installation process.

Figure 1.20: Connecting to a CLC License Server.

Server using the **Manually specify license server** option instead.

- **Manually specify license server.** Select this option to enter the details of the machine the CLC License Server software is running on, specifically:
  - **Host name.** The address of the machine the CLC License Server software is running on.
  - **Port.** The port used by the CLC License Server to receive requests.

- **Use custom username when requesting a license.** Optional. If this is checked, a username can be entered. That will be passed to the CLC License Server instead of the username of the account being used to run the Workbench.

- **Disable license borrowing on this computer.** Check this box if you do not want users of the computer to borrow a license. See section 1.4.5 for further details.
**Special note on modules needing a license**

This note concerns CLC Genomics Workbench 11.0 and higher, Biomedical Genomics Workbench 5.0 and higher and CLC Main Workbench 8.0 and higher.

A valid module license is needed to start a module tool, or a workflow including a module tool. Module licenses obtained through a License Server connection will be valid for four hours after starting the tool or the workflow. A process started (whether a module tool or a workflow including a module tool) will always be completed, even if its completion exceeds the four hours period where the license is valid.

If the tool or the workflow completes before the four hour validity period, it is possible to start a new tool or a workflow, and this will always refresh the validity of the license to a full four hours period. However, if the tool or the workflow completes after the four hour validity period, a new license will need to be requested after that to start the next tool or workflow.

These measures ensure that more licenses are available to active users, rather than blocked on an inactive computer, i.e., where the workbench would be open but not in use.

**Borrowing a license**

A *CLC Genomics Workbench* using a network license normally needs to maintain a connection to the CLC License Server. However, if allowed by the network license administrator, network licenses can be *borrowed* for offline use. During the period a license has been borrowed, there will be one less network license available for other users.

If CLC License Server administrator has chosen not to allow the borrowing of network licenses, then the information in this section is not relevant.

The Workbench must be connected to the CLC License Server at the point when the license is borrowed. The procedure for borrowing a license is:

1. Go to the Workbench menu option:
   **Help | License Manager**

2. Click on the "Borrow License" tab to display the dialog shown in figure **1.21**.

3. Select the license(s) that you wish to borrow by clicking in the checkboxes in the Borrow column in the License overview panel.
4. Choose the length of time you wish to borrow the license(s) for using the drop down list in the Borrow License tab. By default the maximum is 7 days, but network license administrators can specify a lower limit than this.

5. Click on the button labeled **Borrow Selected Licenses**.

6. Close the License Manager when you are done.

You can now go offline and continue working with the *CLC Genomics Workbench*. When the time period you borrowed the license for has elapsed, the network license will be again made available for other users. To continue using *CLC Genomics Workbench* with a license, you will need to connect to the network again so the Workbench can contact the CLC Licence Server.

You can return borrowed licenses early if you wish by started up the **License Manager**, opening the “Borrow License” tab, and clicking on the **Return Borrowed Licenses** button.

**Common issues when using a network license**

- **No license available at the moment** If all licenses are in use, you will see a dialog like that shown in figure 1.22 when you start up the Workbench.

![Figure 1.22: This window appears when there are no available network licenses for the software you are running.](image)

You will need to wait for at least one license to be returned before you can continue to work with a fully functional copy of the software. If running out of licenses is a frequent issue, you may wish to discuss this with your CLC License Server administrator.

Clicking on the **Viewing Mode** button in the dialog allows you to run the *CLC Genomics Workbench* for viewing data, and for basic analyses, import and export. Please see section 1.4.7 for further details.

- **Lost connection to the CLC License Server** If the Workbench connection to the CLC License Server is lost, you will see a dialog like that shown in figure 1.23.

If you have chosen the option to **Automatically detect license server** and you have not succeeded in connecting to the CLC License Server before, please check with your local IT support that automatic detection will be possible to do at your site. If it is not, you will need to specify the CLC License Server settings, as described earlier in this section.

If you have successfully contacted the CLC License Server from your Workbench previously, please consider discussing this issue with your CLC License Server administrator or your local IT support, for example, making sure that the CLC License Server is running and that your Workbench is able to connect to it.
CHAPTER 1. INTRODUCTION TO CLC GENOMICS WORKBENCH

Figure 1.23: Here, the Workbench is unable to establish a connection to a CLC License server.

There may be situations where you wish to use a different license or view information about the license(s) the Workbench is currently using. To do this, open the License Manager using the menu option:

Help | License Manager

The license manager is shown in figure 1.24.

This License Manager can be used to:

- See information about the license (e.g. the license type, when it expires, etc.)
- Configure the connect to a CLC License Server. Click on the Configure Network License button at the lower left corner to open the dialog seen in figure 1.20.
- Upgrade from an evaluation license. Click on the Upgrade Workbench License button to open the dialog shown in figure 1.1.
• Export license information to a text file.
• Borrow a license, relevant when using a network license.

If you wish to switch away from using a network license, click on the button to **Configure Network License** and uncheck the box beside the text **Enable license server connection** in the dialog. When you restart the Workbench, you can set up the new license as described in section 1.4.

### 1.4.6 Download a static license on a non-networked machine

To download a static license for a machine that does not have direct access to the external network, you can follow the steps below:

• Install the **CLC Genomics Workbench** on the machine you wish to run the software on.

• Start up the software as an administrative user and find the host ID of the machine that you will run the CLC Workbench on. You can see the host ID of the machine at the bottom of the License Assistant window in grey text, or, if working in Viewing Mode, by launching the **License Manager** from under the Workbench **Help** menu option.

• Make a copy of this host ID such that you can use it on a machine that has internet access.

• Go to a computer with internet access, open a browser window and go to the network license download web page:
  

• Paste in your license order ID and the host ID that you noted down in the relevant boxes on the web page.

• Click on ‘Download License’ and save the resulting .lic file.

• Open the Workbench on your non-networked machine. In the Workbench license manager choose ‘Import a license from a file’. In the resulting dialog click on the ’Choose License File’ button and then locate and select the .lic file you have just downloaded.

  If the License Manager does not start up by default, you can start it up by going to the menu option:

  **Help | License Manager**

• Click on the **Next** button and go through the remaining steps to install the license.

### 1.4.7 Viewing mode

Using a CLC Workbench in Viewing Mode is a free and easy way to access extensive data viewing capabilities, basic bioinformatics analysis tools, as well as import and export functionality.

**Data viewing**

---

\(^2\)For CLC Genomics Workbench 5.x and earlier or CLC Main Workbench 6.7.x and earlier, the license download page URL is [http://licensing.clcbio.com/LmxWSv1/GetLicenseFile](http://licensing.clcbio.com/LmxWSv1/GetLicenseFile)
CHAPTER 1. INTRODUCTION TO CLC GENOMICS WORKBENCH

Any data type supported by the Workbench being used can be viewed in Viewing Mode. Plugins or modules can also be installed when in Viewing Mode, expanding the range of data types supported.

Viewing Mode of the CLC Workbenches can be particularly useful when sharing data with colleagues or reviewers who wish to view and investigate data you have generated but who do not have access to a Workbench license.

Data import, export and analysis in Viewing Mode

When working in Viewing Mode, the Import and Export buttons in the top Toolbar are enabled, and standard import and export functionality for many bioinformatics data types is supported. Tools available can be seen in the Workbench Toolbox, as illustrated in figure 1.25.

Figure 1.25: Bioinformatics tools available when using Viewing Mode are found in the Toolbox.

Starting a CLC Workbench in Viewing Mode

A button labeled Viewing Mode is presented in the Workbench License Manager when a Workbench is started up without a license installed, as shown in figure 1.26. This button is also visible in message windows that appear if a Workbench is started up that has an expired license or that is configured to use a network license but all the available licenses have been checked out by others, as described in section 1.4.5.

Click on the Viewing Mode button to start up the Workbench in Viewing Mode.

To go from running in Viewing Mode to running a Workbench with its full functionality, it just needs to have access to a valid license. This can be done by installing a static license, or when using a network license, by restarting the Workbench when licenses are once again available.

1.4.8 Start in safe mode

If the program becomes unstable on start-up, you can start it in Safe mode. This is done by pressing and holding down the Shift button while the program starts.

When starting in safe mode, the user settings (e.g. the settings in the Side Panel) are deleted and cannot be restored. Your data stored in the Navigation Area is not deleted. When started in
CHAPTER 1. INTRODUCTION TO CLC GENOMICS WORKBENCH

1.5 Plugins

When you install CLC Genomics Workbench, it has a standard set of features. However, you can upgrade and customize the program using a variety of plugins.

As the range of plugins is continuously updated and expanded, they will not be listed here. Instead we refer to http://www.qiagenbioinformatics.com/plugins/ for a full list of plugins with descriptions of their functionalities.

**Note:** In order to install plugins and modules, the Workbench must be run in administrator mode. On Linux and Mac, it means you must be logged in as an administrator. On Windows, you can do this by right-clicking the program shortcut and choosing "Run as Administrator".

Plugins are installed and uninstalled using the plugin manager.

**Help in the Menu Bar | Plugins... ( ) or Plugins ( ) in the Toolbar**

The plugin manager has two tabs at the top:

- **Manage Plugins.** This is an overview of plugins that are installed.
- **Download Plugins.** This is an overview of available plugins on QIAGEN Aarhus server.

**1.5.1 Install**

To install a plugin, click the Download Plugins tab. This will display an overview of the plugins that are available for download and installation (see figure 1.27).

Select the plugin of interest to display additional information about the plugin on the right side of...
the dialog. Click Download and Install to add the plugin functionalities to your workbench.

**Accepting the license agreement**

The end user license agreement (EULA) must be read and accepted as part of the installation process. figure 1.28.

Please read the EULA text carefully, and if you agree to it, check the box next to the text I accept these terms. If further information is requested from you, please fill this in before clicking on the Finish button.

If the plugin is not shown on the server but you have the installer file on your computer (for example if you have downloaded it from our website), you can install the plugin by clicking the Install from File button at the bottom of the dialog and specifying the plugin *.cpa file saved on your computer.
When you close the dialog, you will be asked whether you wish to restart the workbench. The plugin will not be ready for use until you have restarted.

### 1.5.2 Uninstall

Plugins are uninstalled using the plugin manager:

**Help in the Menu Bar | Plugins... (PLUGIN) or Plugins (PLUGIN) in the Toolbar**

This will open the dialog shown in figure 1.29.

![Figure 1.29: The plugin manager with plugins installed.](image)

The installed plugins are shown in the Manage plugins tab of the plugin manager. To uninstall, select the plugin in the list and click **Uninstall**.

If you do not wish to completely uninstall the plugin, but you do not want it to be used next time you start the Workbench, click the **Disable** button.

When you close the dialog, you will be asked whether you wish to restart the workbench. The plugin will not be uninstalled until the workbench is restarted.

### 1.5.3 Updating plugins

If a new version of a plugin is available, you will get a notification during start-up as shown in figure 1.30.

In this list, select which plugins you wish to update, and click **Install Updates**. If you press **Cancel** you will be able to install the plugins later by clicking **Check for Updates** in the Plugin manager (see figure 1.29).

### 1.6 Network configuration

If you use a proxy server to access the Internet you must configure CLC Genomics Workbench to use this. Otherwise you will not be able to perform any online activities.

CLC Genomics Workbench supports the use of an HTTP-proxy and an anonymous SOCKS-proxy.
To configure your proxy settings, open the workbench, go to Edit | Preferences and choose the Advanced tab (figure 1.31).

You have the choice between an HTTP-proxy and a SOCKS-proxy. The workbench only supports the use of a SOCKS-proxy that does not require authorization.

You can select whether the proxy should be used also for FTP and HTTPS connections.

Exclude hosts can be used if there are some hosts that should be contacted directly and not through the proxy server. The value can be a list of hosts, each separated by a |, and in addition a wildcard character * can be used for matching. For example: *.foo.com|localhost.
If you have any problems with these settings you should contact your systems administrator.

### 1.7 CLC Server connection

Using a CLC Server, data can be stored centrally and analyses run on a central machine rather than on a personal computer. After logging into the CLC Server from a Workbench, data in CLC Server locations will be listed in the Workbench Navigation Area. When launching analyses that can be run on the CLC Server, you will be offered the choice of running them using the Workbench or the CLC Server.

To log into a CLC Server or to check on the status of an existing connection, go to:

File | CLC Server Connection

This will bring up a login dialog as shown in figure 1.32.

To log into a CLC Server, fill in the text fields. Your server administrator should be able to provide you with the necessary details. When you click on the Log In button, the Workbench will connect to the CLC Server if your credentials are accepted.

Your username and the server details will be saved between Workbench sessions. If you wish your password to be saved also, click in the box beside the Remember password box.

If you wish the Workbench to connect to the server automatically on startup, then check the box beside the option Log into CLC Server at Workbench startup. This option is only enabled when the Remember password option has been selected.

Further information about working with a CLC Server from a CLC Workbench is available in this manual:

- Launching tasks on a CLC Server is described in section 9.2.1.
- Monitoring processes sent to the CLC Server from a CLC Workbench is described in section 2.3.
• Viewing and working with data held on a CLC Server is described in section 3.1.1, and deleting data held on a CLC Server is described in section 3.1.7.

• Importing data to a CLC Server and exporting data held on a CLC Server is described in section 6.9.

For those logging into the CLC Server as a user with administrative privileges, an option called Manage Server Users and Groups... will be available. This is described in detail at http://resources.qiagenbioinformatics.com/manuals/clcserver/current/admin/index.php?manual=User_authentication_using_Workbench.html.

1.8 Getting started and latest improvements

CLC Genomics Workbench includes an extensive Help function, which can be found in the Help menu of the program’s Menu bar (or by pressing F1).

Tutorials describing hands-on examples of how to use the individual tools and features of the CLC Genomics Workbench can be found at http://www.qiagenbioinformatics.com/support/tutorials/. We also recommend our Online presentations where a product specialist demonstrates our software. This is a very easy way to get started using the program. Read more about video tutorials and other online presentations here: http://tv.qiagenbioinformatics.com/.

Finally, CLC Genomics Workbench is being constantly developed and improved. A detailed list of new features, improvements, bug fixes, and changes for the current version of CLC Genomics Workbench can be found at http://www.qiagenbioinformatics.com/products/latest-improvements/.

History of the CLC Workbenches

In November 2005, CLC bio releases two Workbenches: CLC Free Workbench and CLC Protein Workbench. CLC Protein Workbench is developed from the free version, giving it the well-tested user friendliness and look & feel with a range of more advanced analyses.

In March 2006, CLC DNA Workbench (formerly CLC Gene Workbench) and CLC Main Workbench are added to the product portfolio of CLC bio. Like CLC Protein Workbench, CLC DNA Workbench builds on CLC Free Workbench. It shares some of the advanced product features of CLC Protein Workbench, and has additional advanced features. CLC Main Workbench holds all basic and advanced features of the CLC Workbenches.

In June 2007, CLC RNA Workbench is released as a sister product of CLC Protein Workbench and CLC DNA Workbench. CLC Main Workbench now also includes all the features of CLC RNA Workbench.

In March 2008, CLC Free Workbench changes name to CLC Sequence Viewer.

In June 2008, the first version of the CLC Genomics Workbench is released due to an extraordinary demand for software capable of handling sequencing data from all new high-throughput sequencing platforms such as Roche-454, Illumina and SOLiD in addition to Sanger reads and hybrid data.

In December 2006, CLC bio releases a Software Developer Kit which makes it possible for anybody with a knowledge of programming in Java to develop plugins. The plugins are fully
integrated with the CLC Workbenches and the Viewer and provide an easy way to customize and extend their functionalities.

In April 2012, CLC Protein Workbench, CLC DNA Workbench and CLC RNA Workbench are discontinued. All customers with a valid license for any of these products are offered an upgrade to the CLC Main Workbench.

In February 2014, CLC bio expands the product repertoire with the release of CLC Drug Discovery Workbench, a product that enables studies of protein-ligand interactions for drug discovery.

In April 2014, CLC bio releases CLC Cancer Research Workbench, a product that contains streamlined data analysis workflows with integrated trimming and quality control tailored to meet the requirements of clinicians and researchers working within the cancer field.

In April 2015, CLC Cancer Research Workbench is renamed to Biomedical Genomics Workbench to reflect the inclusion of tools addressing the requirements of clinicians and researchers working within the hereditary disease field in addition to the tools designed for those working within the cancer field.

In June 2017, Viewing Mode is introduced in all commercial CLC Workbenches. This mode is available when a Workbench is launched without a valid license. In this mode, data can be viewed and some basic analyses equivalent to those available in the free CLC Sequence Viewer, can be run.

In January 2018, CLC Drug Discovery Workbench is discontinued.

In November 2018, the Biomedical Genomics Analysis plugin is released for use with CLC Genomics Workbench. With the Biomedical Genomics Analysis plugin installed, CLC Genomics Workbench becomes the delivery mechanism for all biomedical analyses previously delivered by Biomedical Genomics Workbench and some associated plugins. Biomedical Genomics Workbench is correspondingly discontinued, and all customers with valid licenses for Biomedical Genomics Workbench can use them for CLC Genomics Workbench.
Part II

Core Functionalities
## Chapter 2

### User interface

This chapter provides an overview of the different areas in the user interface of *CLC Genomics Workbench*. As can be seen from figure 2.1 this includes:

- a **Navigation Area** where files are sorted;
- a **Toolbox** that can be opened as such, or as a Processes or a Favorites tab;
- a **View Area** with one or more tabs open;
- a **Side Panel** where it is possible to change the settings for the currently opened View;

• a **Menu Bar** to access various function, and a **Toolbar** that highlights the most common actions;

• a **Status Bar** at the bottom of the screen that indicates the status of the workbench (processing a job, or idle) and additional information that are View-dependant.

![Figure 2.1: The user interface.](image)

### 2.1 View Area

The **View Area** is the central part of the screen, displaying your current work. The View Area may consist of one or more **Views**, represented by **tabs** at the top of the View Area. In figure 2.2, four views are displayed: three as tabs in the upper view, and one in an horizontal split view. The tab currently selected, i.e., active, is indicated by a blue bar underneath the tab (here the bottom tab open in the bottom view).

Switch tabs in View Area using the following shortcuts Ctrl + PageUp or PageDown (or ⌘ + PageUp or PageDown on Mac).

Several operations can be performed by right-click menus that can be activated from the tab, or by using the icon list at the bottom of each view.

#### 2.1.1 Open view

**Elements**

Opening an element can be done in a number of ways:

- **double-click an element in the Navigation Area**
- **or select an element in the Navigation Area** | **Show** or **Ctrl + O** (⌘ + B on Mac)

Opening an element while another element is already open in the View Area will show the new element in front of the other. The element that was already open can be brought to front by
CHAPTER 2. USER INTERFACE

Figure 2.2: A View Area can enclose several views, each view indicated with a tab.

clicking its tab.

Views

Each element can be shown in different ways. A sequence, for example, can be shown as linear, circular, text, etc.

For example, to see a linear sequence in a circular view, open the sequence as linear in the View Area and

**Click Show As Circular (○) at the lower left part of the view**

The buttons used for switching views are shown in figure 2.3. They are element-dependent, meaning that different elements may have different buttons available. You can switch from one to the other sequentially by clicking Ctrl + Shift + PageUp or Ctrl + Shift + PageDown.

Figure 2.3: The buttons shown at the bottom of a view of a nucleotide sequence. You can click the buttons to change the view to a circular view or a history view.

Split views

If the sequence is already open in a linear view ( ), and you wish to see both a circular and a linear view, you can split the views very easily:

**Press Ctrl (⌘ on Mac) while you Click Show As Circular (○) at the lower left part of the view**

This will open a split view with a linear view at the bottom and a circular view at the top (see
You can also show a circular view of a sequence without opening the sequence first:

Select the sequence in the Navigation Area | Show (**) | As Circular (**)

2.1.2 History and Elements Info views

The two buttons to the right hand side of the toolbar are Show History (**) and Show Element Info (**).

The History view is a textual log of all operations you make in the program. If for example you rename a sequence, align sequences, create a phylogenetic tree or translate a sequence, you can always go back and check what you have done. In this way, you are able to document and reproduce previous operations.

When an element’s history is opened, the newest change is submitted in the top of the view (figure 2.4).

The following information is available:

- **Originates from workflow** (optional). In cases where the file was generated by a workflow, the first line will state the Name and Version number of that workflow.

- **Title**. The action that the user performed.

- **Date and time**. Date and time for the operation. The date and time are displayed according to your locale settings (see section 4.1).
• **Version.** The workbench type and version that has been used.

• **User.** The user who performed the operation. If you import some data created by another person in a CLC Workbench, that person’s name will be shown.

• **Parameters.** Details about the action performed. This could be the parameters that were chosen for an analysis.

• **Comments.** By clicking **Edit** you can enter your own comments regarding this entry in the history. These comments are saved.

• **Originates from.** This information is usually shown at the bottom of an element’s history. Here, you can see which elements the current element originates from. For example, if you have created an alignment of three sequences, the three sequences are shown here. Clicking the element selects it in the Navigation Area, and clicking the “history” link opens the element’s own history.

When an element’s info is open you can check current information about the element, and in particular the potential association of the data you are looking at with metadata. To learn more about the **Show Element Info** button, see section 11.4 and see section 3.2.4.

### 2.1.3 Close views

When a view is closed, the **View Area** remains open as long as there is at least one open view.

A view is closed by:

- **Right-click the tab** | **Close** or **Select the view** | **Ctrl + W**

By right-clicking a tab, the following close options exist (figure 2.5).

![Figure 2.5: By right-clicking a tab, several close options are available.](image)

- **Close.** See above.

- **Close Other Tabs.** Closes all other tabs, in all tab areas, except the one that is selected.
• **Close Tab Area.** Closes all tabs in the tab area, but not the tabs that are in split view.

• **Close All Tabs.** Closes all tabs, in all tab areas. Leaves an empty workspace.

### 2.1.4 Save changes in a view

When a new view is created, an * in front of the name of the view in the tab indicates that the element has not been saved yet. Similarly, when changes to an element are made in a view, an * is added before the element name on the tab and the element name is shown in **bold and italic** in the Navigation Area (figure 2.6).

![Figure 2.6: An * on a tab name always indicates that the view is unsaved. In this case, an existing element was edited but not saved yet, so the element's name is also highlighted in bold and italic in the Navigation Area.](image)

The **Save** function may be activated in two ways: Select the tab of the view you want to save and **Save (⌘ S)** or **Ctrl + S (⌘ + S on Mac)**

If you close a tab of a view containing an element that was edited, you will be asked if you want to save.

When saving an element from a new view that has not been opened from the Navigation Area, a save dialog appears (figure 2.7). In this dialog, you can name the element and select the folder in which you want to save the element.

![Figure 2.7: Save dialog. The new element has been name "New element that needs to be saved" and will be saved in the "Example Data" folder.](image)
2.1.5 Undo/Redo

If you make a change to an element in a view, e.g. remove an annotation in a sequence or modify a tree, you can undo the action. In general, Undo applies to all changes you can make when right-clicking in a view. Undo is done by:

Click undo (.undo icon) in the Toolbar or Ctrl + Z

If you want to undo several actions, just repeat the steps above.

To reverse the undo action:

Click the redo icon in the Toolbar or Ctrl + Y

Note! Actions in the Navigation Area, e.g., renaming and moving elements, cannot be undone. However, you can restore deleted elements (see section 3.1.7).

You can set the number of possible undo actions in the Preferences dialog (see section 4).

2.1.6 Arrange views in View Area

To provide more space for viewing data, you can hide Navigation Area and Toolbox by clicking the hide icon (hide icon) at the top of the Navigation Area. You can also hide the Side Panel using the same icon at the top of the Side Panel.

Views are arranged in the View Area by their tabs. The order of the views can be changed using drag and drop.

If a tab is dragged into a view, the area where the tab will be placed is highlighted blue. The blue area can be a tab bar in another view, or the bottom of an existing view. In that case, the tab will be moved to a new split view.

You can also split a View Area horizontally or vertically using the menus.

Splitting horizontally may be done this way:

right-click a tab of the view | View | Split Horizontally

This action opens the chosen view below the existing view. When the split is made vertically, the new view opens to the right of the existing view (see figure 2.8).

Splitting the View Area can be undone by dragging the tab of the bottom view to the tab of the top view, or by using the Maximize/Restore View function.

Select the view you want to maximize, and click

View | Maximize/restore View or Ctrl + M

or right-click the tab | View | Maximize/restore View

or double-click the tab of view

The following restores the size of the view:

View | Maximize/restore View or Ctrl + M

or double-click title of view
2.1.7 Moving a view to a different screen

Using multiple screens can be a great benefit when analyzing data with the CLC Genomics Workbench. You can move a view to another screen by dragging the tab of the view and dropping it outside the workbench window. Alternatively, you can right-click in the view area or on the tab itself and select View | Move to New Window from the context menu.

An example is shown in figure 2.9, where the main Workbench window shows a table of open reading frames, and the screen to the right is used to display the sequence and annotations.

You can make more detached windows, by dropping tabs outside the open workbench windows, or you can drag more tabs to a detached window. To get a tab back to the main workbench window, just drag the detached tab back, and drop it next to the other tabs in the top of the view area. Note: You should not drag the detached window header, just the tab itself.
2.1.8 Side Panel

The Side Panel allows you to change the way the content of a view is displayed. The options in the Side Panel depend on the kind of data in the view, and they are described in the relevant sections about sequences, alignments, trees etc.

Figure 2.10 shows the default Side Panel for a protein sequence. It is organized into palettes.

Figure 2.10: The default view of the Side Panel when opening a protein sequence.

In this example, there is one palette for Sequence layout, one for Annotation Layout etc. These palettes can be re-organized by dragging the palette name with the mouse and dropping it where you want it to be. They can either be situated next to each other, so that you can switch between them, or they can be listed on top of each other, so that expanding one of the palettes will push the palettes below further down.

In addition, they can be moved away from the Side Panel and placed anywhere on the screen as shown in figure 2.11.

In this example, the Motifs palette has been placed on top of the sequence view together with the the Residue coloring palette. In the Side Panel to the right, the Find palette has been put on top.

In order to make all palettes dock in the Side Panel again, click the Dock Side Panel icon (←). You can completely hide the Side Panel by clicking the Hide Side Panel icon (▶).

At the bottom of the Side Panel (see figure 2.12) there are a number of icons used to:

- Collapse all settings (≡).
Figure 2.11: Palettes can be organized in the Side Panel as you like or placed anywhere on the screen.

Figure 2.12: Functionalities found at the bottom of the Side Panel.

- Expand all settings (□).  
- Dock all palettes (□□)  
- Get Help for the particular view and settings  
- Save the settings of the Side Panel or apply already saved settings. Changes made to the Side Panel, including the organization of palettes, will not be saved when you save the view. Learn how to save Side Panel settings in section 4.6.

2.2 Zoom and selection in View Area

All views except tabular and text views support zooming. Figure 2.13 shows the zoom tools, located at the bottom right corner of the view.

The zoom tools consist of some shortcuts for zooming to fit the width of the view ( ), zoom to 100 % to see details ( ), zoom to a selection ( ), a zoom slider, and two mouse mode buttons ( ) ( ).

The slider reflects the current zoom level and can be used to quickly adjust this. For more fine-grained control of the zoom level, move the mouse upwards while sliding.
The sections below describes how to use these tools as well as other ways of zooming and navigating data.

Please note that when working with protein 3D structures, there are specific ways of controlling zooming and navigation as explained in section 13.2.

### 2.2.1 Zoom in

There are six ways of zooming in:

- Click Zoom in mode (Ctrl+2) in the zoom tools | click the location in the view that you want to zoom in on
- Click Zoom in mode (Ctrl+2) in the zoom tools | click-and-drag a box around a part of the view | the view now zooms in on the part you selected
- Press ‘+’ on your keyboard
- Move the zoom slider located in the zoom tools
- Click the plus icon in the zoom tools

The last option for zooming in is only available if you have a mouse with a scroll wheel:

- Press and hold Ctrl (⌘ on Mac) | Move the scroll wheel on your mouse forward

**Note!** You might have to click in the view before you can use the keyboard or the scroll wheel to zoom.

If you press the **Shift** button on your keyboard while in zoom mode, the zoom function is reversed.

If you want to zoom in to 100 % to see the data at base level, click the **Zoom to base level** icon.

### 2.2.2 Zoom out

It is possible to zoom out in different ways:

- Click Zoom out mode (Ctrl+3) in the zoom tools | click in the view
- Press ‘-’ on your keyboard
- Move the zoom slider located in the zoom tools
- Click the minus icon in the zoom tools
The last option for zooming out is only available if you have a mouse with a scroll wheel:

- **Press and hold Ctrl (⌘ on Mac) | Move the scroll wheel on your mouse backwards**

**Note!** You might have to click in the view before you can use the keyboard or the scroll wheel to zoom.

If you want to zoom out to see all the data, click the **Zoom to Fit** icon.

If you press **Shift** while clicking in a **View**, the zoom function is reversed. Hence, clicking on a sequence in this way while the **Zoom out** mode toolbar item is selected, zooms in instead of zooming out.

### 2.2.3 Selecting, panning and zooming

In the zoom tools, you can control which mouse mode to use. The default is **Selection mode** which is used for selecting data in a view. Next to the selection mode, you can select the **Zoom in mode** as described in section 2.2.1. If you press and hold this button, two other modes become available as shown in figure 2.14:

- **Panning** is used for dragging the view with the mouse as a way of scrolling.
- **Zoom out** is used to change the mouse mode so that whenever you click the view, it zooms out.

![Additional mouse modes can be found in the zoom tools when right-clicking on the magnifying glass.](image)

If you hold the mouse over the selection and zoom tools, tooltips will appear that provide further information about how to use the tools.

The mouse modes only apply when the mouse is within the view where they are selected.

The **Selection mode** can also be invoked with the keyboard shortcut Ctrl+1, while the **Panning mode** can be invoked with Ctrl+4.

For some views, if you have made a selection, there is a **Zoom to Selection** button, which allows you to zoom and scroll directly to fit the view to the selection.

### 2.3 Toolbox and Status Bar

The **Toolbox** is placed in the left side of the user interface of **CLC Genomics Workbench** below the Navigation Area. It can be seen as a **Processes tab**, a **Toolbox tab** and a **Favorites tab**.

The Toolbox can be hidden, so that the Navigation Area is enlarged:

Click the **Hide Toolbox** button or
View | Show/Hide Toolbox

This path gives you the choice to hide the Toolbox, or to selectively hide any of the tabs associated to the Toolbox.

2.3.1 Processes

Click on the Processes tab to select it. In this tab, running Workbench processes and any processes previously run in the Workbench session are shown. Server processes are also shown, as described further below.

Running Workbench processes paused and resumed, or stopped. These actions are taken by clicking the small icon ( ) next to the process (see figure 2.15).

Figure 2.15: A database search and an alignment calculation are running. Clicking the small icon next to the process allow you to stop, pause and resume processes.

Stopped and paused processes are not deleted from the Processes tab during a Workbench session, but they can be removed by right clicking in the Processes tab and selecting the option "Remove Finished Processes" or by going to the option in the main menu system:

View | Remove Finished Processes (X)

Other menu options that appear when the small icon ( ) next to a process in the Processes tab is clicked are:

- **Show results.** If you have chosen to save the results (see section 9.2), you will be able to open the results directly from the process by clicking this option.

- **Find results.** If you have chosen to save the results (see section 9.2), you will be able to highlight the results in the Navigation Area.

- **Show Log Information.** Clicking on this option opens a log of the progress of the process. This is the same log that opens if the option Open Log option is selected when launching a task.

- **Show Messages.** Analyses may produce messages when processing your data. Such messages appear briefly in black dialogs in the lower left corner of the Workbench. Clicking on this option shows these messages again.

If you close the program while Workbench processes are still running, a dialog will ask if you are sure that you want to close the program. Closing the program will stop these processes and they
cannot be directly restarted when you re-open the Workbench. You would need to launch any
tasks interrupted this way again. Running server processes are not stopped, as described below.

Processes submitted to a CLC Server

Processes you have submitted to a CLC Server are listed in the Processes tab when the
Workbench is logged into the server. Such processes have a server icon ({$}) to their left, rather
than icons specific to the analysis being run. Processes that are queued or running on a CLC Server will reappear in the Workbench processes tab if you restart the Workbench (and log into
the server). CLC Server processes already finished when you close the Workbench will not be
shown again in the processes tab when you restart your Workbench.

Like running Workbench processes, processes running on a CLC Server can be stopped, by
selecting clicking the small icon ({$}) next to the process and selecting the option "Stop". However, unlike jobs running on a Workbench, they cannot be paused or resumed.

Of note when running jobs on a CLC Server: If you choose the option "On my local disk or a
place I have access to" when launching an import task, then the Workbench must maintain its
connection to the CLC Server during the first part of the import process, data upload. If you try to
close the Workbench during this phase, you will see a warning dialog. You can see what stage
tasks are at in the Processes tab. Data upload from the Workbench to the server runs as a local,
Workbench process. When the upload stage is complete, a new process for the import is started.
This import process will have a server icon ({$}) to the left of it. At this point, you can disconnect
or close your Workbench without affecting the import.

2.3.2 Toolbox

The tools in the toolbox can be accessed by double-clicking, right clicking and choosing "Run",
or by dragging elements from the Navigation Area to an item in the Toolbox.

In addition, a Launch button ({$}) enables quick launch of tools in CLC Genomics Workbench.
You can also press Ctrl + Shift + T (⌘ + Shift + T on Mac) to show the quick launch dialog (see
figure 2.16).

When the dialog is opened, you can start typing search text in the text field at the top. This will
bring up the list of tools that match this text either in the name, description or location in the
Toolbox. We also match newer tools to older names when the names were updated from one
version of the Workbench to the other.

In the example shown in figure 2.17, typing create shows a list of tools involving the word
"create", and the arrow keys or mouse can be used for selecting and starting a tool.

2.3.3 Favorites

Next to the Toolbox tab, you find the Favorites tab. This can be used for organizing and getting
quick access to the tools you use the most. It consists of two parts as shown in figure 2.18.

Favorites You can manually add tools to the favorites menu simply by right-clicking the tool in
the Toolbox. You can also right-click the Favorites folder itself and select Add Tool. To
remove a tool, right-click and select Remove from Favorites. Note that you can also add
complete folders to the favorites.
CHAPTER 2. USER INTERFACE

2.3.4 Status Bar

As can be seen from figure 2.1, the Status Bar is located at the bottom of the window. In the left side of the bar is an indication of whether the computer is making calculations or whether it is idle. The right side of the Status Bar indicates various information depending on the context: it can be the size of a region selected on a sequence, the variant at the position where the cursor stands, or how many rows are selected in a table.
2.4 Workspace

If you are working on a project and have arranged the views for this project, you can save this arrangement using Workspaces. A Workspace remembers the way you have arranged the views, and you can switch between different workspaces.

The Navigation Area always contains the same data across workspaces. It is, however, possible to open different folders in the different workspaces. Consequently, the program allows you to display different clusters of the data in separate workspaces.

All workspaces are automatically saved when closing down CLC Genomics Workbench. The next time you run the program, the workspaces are reopened exactly as you left them.

Note! It is not possible to run more than one version of CLC Genomics Workbench at a time. Use two or more workspaces instead.

Create Workspace  When working with large amounts of data, it might be a good idea to split the work into two or more workspaces. As default the CLC Genomics Workbench opens one workspace. Additional workspaces are created in the following way:

Workspace in the Menu Bar | Create Workspace | enter name of Workspace | OK

Initially, the folders of the Navigation Area are collapsed and the View Area is empty and ready to work with.

Select Workspace  When there is more than one workspace in the CLC Genomics Workbench, there are two ways to switch between them:

Workspace (>Create) in the Toolbar | Select the Workspace to activate

or Workspace in the Menu Bar | Select Workspace ((Create) | choose which Workspace to activate | OK

Delete Workspace  Deleting a workspace can be done in the following way:

Workspace in the Menu Bar | Delete Workspace | choose which Workspace to delete | OK

Note! Be careful to select the right Workspace when deleting. The delete action cannot be undone. (However, no data is lost, because a workspace is only a representation of data.)
It is not possible to delete the default workspace.

2.5 List of shortcuts

The keyboard shortcuts in CLC Genomics Workbench are listed below.
<table>
<thead>
<tr>
<th>Action</th>
<th>Windows/Linux</th>
<th>macOS</th>
</tr>

This chapter explains the data management features of CLC Genomics Workbench. The first section explains the basics of the data organization and the Navigation Area. The next section explains how to set up custom attributes for the data that can be used for more advanced data management. Finally, there is a section about how to search through local data.
CHAPTER 3. DATA MANAGEMENT AND SEARCH

3.1 Navigation Area

The Navigation Area (see figure 3.1) is used for organizing and navigating data. Its behavior is similar to the way files and folders are usually displayed on your computer.

![Navigation Area](image)

Figure 3.1: The Navigation Area.

Just above the area with the listing of data are 4 icons. From left to right, these are:

- **Collapse all** ( Collapse all). This closes all the open folders in the Navigation Area.
- **Add File Location** ( Add File Location). This is explained in section 3.1.1.
- The Create Folder icon ( Create Folder), which is used to create new folders within a configured File Location.
- The Update All icon ( Update All), which refreshes the view of the Navigation Area.

To provide more space for viewing data, you can hide Navigation Area and the Toolbox by clicking on the hide icon ( Hide ) in the top right hand side of the Navigation Area.

3.1.1 Data structure

The data in the Navigation Area is organized into a number of Locations. When the CLC Genomics Workbench is started for the first time, there is one location called CLC_Data (unless your computer administrator has configured the installation otherwise).

A Workbench data location represents a folder on the computer: The data shown under a Workbench location in the Navigation Area is stored on the computer, in the folder the location points to.

This is explained visually in figure 3.2. The full path to the system folder can be seen by mousing over the data location folder icon as shown in figure 3.3.

Data held on a CLC Server
CHAPTER 3. DATA MANAGEMENT AND SEARCH

Figure 3.2: In this example the location called “CLC_Data” points to the folder at C:\Users\<username>\CLC_Data.

Figure 3.3: Mousing over the location called ‘CLC_Data’ shows the full path to the system folder, which in this case is C:\Users\<username>\CLC_Data.

If you have logged into a CLC Server from your Workbench, then data stored on the CLC Server will also be listed in the Workbench Navigation Area, as illustrated in figure 3.4.

Figure 3.4: Data areas on the CLC Server are highlighted with blue square icons in the Navigation Area.

Adding locations

Per default, there is one location in the Navigation Area called CLC_Data. It points to the following folder:

- On Windows: C:\Users\<your_username>\CLC_Data
- On Mac: ~/CLC_Data
- On Linux: /homefolder/CLC_Data
You can easily add more locations to the **Navigation Area**:

**File | New | Location (    )**

This will bring up a dialog where you can navigate to the folder you wish to use as your new location (see figure 3.5).

![Figure 3.5: Navigating to a folder to use as a new location.](image)

When you click **Open**, the new location is added to the **Navigation Area** as shown in figure 3.6.

![Figure 3.6: The new location has been added.](image)

The name of the new location will be the name of the folder selected for the location. To see where the folder is located on your computer, place your mouse cursor on the location icon (    ) for a second. This will show the path to the location.

You can configure any folder on a network drive or a removable drive as a File Location. Such a location will appear inactive if the relevant drive is not available when you start up the Workbench. Once the drive is available, click on the Update All symbol (    ) at the top of the Navigation area. This refreshes the view of the Navigation Area, and all available Locations will then be shown as active. There can be sometimes be a short delay before the interface update completes.

**Sharing data** is possible when a network drive is available to multiple Workbenches. In this case, you can add the same folder as a Data Location on each Workbench. However, it is important to note that data sharing is not actively supported: we do not support concurrent alteration of data and while the software will often detect this situation and handle it appropriately, by for example only allowing read access to all but the one party editing the file, we do not guarantee this. In addition, any functionality that involves using the data search indices, (e.g. search functionality, associating metadata with data), will not work properly for shared data locations. Re-indexing a Data Location can help in the short term, but as soon as a new file is created by another piece of software, the index will be out of date. If you decide to share data via Workbenches this way, it is vital that any Workbench that adds a Data Location already used by other Workbenches uses the exact same folder from the network drive file system hierarchy as the other Workbenches have used. Indicating a folder higher up or lower down in the hierarchy will
cause problems with the indexing of the files, meaning that newly created objects by Workbench A will not be found by Workbench B and vice versa.

**Opening data**

The elements in the **Navigation Area** are opened by:

- **Double-clicking on the element**
- **Clicking once on the element** | **Show ()** in the Toolbar
- **Clicking once on the element** | **Right-click on the element** | **Show ()**
- **Clicking once on the element** | **Right-click on the element** | **Show (the one without an icon)** | **Select the desired way to view the element from the menu that appears when mousing over "Show"**

This will open a view in the **View Area**, which is described in section 2.1.

**Adding data**

Data can be added to the **Navigation Area** in a number of ways. Files can be imported from the file system (see chapter 6). Furthermore, an element can be added by dragging it into the **Navigation Area**. This could be views that are open, elements on lists, e.g. search hits or sequence lists, and files located on your computer.

Finally, you can add data by adding a new location (see section 3.1.1).

If a file or another element is dropped on a folder, it is placed at the bottom of the folder. If it is dropped on another element, it will be placed just below that element.

If the element already exists in the **Navigation Area** a copy will be created with the name extension "-1", "-2" etc. if more than one copy exist.

### 3.1.2 Create new folders

In order to organize your files, they can be placed in folders. Creating a new folder can be done in two ways:

- **right-click an element in the Navigation Area** | **New** | **Folder ()**
- **File** | **New** | **Folder ()**

If a folder is selected in the **Navigation Area** when adding a new folder, the new folder is added at the bottom of this folder. If an element is selected, the new folder is added right above that element.

You can move the folder manually by selecting it and dragging it to the desired destination.

### 3.1.3 Sorting folders

You can sort the elements in a folder alphabetically:

- **right-click the folder** | **Sort Folder**
On Windows, subfolders will be placed at the top of the folder, and the rest of the elements will be listed below in alphabetical order. On Mac, both subfolders and other elements are listed together in alphabetical order.

### 3.1.4 Multiselecting elements

Multiselecting elements means that you select more than one element at the same time. This can be done in the following ways:

- Holding down the `<Ctrl>` key (⌘ on Mac) while clicking on multiple elements selects the elements that have been clicked.
- Selecting one element, and selecting another element while holding down the `<Shift>` key selects all the elements listed between the two locations (the two end locations included).
- Selecting one element, and moving the cursor with the arrow-keys while holding down the `<Shift>` key, enables you to increase the number of elements selected.

### 3.1.5 Moving and copying elements

Elements can be moved and copied in several ways:

- Using **Copy** (⌘), **Cut** (⌘) and **Paste** (⌘) from the **Edit** menu.
- Using `Ctrl + C` (⌘ + C on Mac), `Ctrl + X` (⌘ + X on Mac) and `Ctrl + V` (⌘ + V on Mac).
- Using **Copy** (⌘), **Cut** (⌘) and **Paste** (⌘) in the **Toolbar**.
- Using drag and drop to move elements.
- Using drag and drop while pressing Ctrl / Command to copy elements.

In the following, all of these possibilities for moving and copying elements are described in further detail.

**Copy, cut and paste functions**

Copies of elements and folders can be made with the copy/paste function which can be applied in a number of ways:

```
select the files to copy | right-click one of the selected files | Copy (⌘) | right-click the location to insert files into | Paste (⌘)
```

or

```
select the files to copy | Ctrl + C (⌘ + C on Mac) | select where to insert files | Ctrl + P (⌘ + P on Mac)
```

or

```
select the files to copy | Edit in the Menu Bar | Copy (⌘) | select where to insert files | Edit in the Menu Bar | Paste (⌘)
```

If there is already an element of that name, the pasted element will be renamed by appending a number at the end of the name.

Elements can also be moved instead of copied. This is done with the cut/paste function:
select the files to cut | right-click one of the selected files | Cut (⌘) | right-click the location to insert files into | Paste (⌘)

or select the files to cut | Ctrl + X (⌘ + X on Mac) | select where to insert files | Ctrl + V (⌘ + V on Mac)

When you have cut the element, it is "grayed out" until you activate the paste function. If you change your mind, you can revert the cut command by copying another element.

Note that if you move data between locations, the original data is kept. This means that you are essentially doing a copy instead of a move operation.

Move using drag and drop

Using drag and drop in the Navigation Area, as well as in general, is a four-step process:

 click the element | click on the element again, and hold left mouse button | drag the element to the desired location | let go of mouse button

This allows you to:

- Move elements between different folders in the Navigation Area
- Drag from the Navigation Area to the View Area: A new view is opened in an existing View Area if the element is dragged from the Navigation Area and dropped next to the tab(s) in that View Area.
- Drag from the View Area to the Navigation Area: The element, e.g. a sequence, alignment, search report etc. is saved where it is dropped. If the element already exists, you are asked whether you want to save a copy. You drag from the View Area by dragging the tab of the desired element.

Use of drag and drop is supported throughout the program, also to open and re-arrange views (see section 2.1.6).

Note that if you move data between locations, the original data is kept. This means that you are essentially doing a copy instead of a move operation.

Copy using drag and drop

To copy instead of move using drag and drop, hold the Ctrl (⌘ on Mac) key while dragging:

 click the element | click on the element again, and hold left mouse button | drag the element to the desired location | press Ctrl (⌘ on Mac) while you let go of mouse button

3.1.6 Change element names

This section describes two ways of changing the names of sequences in the Navigation Area. In the first part, the sequences themselves are not changed - it’s their representation that changes. The second part describes how to change the name of the element.
CHAPTER 3. DATA MANAGEMENT AND SEARCH

Change how sequences are displayed

Sequence elements can be displayed in the Navigation Area with different types of information:

- Name (this is the default information to be shown).
- Accession (sequences downloaded from databases like GenBank have an accession number).
- Latin name.
- Latin name (accession).
- Common name.
- Common name (accession).

Whether sequences can be displayed with this information depends on their origin. Sequences that you have created yourself or imported might not include this information, and you will only be able to see them represented by their name. However, sequences downloaded from databases like GenBank will include this information. To change how sequences are displayed:

right-click any element or folder in the Navigation Area | Sequence Representation | select format

This will only affect sequence elements, and the display of other types of elements, e.g. alignments, trees and external files, will be not be changed. If a sequence does not have this information, there will be no text next to the sequence icon.

Rename element

Renaming a folder or an element in the Navigation Area can be done in two different ways:

select the element | Edit in the Menu Bar | Rename

or select the element | F2

When you can rename the element, you can see that the text is selected and you can move the cursor back and forth in the text. When the editing of the name has finished; press Enter or select another element in the Navigation Area. If you want to discard the changes instead, press the Esc-key.

For renaming annotations instead of folders or elements, see section 11.3.3.

3.1.7 Delete, restore and remove elements

When one deletes data held in a Workbench data location, it is moved to the recycle bin within that data location. Each data location has its own recycle bin. From the recycle bin, data can then be restored, or completely removed. Removal of data from the recycle bin frees disk space.

Deleting a folder or an element from a Workbench data location can be done in two ways:

right-click the element | Delete (X)

or select the element | press Delete key
CHAPTER 3. DATA MANAGEMENT AND SEARCH

This will cause the element to be moved to the Recycle Bin (🗑️) where it is kept until the recycle bin is emptied or until you choose to restore the data object to your data location.

For deleting annotations instead of folders or elements, see section 11.3.4.

**Items in a recycle bin can be restored** in two ways:

- Drag the elements with the mouse into the folder where they used to be.
- or **select the element | right click and choose the option Restore**.

Once restored, you can continue to work with that data.

**All contents of the recycle bin can be removed** by choosing to empty the recycle bin:

**Edit in the Menu Bar | Empty Recycle Bin (🗑️)**

This deletes the data and frees up disk space.

**Note!** This cannot be undone. Data is not recoverable after it is removed by emptying the recycle bin.

**Deleting data held on a CLC Server**

You can delete data that you have "write" permission for from CLC Server data areas when logged into a server from your Workbench. The method of deleting data is the same as described above when deleting data held in Workbench data locations. The deleted data is placed in a Recycle bin (🗑️) on the CLC Server. The data in the server-based recycle bin can only be accessed by you and the server administrator. Note that the server administrator may have configured the recycle bin to be automatically emptied at regular intervals.

### 3.1.8 Show folder elements in a table

A location or a folder might contain large amounts of elements. It is possible to view their elements in the **View Area**:

- select a folder or location | Show (🗂️) in the Toolbar
- or
- select a folder or location | right click on the folder and select Show (🗂️) | Contents (🗂️)

An example is shown in figure 3.7.

When the elements are shown in the view, they can be sorted by clicking the heading of each of the columns. You can further refine the sorting by pressing Ctrl (⌘ on Mac) while clicking the heading of another column.

Sorting the elements in a view does not affect the ordering of the elements in the **Navigation Area**.

**Note!** The view only displays one "layer" at a time: the content of subfolders is not visible in this view. Also note that only sequences have the full span of information like organism etc.
Batch edit folder elements

You can select a number of elements in the table, right-click and choose Edit to batch edit the elements. In this way, you can change for example the description or name of several elements in one go.

In figure 3.8 you can see an example where the name of two sequences are renamed in one go. In this example, a dialog with a text field will be shown, letting you enter a new name for these two sequences.

**Note!** This information is directly saved and you cannot undo.

Drag and drop folder elements

You can drag and drop objects from the folder editor to the Navigation area. This will create a copy of the objects at the selected destination. New elements can be included in the folder editor in the view area by dragging and dropping an element from a destination in the Navigation Area to the folder in the Navigation Area that you have open in the view area. It is not possible to drag elements directly from the Navigation Area to the folder editor in the View area.
3.2 Metadata

Metadata refers to information about data. In the context of the CLC Workbenches, this will usually mean information about samples. For example a set of reads could come from a particular specimen at a particular time point with particular characteristics. The specimen, time and characteristics would be metadata for that set of reads. The data can then be associated with its metadata in the Workbench. This can be useful for keeping track of related datasets and metadata can be used by some types of analyses in some CLC Workbenches.

Metadata can be created directly in the Workbench, but typically it will be imported from an external file (excel or text based). See section 3.2.1. It is then stored as a metadata table in the Workbench. An example of a metadata table as it might appear in the Workbench is shown in figure 3.9.

![Figure 3.9: A simple Metadata Table.](image)

Each column represents a property of a sample (e.g. identifier, height, age, treatment, etc.) and each row contain information relevant to a sample.

Within the CLC Workbench, one of the metadata table columns may be designated as the key column. The entries in a key column must be unique. Any column can be chosen to be the key column, but commonly it will be the first column and it would contain an identifier of some sort (e.g. a name).

There are no restrictions on the type of information that can be held in a metadata table. However, it is generally recommended that any given metadata table contains information about a related collection of entities. For example, a set of samples from the same experiment, or a set of families from the same study. Any particular data element can only be associated with at most one row in a given metadata table. However, that same data element can be associated with metadata in other metadata tables.

During or after metadata import, data can be associated with that metadata. Once a data element is associated with metadata, the outputs of analyses involving that data usually inherit the metadata association automatically. Inheritance like this is carried out when the metadata association for the outputs can be unambiguously identified. So, for example, if an output is derived from two inputs with different metadata associations, then neither association will be inherited by the output data elements.

Importing metadata can be done using a basic or advanced tool, and viewing and working with metadata, including data association, is done using the Metadata Table editor.
3.2.1 Importing Metadata

There are two tools that can be used to import metadata, one basic and one more advanced. A list of the benefits and limitations of each is included at the start the sections describing them.

The basic import tool is fast and easy, but less flexible than the advanced metadata import using the Metadata Table Editor. General features of this importer are:

- Excel (.xlsx/.xls) format files are imported.
- The first column in the Excel file must have unique entries. That column is designated the key column.
- Optionally, data elements can have associations to the metadata made.
- Metadata association using this tool matches data element names with the entries in the first column of the metadata being imported. Name matching can be based on exact or partial matches.
- Data elements that will be associated to metadata being imported are listed in a preview window.
- All columns are imported as text columns.

If desired, a metadata table can be edited later from within the Metadata Table editor as described in section 3.2.3. There, you can change the column data types (e.g. to types of numbers, dates, true/false) and you can designate a new key column.

To run the basic importer, go to:

File | Import | Import Metadata

In the box labeled Spreadsheet with sample information, select the Excel file (.xlsx/.xls) to be imported.

The rows in the spreadsheet are displayed in the Metadata preview window, as shown in figure 3.10. Click Next.

![Image of Metadata preview window]

Figure 3.10: After an Excel file is selected, its rows are visible in the Metadata preview table.

The second wizard step, called "Associate with data", is optional. To proceed without associating data to metadata, click on the the button labeled Next.
Associating data with the metadata being imported is illustrated in figure 3.11. To do this:

- In the field labeled **Location of data**, click on the folder icon to the right and select the data elements of interest.
- In the Matching scheme section, select whether data element names must match exactly the entries in the first column of the metadata to have an association created (Exact), or whether partial matches are allowed (Partial). The two matching schemes are described in detail in section 3.2.3.

The Data association preview area shows data elements that will have associations created, along with information from the metadata row they are being linked with. This gives the opportunity to check that the matching is leading to the expected links between data and metadata.

![Figure 3.11: Three data elements were selected for association with 8 metadata rows. All three will have an associated added. Here, the partial matching scheme has been selected.](image)

- Click on the button labeled **Next**.
- Select where you wish the metadata table to be saved.
- Click on the button labeled **Finish**.

The associated information can be viewed for a given data element in the Show Element Info view, as show in figure 3.12.

### 3.2.2 Advanced Metadata Import

If the information about the data is in an excel file and the entries in the first column are unique, then the Import Metadata tool described in section 3.2.1 can be used to define the table and import the metadata in a couple of steps.

In other cases, the **Metadata Table Editor** can be used to import metadata from an external file, or to create and populate a metadata table directly. It involves more steps than the basic import tool, but is more flexible and has some basic error checking associated with data types. General features of this importer are:
Figure 3.12: Metadata associations can be seen, edited, refreshed or deleted via the Show Element Info view.

- Can import from Excel (.xlsx/.xls) or text files with a common delimiter can be used.
- The structure of the metadata table (the columns, their type, and the key column) must be set up before the metadata (contents) are imported.
- It is generally recommended that one column be designated as the key column. Entries in that column must have unique entries.
- The default data type for columns on creation is text, but this can be altered before import commences. When importing the metadata, an error will result if entries are found that do not match the expected data type.
- Association with metadata is done by matching data element names with the entries in the first column of the spreadsheet. Name matching can be based on exact or partial matches.
- Association of data with metadata is done as a separate step from import, providing flexibility. For example, if information in more than one column together uniquely identifies a sample, but the information within a single given column does not uniquely do so.
- Association of data with metadata can be done row by row if key column entries and the names of the relevant data elements are not related.

To start the Metadata Table Editor, go to:

File | New | Metadata Table

This opens a new metadata table with no columns and no rows. Importing metadata using the Metadata Table Editor requires that the table structure is defined first.

**Defining the table structure**

Click on the button labeled Setup Table at the bottom of the view (figure 3.13).

To create a metadata table from scratch, use the "Add column right" or "Add column left" buttons to define the table structure with the amount of columns you will need, and edit the fields of each column as needed.
To import the table from a file, click on **Setup Structure from File**. In the dialog that appears (figure 3.14), you need to provide the following information:

- **Filename** The EXCEL or delimited TEXT file to import. Column names should be in the first row of this file.
- **Encoding** For text files only: the encoding used to create the file. The default is UTF-8.
- **Separator** For text files only: The character used to separate the columns. The default is semicolon (;).

For each column in the external file, a column will be created in the new metadata table. By default the type of these imported columns is "Text". You will see a reminder to set the column type for each column and to designate one of the columns as the key column.

Edit the following information for each column:

- **Name**. A mandatory header name or title for the column.
- **Description**. An optional description of the information that will be held in the column. The description will appear as a tool tip, visible when you hover the mouse cursor over the column name in the metadata table.
• **Key column.** Put a check in the box in the one column that will be the "key" column. All rows in this column must be populated and all entries in this column must be unique.

• **Type.** The type of value allowed. The available types are:
  
  - **Text** Simple text.
  - **Whole number** Integer values, like 42 or -7.
  - **Decimal number** Decimal values, like 3.14 or 1.72e13.
  - **Yes / No** Yes/No or True/False values are accepted. Capitalization is not necessary.
  - **Date** Local dates such as 2015-04-23 for April 23rd, 2015.
  - **Date and time** Local date and time such as 2015-04-23 13:37 for 1:37pm on April 23rd, 2015. Note the use of 24-hour clock and that no time zone information is present.

Navigate between the columns using the (_prev) Prev and (_next) Next buttons, or by using left/right arrow keys with Alt key held down.

Modifications made to a particular column take effect as you navigate to another column, or if you close the dialog using **Done**.

The (undo) and (redo) buttons are used undo and redo changes respectively. When the columns have been configured, click on the button labeled **Done**.

Columns may be deleted using the (delete) button. After metadata has been imported, additional columns can be added to the table structure. This can be done by importing the altered structure from an external file, where any columns not already in the metadata table will be added. Alternatively, individual columns can be added using the (insert before) and (insert after) buttons, which insert new columns before and after the current column respectively.

**Populating the table**

Click on **Manage Data** button at the bottom of the view (figure 3.15).

The metadata table can then be populated by editing each column manually. Row information is added manually by clicking on the (add row) button and typing in the information for each column.

It is also possible to import information from an external file. In that case, the column names in the metadata table in the workbench will be matched with those in the external file to determine which values go into which cell. Only cell values in columns with an exact name match will be imported. If the file used contains columns not in the metadata table, the values in those columns will be ignored. Conversely, if the metadata table contains columns not present in the file, imported rows will have no values for those columns.

Click on **Import Rows from File** and select the external file of metadata. This brings up the window shown in figure 3.16.

When working with an existing metadata table and adding extra rows, it is generally recommended that a key column be designated first. If a key column is not present, then all rows in the file will be imported. With no key column designated, if any rows from that file were imported into the same metadata table earlier, a duplicate row will be created. With a key column, rows with
a new, unique entry for that column are added to the table and existing rows with a key entry in the file will be updated, incorporating any changes present in the file. Duplicate rows will not be created.

The options presented in the Import Metadata Rows into Metadata Table are:

- **File.** The file containing the metadata to import. This can be Excel (.xlsx/.xls) format or a delimited text file.

- **Encoding.** For text files only: The text encoding of the selected file. Specifying the correct encoding is important to ensure that the file is correctly interpreted.

- **Separator.** For text files only: the character used to separate columns in the file.

- **Locale.** For text files only: the locale used to format numbers and dates within the file.

- **Date format.** For text files only: the date format used in the imported file.
**Date-time format.** For text files only: the date-time format used in the imported file. The date and date-time templates uses the Java patterns for date and time formatting. Meaning of some of the symbols:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Meaning</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>y</td>
<td>Year</td>
<td>2004; 04</td>
</tr>
<tr>
<td>d</td>
<td>Day</td>
<td>10</td>

</tr>
</tbody>
</table>

With a short year format (YY), 2000 will be added when imported as, or converted to, Date or Date and time format. Thus, when working with dates before the year 2000 or after 2099, please use a four digit format for the year (YYYY).

Click the button labeled **Finish** button when the necessary fields have been filled in.

The progress and status of the row import can be seen in the Processes tab of the Toolbox. Any errors resulting from an import that failed can be reviewed here. The most frequent errors are associated with selecting the wrong separator or encoding, or wrong date/time formats when importing rows from delimited text files.

Once the rows are imported, The metadata table can be saved.

### 3.2.3 Associating data elements with metadata

Typically, one would use the tools described in this section to associate data elements with metadata just after the data has been imported. Doing this at this early stage means that analysis results generated using these inputs will often inherit the metadata association. This inheritance is done when the relevant association can be determined unambiguously.

Each association between a particular data element and a row in your Metadata Table will have a "role" label that indicates what the role of the data element has. For example, a newly import sequence list could be given a role like "Sample data", or "NGS reads". Each analysis tool provides a particular role label when applying a metadata association to the outputs it generates. For example, a read mapping tool could assign the role "Un-mapped reads" to a sequence list of unmapped reads that it produces. When viewing all the data associated with a given metadata entry, these roles can help distinguish the particular data elements of interest.
The metadata table must be saved before data association options are available to use.

To associate data elements with the rows of a Metadata Table, click the **Associate Data** button at the bottom of the Metadata Table view. When an metadata association is created for, or removed from, a data element, this change to the data element is automatically saved.

If a key column has been identified for the metadata table, two options will be available:

- **Association Data Automatically**: The whole metadata table is used and associations between the selected data elements and the metadata are applied based on matching of the element name with the key column entries in the metadata table.
- **Associate Data with Row**: You select a row of the metadata and a particular data element and an association is then created. Information in the metadata table does not need to match the name of the data elements using this option. This option is also available when right-clicking a row in the table.

Each of these has benefits and restrictions. These are described at the top of each sections describing these options.

**Associate Data Automatically**

The main characteristics of the **Associate Data Automatically** tool are:

- Suited to associated large metadata tables or associating to many data elements.
- Well suited for use with newly imported data, where no associations already exist.
- Associations are created based on matching the information in the key column of the metadata table with the name of the selected data elements.
- Two matching schemes are available: Exact and Partial (see section 3.2.3).
- A key column must be identified for the metadata table for this option to be available.
- Use with care with data elements that already have associations with the metadata table being worked with. As well as adding any new associations, existing associations will be updated to reflect the current information in the metadata table. This means associations will be deleted for a selected data element if there are no rows in the metadata table that match the name of that data element. See also the warning at the end of this section about this.

To run the **Associate Data Automatically** tool, click the **Associate Data** button at the bottom of the Metadata Table view, and select **Associate Data Automatically**.

Your metadata table must be saved and a key column designated for the metadata table for this option to be available.

Select the data the tool should consider when setting up metadata associations in the window that appears. An example of this is shown in figure 3.17. You can select an item or sets of items in the navigation area on the left and move these into the selected elements list. Alternatively, you can right click on a folder and specify that all elements in the folder should be put in the selected elements list. This is illustrated in figure 3.18.
Specify a role that should be assigned to each data element that is associated to a metadata row (figure 3.19). The role can be anything that describes the data element best.

Select whether the matching of the data element names to the entries in the key column should be based on exact or partial matching. These options are explained further below.

Choose to Save the outputs. Data associations and roles will be saved for data elements where the name matches a key column entry according to the selected matching scheme.

Warning: It is safest only to select data elements that have no existing association to the metadata table being worked with, or carefully selecting any data elements with an existing association which you wish to update. All data selected that has an association with the
metadata table being worked with will be *updated* by the automatic association tool. This means that any new or updated information in a metadata row can be added, but it also means that if no rows in the metadata match such a data element anymore, then the data association will be removed. This could happen if, for example, you changed the name of a data element with a metadata association, and did not change the corresponding key entry in the metadata table.

**Matching schemes** A data element name must match an entry in the key column of a metadata table for an association to be set up between that data element at the corresponding row of the metadata table. Two schemes are available in the *Association Data Automatically* for matching up names with key entries:

- **Exact** - data element names must match a key exactly to be associated. If any aspect of the key entry differs from the name of a selected data element, no association will be created.
- **Partial** - data elements with names partially matching a key will be associated. Here, data element names are broken into parts using common delimiters. The first whole part(s) must match a key entry in the metadata table for an association to be established. This option is explained in more detail below.

**Partial matching rules** For each data element being considered, the partial matching scheme involves breaking a data element name into components and searching for the best match from the key entries in the metadata table. In general terms, the best match means the longest key that matches entire components of the name.

The following describes the matching process in detail:

- **Break the data element name into its component parts based on the presence of delimiters.** It is these parts that are used for matching to the key entries of the metadata table. Delimiters are any non-alphanumeric characters. That is, anything that is not a letter (a-z or A-Z) or number (0-9). So, for example, characters like hyphens (-), plus symbols (+), spaces, brackets, and so on, would be used as delimiters.

  If partial matching was chosen with a data element called *Sample234-1 (mapped) (trimmed)* would be split into 4 parts: *Sample234, -1, (mapped) and (trimmed)*.

- **Matches are made at the component level.** A whole key entry must match perfectly to at least the first complete component of a data element name.

  For example, a key entry *Sample234* would be a match to the data element with name *Sample234-1 (mapped) (trimmed)* because the whole key entry matches the whole of the first component of the data element name. Conversely, if they key entry had been *Sample23*, no match would be identified, because they whole key entry does not match to at least the whole of the first component of the data element name.

  In cases where a data element could be matched to more than one key, the longest key matched determines the metadata row the data will be associated with.

The table below provides examples to illustrate the partial matching system, on a table that has the keys with sample IDs like in figure [3.21](i.e. ETC-001, ETC-002, ..., ETC-013),
### Associate Data with Row

The main characteristics of the **Associate Data with Row** tool are:

- Suited for association of a few metadata tables to a few data elements.
- Full control to select which data element should be associated with a particular metadata row.
- No requirement for a key column in the metadata table.
- No requirement for a relationship between the name of the data element and the metadata to associate it with.

To associate data elements with a particular row in the metadata table:

- Select the desired row in the metadata table by clicking on it.
- Right click and select the **Associate Data with Row** option (see figure 3.21), or click on the **Associate Data** button at the bottom of the view and choose the option **Associate Data with Row**.

![Figure 3.21: Manual association of data elements to a metadata row.](image)

- A window will open within which you can select the data elements that should have an association with the metadata row.

If a selected data element already has an association with this particular metadata table, that association will be updated. Associations with any other metadata tables will be left as they are.
• Click **Next**.

• Enter a role for the data elements that have been chosen and click **Next** until you can choose to **Save** the outputs.

Data associations and roles will be saved for the selected data elements.

### 3.2.4 Working with data and metadata

#### Finding data elements based on metadata

Using the Metadata Table view you can find data elements associated with rows of the metadata table. From this view, it is possible to launch analyses on selected data.

To find data elements associated with selected metadata rows:

• Select one or more rows of interest in the metadata table.

• Click on the button labeled **Find Associated Data** at the bottom of the view.

A table with a listing of the data elements associated to the selected metadata row(s) will appear (figure 3.22).

![Figure 3.22: Metadata Table with search results](image)

The search results table shows the type, name, and navigation area path for each data element found. It also shows the key entry of the metadata table row with which the element is associated and the role of the data element for this metadata association. In figure 3.22, there are five data elements associated with sample ETC-009. Three are Sequence Lists, two of which have a role that tells us that they are un-mapped reads resulting from the Map Reads to Reference tool.

Clicking the **Refresh** button will re-run the search and refresh the search results table.
Click the button labeled Close to close the search table view.

Data elements listed in the search result table can be opened by clicking on the button labeled Show at the bottom of the view.

Alternatively, they can be highlighted in the Navigation Area by clicking the Find in Navigation Area button.

Analyses can be launched on the selected data elements:

- Directly. Right-click on one of the selected elements, choose the menu option Toolbox, and navigate to the tool of interest. The data selected in the search results table will be listed as selected elements in the Wizard that appears.

- Via the Navigation area selection. Use the Find in Navigation Area button and then launch a tool in the Toolbox. The items that were selected in the Navigation area will be pre-selected in the Wizard that is launched.

If no data elements with associations are found and this is unexpected, please re-index the locations your data are stored in. This is described in section 3.5. For data held in a CLC Server location, an administrator will need to run the re-indexing. Information on this can be found in the CLC Server admin manual at http://resources.qiagenbioinformatics.com/manuals/clcserver/current/admin/index.php?manual=Rebuilding_index.html.

Identifying metadata rows without associated data

Using the Metadata Table view you can apply filters using the standard filtering tools shown at the top of the view as well as by using special metadata filtering in the Additional Filtering shown at the bottom. Using the special metadata filtering option Show only Unassociated Rows, you can filter the rows visible in the Metadata Table view so only the rows to which no data elements are associated are shown. If desired, these rows could then be used to launch one of the tools for associating data, described in section 3.2.3.

This filter can be cancelled by clicking on the Additional Filtering button again and clicking on the Show only Unassociated Rows again. When the filter is active, it has a checkmark beside it. When it is inactive, it does not.

This filter can take a long time if many rows are shown in the table. When working with many rows, it can help if the full table is filtered using the general filters in advance, using the standard filters at the top of the table view. Alternatively you can pre-select some rows and filtering with the Additional filtering option Filter to Selected Rows. This filter can be applied multiple times. If the search takes too long, you can cancel it by unselecting the filter from the menu.

This filter can be cancelled by clicking on the Additional Filtering button again and clicking on the Clear Selection Filter option.

Viewing metadata associations

Metadata associations for a data element are shown using the Element info view, as in figure 3.23.

To show Element Info,
right-click an element in the Navigation Area | Show | Element Info (лиз)

![Element Info view with a metadata association](image)

**Figure 3.23: Element Info view with a metadata association**

The Element Info view contains the details of each metadata association for the data element. The following operations are available:

- **Delete** will remove an association.
- **Edit** will allow you to change the role of the metadata association.
- **Refresh** will reload the metadata details from the Metadata Table; this functionality may be used to attempt to re-fetch metadata that was previously unavailable, e.g. due to server connectivity.

Read more about Element Info view in section 11.4.

**Removing metadata associations**

Any or all associations to data elements from rows of a metadata table can be removed by taking the following steps:

1. Open the metadata table containing the rows of interest.
2. Highlight the relevant rows of the metadata table.
3. Click on the button labeled Find Associated Data.
4. In the Metadata Elements table that opens, highlight the rows for the data elements the metadata associations should be removed from.
5. Right click over the highlighted area and choose the option Remove Association(s) (figure 3.24). Alternatively, use the Delete key on the keyboard, or on a Mac, the fn and backspace keys at the same time.

Metadata associations can also be removed from within the Element info view for individual data elements, as described in section 3.2.4.

When an metadata association is removed from a data element, this update to the data element is automatically saved.
Exporting metadata

The standard Workbench export functionality can be used to export metadata tables to various formats. The system’s default locale will be used for the export, which will affect the formatting of numbers and dates in the exported file.

See section 6.6 for more information.

3.3 Working with tables

Tables are used in a lot of places in the CLC Genomics Workbench. There are some general features for all tables, irrespective of their contents, that are described here.

Figure 3.25 shows an example of a typical table. This is the table result of Find Open Reading Frames. We use this table as an example to illustrate concepts relevant to all kinds of tables.

Table viewing options in the Side Panel

Options relevant to the view of the table can be configured in the Side Panel on the right.
The Column width can be set to **Automatic** or **Manual**. By default, the first time you open a table, it will be set to **Automatic**. The default selected columns are hereby resized to fit the width of the viewing area. When changing to the **Manual** option, column widths will adjust to the actual header size, and each column size can subsequently be adjusted manually. When the table content exceeds the size of the viewing area, a horizontal scroll becomes available for navigation across the columns.

You can choose which columns can be displayed in the table by checking them in or out from the Side Panel. In some tables, a single checkbox can be used to hide or show a whole set of columns belonging to a certain category. Two buttons called **Select all** and **Deselect all** allow you to select or deselect all columns from that Side Panel section in one click.

Finally, in some table (such as Expression Browser), the content of some columns can be modified using the settings from the Side Panel (such as Expression values and Grouping in figure 3.26).

![Figure 3.26: A table showing the results of an RNA-seq analysis.](image)

**Sorting tables**

You can **sort** table according to the values of a particular column by clicking a column header. Clicking once will sort in ascending order. A second click will change the order to descending. A third click will set the order back its original order.

Pressing Ctrl - ` on Mac - while you click other columns will refine the existing sorting with the values of the additional columns, in the order in which you clicked them.

**3.3.1 Filtering tables**

The final concept to introduce is **Filtering**.

A button called **Filter to selection** allows for reducing the size of a table to a few pre-selected rows. The option **Filter to selected rows** will keep in the table view only the rows that are selected, whether they were selected manually, or by using the function "Select in other views" available for some tables (for example when the table is associated with a graphical view such as a Venn diagram, or a volcano plot). Restore the complete table by choosing the option **Clear selection filter**.
In the top right corner of a table view, a filter field can be used to filter a table as well. This table filter has an advanced and a simple mode.

The simple mode is the default and is applied simply by typing text or numbers (see an example in figure 3.27).

Typing "neg" in the filter will only show the rows where "neg" is part of the text in any of the columns. The text does not have to be in the beginning, thus "ega" would give the same result. This simple filter works fine for fast, textual and non-complicated filtering and searching. Filtering is automatic once you start typing, unless you are working with a table with more than 10000 rows, in which case you have to actually click the Filter button for the filtering to take effect.

In the advanced mode, you can make use of numerical information or make more complex filter combinations using more than one criterion in the filter. Click the Advanced filter button to open the first criterion of the advanced filter. Criteria can be added or removed by clicking the Add or Remove buttons. At the top, you can choose whether all the criteria should be fulfilled (Match all), or if just one of the needs to be fulfilled (Match any).

For each filter criterion, you first have to select which column it should apply to.

Next, you choose an operator. For numbers, you can choose between:

- = (equal to)
- < (smaller than)
- > (greater than)
- <> (not equal to)
- abs. value < (absolute value smaller than. This is useful if it doesn’t matter whether the number is negative or positive)
- abs. value > (absolute value greater than. This is useful if it doesn’t matter whether the number is negative or positive)

Note, that the number of digits displayed is a formatting option which can be set in the View Preferences. The true number may well be (slightly) larger. This behaviour can lead to problems when filtering on exact matches using the = (equal to) operator on numbers. Instead, users are advised to use two filters of inequalities (< (smaller than) and > (greater than)) delimiting a (small) interval around the target value.

For text-based columns, you can choose between:
• **starts with** (the text starts with your search term)

• **contains** (the text does not have to be in the beginning)

• **doesn’t contain**

• **=** (the whole text in the table cell has to match, also lower/upper case)

• **≠** (the text in the table cell has to not match)

• **is in list** (The text in the table cell has to match one of the items of the list. Items are separated by comma, semicolon, or space. This filter is not case-sensitive.)

• **is not in list** (The text in the table cell must not match any of the items of the list. Items are separated by comma, semicolon, or space. This filter is not case-sensitive)

Once you have chosen an operator, you can enter the **text or numerical value** to use.

The advanced filter criterion mentioned above are also available from a menu that appears by right-clicking on a value in a table: just specify the operator, and the column and value where you right-clicked for the menu to appear will define the two other fields of the advanced filter.

If you wish to reset the filter, simply remove (x) all the search criteria. Note that the last one will not disappear - it will be reset and allow you to start over.

Figure **3.28** shows an example of an advanced filter which displays the open reading frames larger than 400 that are placed on the negative strand.

![Figure 3.28: The advanced filter showing open reading frames larger than 400 that are placed on the negative strand.](image)

Both for the simple and the advanced filter, there is a counter at the upper left corner which tells you the number of rows that pass the filter (91 in figure **3.27** and 15 in figure **3.28**).

### 3.4 Customized attributes on data locations

Location-specific attributes can be set on all elements stored in a given data location. Attributes could be things like company-specific information such as LIMS id, freezer position etc. Attributes are set using a CLC Workbench acting as a client to the CLC Server.

Note that the attributes scheme belongs to a particular data location, so if there are multiple data locations, each will have its own set of attributes.
To configure which fields that should be available\(^1\) go to the Workbench:

right-click the data location | Location | Attribute Manager

This will display the dialog shown in figure 3.29.

Figure 3.29: Adding attributes.

Click the Add Attribute (➕) button to create a new attribute. This will display the dialog shown in figure 3.30.

Figure 3.30: The list of attribute types.

First, select what kind of attribute you wish to create. This affects the type of information that can be entered by the end users, and it also affects the way the data can be searched. The following types are available:

- **Checkbox.** This is used for attributes that are binary (e.g. true/false, checked/unchecked and yes/no).
- **Text.** For simple text with no constraints on what can be entered.
- **Hyper Link.** This can be used if the attribute is a reference to a web page. A value of this type will appear to the end user as a hyper link that can be clicked. Note that this attribute can only contain one hyper link. If you need more, you will have to create additional attributes.
- **List.** Lets you define a list of items that can be selected (explained in further detail below).

\(^1\)If the data location is a server location, you need to be a server administrator to do this.
• **Number.** Any positive or negative integer.

• **Bounded number.** Same as number, but you can define the minimum and maximum values that should be accepted. If you designate some kind of ID to your sequences, you can use the bounded number to define that it should be at least 1 and max 99999 if that is the range of your IDs.

• **Decimal number.** Same as number, but it will also accept decimal numbers.

• **Bounded decimal number.** Same as bounded number, but it will also accept decimal numbers.

When you click **OK**, the attribute will appear in the list to the left. Clicking the attribute will allow you to see information on its type in the panel to the right.

Lists are a little special, since you have to define the items in the list. When you choose to add the list attribute in the left side of the dialog, you can define the items of the list in the panel to the right by clicking **Add Item** (see figure 3.31).

![Figure 3.31: Defining items in a list.](image)

Remove items in the list by pressing **Remove Item**.

**Removing attributes** To remove an attribute, select the attribute in the list and click **Remove Attribute**. This can be done without any further implications if the attribute has just been created, but if you remove an attribute where values have already been given for elements in the data location, it will have implications for these elements: The values will not be removed, but they will become static, which means that they cannot be edited anymore.

If you accidentally removed an attribute and wish to restore it, this can be done by creating a new attribute of exactly the same name and type as the one you removed. All the "static" values will now become editable again.

When you remove an attribute, it will no longer be possible to search for it, even if there is "static" information on elements in the data location.

Renaming and changing the type of an attribute is not possible - you will have to create a new one.
Changing the order of the attributes  You can change the order of the attributes by selecting an attribute and click the **Up** and **Down** arrows in the dialog. This will affect the way the attributes are presented for the user.

**3.4.1 Filling in values**

When a set of attributes has been created (as shown in figure 3.32), the end users can start filling in information.

![A set of attributes defined in the attribute manager.](image)

Figure 3.32: A set of attributes defined in the attribute manager.

This is done in the element info view:

right-click a sequence or another element in the Navigation Area | Show ( ) | Element info ( )

This will open a view similar to the one shown in figure 3.33.

![Adding values to the attributes.](image)

Figure 3.33: Adding values to the attributes.

You can now enter the appropriate information and **Save**. When you have saved the information, you will be able to search for it (see below).

Note that the element (e.g. sequence) needs to be saved in the data location before you can edit
the attribute values.

When nobody has entered information, the attribute will have a "Not set" written in red next to the attribute (see figure 3.34).

![Figure 3.34: An attribute which has not been set.](image)

This is particularly useful for attribute types like checkboxes and lists where you cannot tell, from the displayed value, if it has been set or not. Note that when an attribute has not been set, you cannot search for it, even if it looks like it has a value. In figure 3.34, you will not be able to find this sequence if you search for research projects with the value "Cancer project", because it has not been set. To set it, simply click in the list and you will see the red "Not set" disappear.

If you wish to reset the information that has been entered for an attribute, press "Clear" (written in blue next to the attribute). This will return it to the "Not set" state.

The Folder editor, invoked by pressing Show on a given folder from the context menu, provides a quick way of changing the attributes of many elements in one go (see section 3.1.8).

### 3.4.2 What happens when a clc object is copied to another data location?

The user supplied information, which has been entered in the Element info, is attached to the attributes that have been defined in this particular data location. If you copy the sequence to another data location or to a data location containing another attribute set, the information will become fixed, meaning that it is no longer editable and cannot be searched for. Note that attributes that were "Not set" will disappear when you copy data to another location.

If the element (e.g. sequence) is moved back to the original data location, the information will again be editable and searchable.

If the e.g. Molecule Project or Molecule Table is moved back to the original data location, the information will again be editable and searchable.

### 3.4.3 Searching

When an attribute has been created, it will automatically be available for searching. This means that in the Local Search, you can select the attribute in the list of search criteria (see figure 3.35).

![Figure 3.35: The attributes from figure 3.32 are now listed in the search filter.](image)
It will also be available in the **Quick Search** below the **Navigation Area** (press Shift+F1 (Fn+Shift+F1 on Mac) and it will be listed - see figure 3.36).

![Quick Search](image)

Figure 3.36: The attributes from figure 3.32 are now available in the Quick Search as well.

### 3.5 Local search

There are two ways of doing text-based searches of your data, as described in this section:

- **Quick-search** directly from the search field in the **Navigation Area**.
- **Advanced search** which makes it easy to make more specific searches.

In most cases, quick-search will find what you need, but if you need to be more specific in your search criteria, the advanced search is preferable.

**What kind of information can be searched?** Below is a list of the different kinds of information that you can search for (applies to both quick-search and the advanced search).

- **Name.** The name of a sequence, an alignment or any other kind of element. The name is what is displayed in the **Navigation Area** per default.
- **Length.** The length of the sequence.
- **Organism.** Sequences which contain information about organism can be searched. In this way, you could search for e.g. *Homo sapiens* sequences.
- **Custom attributes.** Read more in section 3.4

Only the first item in the list, **Name**, is available for all kinds of data. The rest is only relevant for sequences.

If you wish to perform a search for sequence similarity, use Local BLAST (see section 12.1.2) instead.
Search index  This section has a technical focus and is not relevant if your searches are working well.

However, if you experience problems with your search results, i.e., if you do not get the hits you expect, it might be because of an index error.

The CLC Genomics Workbench automatically maintains an index of all data in all locations in the Navigation Area. If this index becomes out of sync with the data, you will experience problems with strange results. In this case, you can rebuild the index:

Right-click the relevant location | Location | Rebuild Index

This will take a while depending on the size of your data. At any time, the process can be stopped in the process area, see section 2.3.1.

3.5.1 Quick search

At the bottom of the Navigation Area there is a text field as shown in figure 3.37). To search, simply enter a text to search for and press Enter.

![Figure 3.37: Search simply by typing in the text field and press Enter.](image)

Note that the search term supports advanced features known from web search engines, which means that the following list of characters carry special meaning: + - && || ! ( )  ~* ? : \. To avoid this special interpretation it is suggested to put quotes around the search expression when searching for data containing the special characters, or read the section 3.5.2 on advanced search expressions.

To show the results, the search pane is expanded. If there are many hits, only the 50 first hits are immediately shown. At the bottom of the pane you can click Next to see the next 50 hits. In the preferences (see Chapter 4), you can specify the number of hits to be shown.

If a search gives no hits, you will be asked if you wish to search for matches that start with your search term. If you accept this, an asterisk (*) will be appended to the search term.
CHAPTER 3. DATA MANAGEMENT AND SEARCH

98

Pressing the Alt key while you click a search result will highlight the search hit in its folder in the Navigation Area.

**Search for data locations** The search function can also be used to search for a specific URL. This can be useful if you work on a server and wish to share a data location with another user. A simple example is shown in figure 3.38. Right click on the object name in the Navigation Area (in this case ATP8a1 genomic sequence) and select "Copy". When you use the paste function in a destination outside the Workbench (e.g. in a text editor or in an email), the data location will become visible. The URL can now be used in the search field in the Workbench to locate the object.

![Figure 3.38: The search field can also be used to search for data locations.](image)

**Quick search history** You can access the 10 most recent searches by clicking the icon (Q) next to the search field (see figure 3.39).

![Figure 3.39: Recent searches.](image)

Clicking one of the recent searches will conduct the search again.

**Special search expressions**

When you write a search term in the search field, you can get help to write a more advanced search expression by pressing *Shift+F1*. This will reveal a list of guides as shown in figure 3.40.

You can select any of the guides (using mouse or keyboard arrows), and start typing. If you e.g. wish to search for sequences named BRCA1, select "Name search (name:)", and type "BRCA1". Your search expression will now look like this: "name:BRCA1".

The guides available are these:
**Wildcard search (**)**. Appending an asterisk * to the search term will find matches starting with the term. E.g. searching for "brca*" will find both brca1 and brca2.

**Search related words (~)**. If you don’t know the exact spelling of a word, you can append a tilde to the search term. E.g. "brca1~" will find sequences with a brca1 gene.

**Include both terms (AND)**. If you write two search terms, you can define if your results have to match both search terms by combining them with AND. E.g. search for "brca1 AND human" will find sequences where both terms are present.

**Include either term (OR)**. If you write two search terms, you can define that your results have to match either of the search terms by combining them with OR. E.g. search for "brca1 OR brca2" will find sequences where either of the terms is present.

**Do not include term (NOT)** If you write a term after not, then elements with these terms will not be returned.

**Name search (name:)**. Search only the name of element.

**Organism search (organism:)**. For sequences, you can specify the organism to search for. This will look in the "Latin name" field which is seen in the Sequence Info view (see section 11.4).

**Length search (length:[START TO END])**. Search for sequences of a specific length. E.g. search for sequences between 1000 and 2000 residues: "length:1000 TO 2000".

**Note!** If you have added attributes (see section 3.4), these will also appear on the list when pressing Shift+F1.

If you do not use this special syntax, you will automatically search for both name, description, organism, etc., and search terms will be combined as if you had put OR between them.

### 3.5.2 Advanced search

As a supplement to the Quick search described in the previous section you can use the more advanced search:

- Edit | Local Search ( )
- or  Ctrl + Shift + F ( + Shift + F on Mac)
Figure 3.41: An example of searching for elements with the name, description and organism information that includes "ATP8" but do not include the term "mRNA".

The first thing you can choose is which location should be searched. All the active locations are shown in this list. You can also choose to search all locations. Read more about locations in section 3.1.1.

Furthermore, you can specify what kind of elements should be searched:

- All sequences
- Nucleotide sequences
- Protein sequences
- All data

When searching for sequences, you will also get alignments, sequence lists etc as result, if they contain a sequence which match the search criteria.

Below are the search criteria. First, select a relevant search filter in the Add filter: list. For sequences you can search for

- Name
- Length
- Organism

See section 3.5.1 for more information on individual search terms.

For all other data, you can only search for name.

If you use Any field, it will search all of the above plus the following:
CHAPTER 3. DATA MANAGEMENT AND SEARCH

- Description
- Keywords
- Common name
- Taxonomy name

To see this information for a sequence, switch to the **Element Info** view (see section 11.4). For each search line, you can choose if you want the exact term by selecting "is equal to" or if you only enter the start of the term you wish to find (select "begins with").

An example is shown in figure 3.42.

![Figure 3.42: Searching for Salmonella sequences larger than 1 million nucleotides.](image)

This example will find human nucleotide sequences (organism is *Homo sapiens*), and it will only find sequences shorter than 10,000 nucleotides.

Note that a search can be saved for later use. You do not save the search results - only the search parameters. This means that you can easily conduct the same search later on when your data has changed.
Chapter 4

User preferences and settings

Contents

4.1 General preferences .......................................................... 102
4.2 View preferences .............................................................. 104
  4.2.1 Import and export Side Panel settings ............................ 105
4.3 Data preferences .............................................................. 107
4.4 Advanced preferences ....................................................... 107
4.5 Export/import of preferences .............................................. 108
4.6 View settings for the Side Panel ......................................... 109

The first three sections in this chapter deal with the general preferences that can be set for CLC Genomics Workbench using the Preferences dialog. The next section explains how the settings in the Side Panel can be saved and applied to other views. Finally, you can learn how to import and export the preferences.

The Preferences dialog offers opportunities for changing the default settings for different features of the program.

The Preferences dialog is opened in one of the following ways and can be seen in figure 4.1:

  Edit | Preferences (Ctrl+Comma)
  or  Ctrl + K (⌘ + ; on Mac)

4.1 General preferences

The General preferences include:

- **Undo Limit.** As default the undo limit is set to 500. By writing a higher number in this field, more actions can be undone. Undo applies to all changes made on molecules, sequences, alignments or trees (see section 2.1.5).

- **Audit Support.** If this option is checked, all manual editing of sequences will be marked with an annotation on the sequence (see figure 4.2). Placing the mouse on the annotation will reveal additional details about the change made to the sequence (see figure 4.3). Note
CHAPTER 4. USER PREFERENCES AND SETTINGS

Figure 4.1: Preferences include General preferences, View preferences, Data preferences, and Advanced settings.

that no matter whether Audit Support is checked or not, all changes are also recorded in the History log (see section 2.1.2).

Figure 4.2: Annotations added when the sequence is edited.

Figure 4.3: Details of the editing.

- **Number of hits.** The number of hits shown in CLC Genomics Workbench, when e.g. searching NCBI. (The sequences shown in the program are not downloaded, until they are opened or dragged/saved into the Navigation Area).

- **Locale Setting.** Specify which country you are located in. This determines how punctuation is used in numbers all over the program.

- **Show Dialogs.** A lot of information dialogs have a checkbox: "Never show this dialog again". When you see a dialog and check this box in the dialog, the dialog will not be shown again. If you regret and wish to have the dialog displayed again, click the button in the General Preferences: Show Dialogs. Then all the dialogs will be shown again.

- **Usage information.** When this item is checked, anonymous information is shared with QIAGEN about how the Workbench is used. This option is enabled by default. The information shared with QIAGEN is:
  - Launch information (operating system, product, version, and memory available)
  - The names of the tools and workflows launched (but not the parameters or the data used)
Errors (but without any information that could lead to loss of privacy: file names and organisms will not be logged)

Installation and removal of plugins and modules

The following information is also sent:

- An installation ID. This allows us to group events coming from the same installation. It is not possible to connect this ID to personal or license information.
- A geographic location. This is predicted based on the IP-address. We do not store IP-addresses after location information has been extracted.
- A time stamp

### 4.2 View preferences

There are six groups of default View settings:

1. **Toolbar** lets you choose the size of the toolbar icons, and whether to display names below the icons (figure 4.4).

   ![Figure 4.4: Number formatting of tables.](image)

2. **Show Side Panel** allows you to choose whether to display the side panel when opening a new view. Note that for any open view, the side panel can be collapsed by clicking on the small triangle at the top left side of the settings area or by using the key combination Ctrl + U (⌘ + U on Mac).

3. **Number formatting in tables** specifies how the numbers should be formatted in tables (see figure 4.5). The examples below the text field are updated when you change the value so that you can see the effect. After you have changed the preference, you have to re-open your tables to see the effect.

4. **Sequence Representation** allows you to change the way the elements appear in the Navigation Area. The following text can be used to describe the element:

   - Name (this is the default information to be shown).
• Accession (sequences downloaded from databases like GenBank have an accession number).
• Latin name.
• Latin name (accession).
• Common name.
• Common name (accession).

5. **User Defined View Settings** gives you an overview of the different Side Panel settings that are saved for each view. See section 4.6 to learn more about how to create and save style sheets. If there are other settings beside CLC Standard Settings, you can use this overview to choose which of the settings should be used per default when you open a view (see an example in figure 4.6).

![Figure 4.5: Number formatting of tables.](image)

![Figure 4.6: Selecting the default view setting.](image)

Note that the content of this list depends on the nature of the elements that are saved in the Navigation Area. When the list grows, you may have to scroll up or down to find the relevant settings.

6. **Molecule Project 3D Editor** gives you the option to turn off the modern OpenGL rendering for **Molecule Projects** (see section 13.2).

### 4.2.1 Import and export Side Panel settings

If you have created a special set of settings in the **Side Panel** that you wish to share with other CLC users, you can export the settings in a file. The other user can then import the settings.

To export the **Side Panel** settings, first select the views that you wish to export settings for. Use Ctrl+click (⌘ + click on Mac) or Shift+click to select multiple views. Next click the **Export...** button.
that is situated below the list of possible settings (see figure 4.6), and not the Export button at the very bottom of the dialog, as this one will export the Preferences (see section 4.5).

A dialog will be shown (see figure 4.7) that allows you to select which of the settings you wish to export.

![Figure 4.7: Exporting all settings for circular views.](image)

When multiple views are selected for export, all the view settings for the views will be shown in the dialog. Click Export and you will now be able to define a save folder and name for the exported file. The settings are saved in a file with a .vsf extension (View Settings File).

Similarly, to import a Side Panel settings file, make sure you are at the bottom of the View panel of the Preferences dialog, and click the Import... button. Note that there is also another import button at the very bottom of the dialog, but this will import the other settings of the Preferences dialog (see section 4.5).

Select the *.vsf file where the settings are saved. The following dialog asks if you wish to overwrite existing Side Panel settings, or if you wish to merge the imported settings into the existing ones (see figure 4.8).

![Figure 4.8: When you import settings, you are asked if you wish to overwrite existing settings or if you wish to merge the new settings into the old ones.](image)

WARNING! If you choose to overwrite the existing settings, you will loose ALL the Side Panel settings that were previously saved.

To avoid confusion of the different import and export options, here is an overview:

- Import and export of **bioinformatics data** such as sequences, alignments etc. (described in section 6.1).
- **Graphics** export of the views which creates image files in various formats (described in
Import and export of Side Panel Settings as described above.

Import and export of all the Preferences except the Side Panel settings. This is described in the previous section.

4.3 Data preferences

The data preferences contain preferences related to interpretation of data:

- Multisite Gateway Cloning primer additions, a list of predefined primer additions for Gateway cloning (see section 19.4.1).
- Linkers for importing 454 data (see section 33.6).
- Linkers for importing Ion Torrent mate pair (see section 6.3.6)

4.4 Advanced preferences

Proxy Settings   The Advanced settings include the possibility to set up a proxy server. This is described in section 1.6.

Default data location   The default location is used when you import a file without selecting a folder or element in the Navigation Area first. It is set to the folder called CLC_Data in the Navigation Area, but can be changed to another data location using a drop down list of data locations already added (see section 3.1.1). Note that the default location cannot be removed, but only changed to another location.

Data Compression   CLC format data is stored in an internally compressed format. The application of internal compression can be disabled by unchecking the option "Save CLC data elements in a compressed format". This option is enabled by default. Turning this option off means that data created may be larger than it otherwise would be.

Enabling data compression may impose a performance penalty depending on the characteristics of the hardware used. However, this penalty is typically small, and we generally recommend that this option remains enabled.

Internal compression of CLC data was introduced in CLC Genomics Workbench 12.0, CLC Main Workbench 8.1 and CLC Genomics Server 11.0. CLC format files with internal compression are not compatible with older versions of the software. Turning this option off is likely to be of interest only at sites running a mix of older and newer CLC software, where the same data is accessed by different versions of the software.

To work with specific data sets in older CLC software versions, we recommend exporting the data to CLC or zip format and turning on the export option "Maximize compatibility with older CLC products". This is described in more detail in section 6.6.5.
NCBI Integration Without an API key, access to NCBI from a single IP-address is limited to 3 requests per second; if many workbenches use the same IP address when running the Search for Reads in SRA,..., Search for Sequences at NCBI, and Search for PDB Structures at NCBI tools they may hit this limit. In this case, you can create an API key for NCBI E-utils in your NCBI account and enter it here.

NCBI BLAST The standard URL for the BLAST server at NCBI is: https://blast.ncbi.nlm.nih.gov/Blast.cgi, but it is possible to specify an alternate server URL to use for BLAST searches. Be careful to specify a valid URL, otherwise BLAST will not work.

Read Mapper It is possible to change the size (in MB) of the Read Mapper reference cache.

SRA Download The following options are available:

- **Use Aspera when available** Per default, Aspera is automatically used if installed. This option makes it possible to disable Aspera.

- **Limit Aspera download speeds to [ ] Mb/s (Mac and Linux only)** Using Aspera may take up a lot of network resources. Use this option to specify a maximum download speed (in megabit per second). Note that this option is only available on Mac and Linux. For Windows users, it is possible to limit the maximum download speed by modifying the aspera.conf file, which can be found in C:\Program Files (x86)\Aspera\Aspera Connect\etc. See [http://download.asperasoft.com/download/docs/csrv/3.3.4/linux/html/index.html](http://download.asperasoft.com/download/docs/csrv/3.3.4/linux/html/index.html) and [http://download.asperasoft.com/download/docs/csrv/3.3.4/linux/html/fasp/setting-global-bandwidth.html](http://download.asperasoft.com/download/docs/csrv/3.3.4/linux/html/fasp/setting-global-bandwidth.html) for more details.

Reference Data It is possible to specify an alternate server URL to use for reference data. Reference data set available from the QIAGEN Sets tab in the Reference Data Manager is provided by QIAGEN, and the workbench is configured to download from QIAGEN by default. Unless you are in the special circumstance that your system administrator has decided to mirror this data locally and wishes you to use that mirror of the data, you should not change this setting.

You also have the option to choose to Download reference data to a CLC Server using the Server itself, or the Workbench. It is set by default to CLC Server, and should not be changed unless your system administrator recommends so.

CLC Server Login It is possible to Save the login username and password, initiate automatic server login when opening the workbench, and bypass a proxy server.

4.5 Export/import of preferences

The user preferences of the *CLC Genomics Workbench* can be exported to other users of the program, allowing other users to display data with the same preferences as yours. You can also use the export/import preferences function to backup your preferences.
To export preferences, open the Preferences dialog and click on the Export button at the bottom of the Preferences dialog. Select the relevant preferences and click Export to choose a location to save the exported file (see figure 4.9).

![Figure 4.9: Select which of the preferences you want to export.](image)

**Note!** The format of exported preferences is *.cpf*. This notation must be submitted to the name of the exported file in order for the exported file to work.

Before exporting, you are asked about which of the different settings you want to include in the exported file. One of the items in the list is "User Defined View Settings". If you export this, only the information about which of the settings is the default setting for each view is exported. If you wish to export the Side Panel Settings themselves, see section 4.2.1.

The process of importing preferences is similar to exporting: click the Import button and browse to the *.cpf* file.

To avoid confusion of the different import and export options, you can find an overview here:

- Import and export of bioinformatics data such as molecules, sequences, alignments etc. (described in section 6.1).
- Graphics export of the views that create image files in various formats (described in section 6.7).
- Import and export of Side Panel Settings as described in the next section.
- Import and export of all the Preferences except the Side Panel settings. This is described above.

### 4.6 View settings for the Side Panel

The Side Panel is shown to the right of all views that are opened in the View Area. Settings are specific to the type of view. Hence, when you save settings of a circular view, they will not be available if you open the sequence in a linear view (see section 2.1.8).
The options for saving and applying are available at the bottom of the Side Panel (see figure 4.10).

Opening a view type (e.g., a circular sequence, a variant table, or a PCA) for the first time will display the element using the CLC Standard Settings for that type of view. You can then adjust the settings using all the options available to you in the side panel. When you have adjusted a view to your preference, the new settings can be saved (see figure 4.11).

Saving can be done two ways. Write a name for the particular settings you just set, and choose to save:

- For that view alone, so that the settings will be available to you the next time you open this particular element. The settings are saved with only this element, and will be exported with the element if you later select to export the element to another destination.

- For all other views, when the option "Save for all element views" is checked, so that the settings will be available to you the next time you open any element for which this type of view is available.

Similarly, applying can be done two ways:

- For that view alone, so that the settings are applied the next time you open this particular element.
• For all other elements, when the option "Use as standard view settings for element view" is checked, so that the settings are applied each time you open any element for which this type of view is available. These "general" settings are user specific and will not be saved with or exported with the element.

"General" settings can be shared and imported with other workbench users using the Export and Import buttons at the bottom of the dialog. Exporting and importing saved settings can also be done in the Preferences dialog under the View tab (see section 4.2.1).

It is possible to remove a saved setting using the saved settings list from the drop-down menu and clicking Remove.
Chapter 5

Printing

Contents

5.1 Selecting which part of the view to print ........................................... 113
5.2 Page setup ......................................................................................... 114
5.3 Print preview .................................................................................... 116

CLC Genomics Workbench offers different choices of printing the result of your work.

This chapter deals with printing directly from CLC Genomics Workbench. Another option for using the graphical output of your work, is to export graphics (see chapter 6.7) in a graphic format, and then import it into a document or a presentation.

All the kinds of data that you can view in the View Area can be printed. The CLC Genomics Workbench uses a WYSIWYG principle: What You See Is What You Get. This means that you should use the options in the Side Panel to change how your data, e.g. a sequence, looks on the screen. When you print it, it will look exactly the same way on print as on the screen.

For some of the views, the layout will be slightly changed in order to be printer-friendly.

It is not possible to print elements directly from the Navigation Area. They must first be opened in a view in order to be printed. To print the contents of a view:

select relevant view | Print ( ) in the toolbar

This will show a print dialog (see figure 5.1).

In this dialog, you can:

- Select which part of the view you want to print.
- Adjust Page Setup.
- See a print Preview window.

These three options are described in the three following sections.
5.1 Selecting which part of the view to print

In the print dialog you can choose to:

- Print visible area, or
- Print whole view

These options are available for all views that can be zoomed in and out. In figure 5.2 is a view of a circular sequence which is zoomed in so that you can only see a part of it.

When selecting Print visible area, your print will reflect the part of the sequence that is visible in the view. The result from printing the view from figure 5.2 and choosing Print visible area can be seen in figure 5.3.

On the other hand, if you select Print whole view, you will get a result that looks like figure 5.4. This means that you also print the part of the sequence which is not visible when you have zoomed in.
5.2 Page setup

No matter whether you have chosen to print the visible area or the whole view, you can adjust page setup of the print. An example of this can be seen in figure 5.5.

In this dialog you can adjust both the setup of the pages and specify a header and a footer by clicking the tab at the top of the dialog.

You can modify the layout of the page using the following options:

- **Orientation**.
  - **Portrait**. Will print with the paper oriented vertically.
  - **Landscape**. Will print with the paper oriented horizontally.

- **Paper size**. Adjust the size to match the paper in your printer.
• **Fit to pages.** Can be used to control how the graphics should be split across pages (see figure 5.6 for an example).
  
  – **Horizontal pages.** If you set the value to e.g. 2, the printed content will be broken up horizontally and split across 2 pages. This is useful for sequences that are not wrapped
  
  – **Vertical pages.** If you set the value to e.g. 2, the printed content will be broken up vertically and split across 2 pages.

![Figure 5.5: Page Setup.](image1)

![Figure 5.6: An example where Fit to pages horizontally is set to 2, and Fit to pages vertically is set to 3.](image2)

**Note!** It is a good idea to consider adjusting view settings (e.g., **Wrap** for sequences), in the **Side Panel** before printing. As explained in the beginning of this chapter, the printed material will look like the view on the screen, and therefore these settings should also be considered when adjusting **Page Setup**.

**Header and footer**  Click the **Header/Footer** tab to edit the header and footer text. By clicking in the text field for either **Custom header text** or **Custom footer text** you can access the auto
formats for header/footer text in Insert a caret position. Click either Date, View name, or User name to include the auto format in the header/footer text.

Click OK when you have adjusted the Page Setup. The settings are saved so that you do not have to adjust them again next time you print. You can also change the Page Setup from the File menu.

5.3 Print preview

The preview is shown in figure 5.7.

The Print preview window lets you see the layout of the pages that are printed. Use the arrows in the toolbar to navigate between the pages. Click Print to show the print dialog, which lets you choose e.g. which pages to print.

The Print preview window is for preview only - the layout of the pages must be adjusted in the Page setup.

6.1 Standard import

CLC Genomics Workbench has support for a wide range of bioinformatic data such as molecules, sequences, alignments etc. See a full list of the data formats in section I.1.

These data can be imported through the Import dialog, using drag/drop or copy/paste as explained below.

For import of NGS data, please see section 6.3 For import of tracks, please see section 6.2.

Import using the import dialog

To start the import using the import dialog:

  click Import () in the Toolbar

and choose Standard Import

This will show a dialog similar to figure 6.1. You can change which kind of file types that should be shown by selecting a file format in the Files of type box.

Next, select one or more files or folders to import and click Next to select a place for saving the result files. If you import one or more folders, the contents of the folder is automatically imported and placed in that folder in the Navigation Area. If the folder contains subfolders, the whole folder structure is imported.
In the import dialog (figure 6.1), there are three import options:

**Automatic import** This will import the file and CLC Genomics Workbench will try to determine the format of the file. The format is determined based on the file extension (e.g. SwissProt files have .swp at the end of the file name) in combination with a detection of elements in the file that are specific to the individual file formats. If the file type is not recognized, it will be imported as an external file. In most cases, automatic import will yield a successful result, but if the import goes wrong, the next option can be helpful:

**Force import as type** This option should be used if CLC Genomics Workbench cannot successfully determine the file format. By forcing the import as a specific type, the automatic determination of the file format is bypassed, and the file is imported as the type specified.

**Force import as external file** This option should be used if a file is imported as a bioinformatics file when it should just have been external file. It could be an ordinary text file which is imported as a sequence.

**Import using drag and drop** It is also possible to drag a file from e.g. the desktop into the Navigation Area of CLC Genomics Workbench. This is equivalent to importing the file using the Automatic import option described above. If the file type is not recognized, it will be imported as an external file.

**Import using copy/paste of text** If you have e.g. a text file or a browser displaying a sequence in one of the formats that can be imported by CLC Genomics Workbench, there is a very easy way to get this sequence into the Navigation Area:

- Copy the text from the text file or browser
- Select a folder in the Navigation Area
- Paste

This will create a new sequence based on the text copied. This operation is equivalent to saving the text in a text file and importing it into the CLC Genomics Workbench.

If the sequence is not formatted, i.e. if you just have a text like this: "ATGACGAATAGGAGTTC-TAGCTA" you can also paste this into the Navigation Area.

**Note!** Make sure you copy all the relevant text - otherwise CLC Genomics Workbench might not be able to interpret the text.

### 6.1.1 External files

In order to help you organize your research projects, CLC Genomics Workbench lets you import all kinds of files. E.g. if you have Word, Excel or pdf-files related to your project, you can import them into the Navigation Area of CLC Genomics Workbench. Importing an external file creates a copy of the file which is stored at the location you have chosen for import. The file can now be opened by double-clicking the file in the Navigation Area. The file is opened using the default application for this file type (e.g. Microsoft Word for .doc-files and Adobe Reader for .pdf).

External files are imported and exported in the same way as bioinformatics files (see section 6.1). Bioinformatics files not recognized by CLC Genomics Workbench are also treated as external files.
There is a special tool for importing data from Vector NTI. This tool is a plugin which can be downloaded and installed in the *CLC Genomics Workbench* using the plugin manager (see section 1.5).

### 6.2 Import tracks

Tracks (see chapter 23) are imported in a special way, because extra information is needed in order to interpret the files correctly.

Tracks are imported using:  

**click Import (tı̄) in the Toolbar | Tracks**

This will open a dialog as shown in figure 6.2.

![Select files to import.](image)

At the top, you select the file type to import. Below, select the files to import. If import is performed with the batch option selected, then each file is processed independently and separate tracks are produced for each file. If the batch option is not selected, then variants for all files will be added to the same track (or tracks in the case VCF files including genotype information). The formats currently accepted are:

**FASTA**  This is the standard fasta importer that will produce a sequence track rather than a standard fasta sequence. Please note that this could also be achieved by importing using Standard Import (see section 6) and subsequently converting the sequence or sequence list to a track (see section 23.5).

**GFF2/GTF/GVF** A GFF2/GTF file does not contain any sequence information, it only contains a list of various types of annotations. A GVF file is similar to a GFF file but uses Sequence Ontology to describe genome variation data (see https://github.com/The-Sequence-Ontology/Specifications/blob/master/gvf.md). For these formats, the importer adds the annotation in each of the lines in the file to the chosen sequence, at the position or region in which the file specifies that it should go, and with the annotation type, name, description etc. as given in the file. However, special treatment is given to annotations of the types CDS, exon, mRNA, transcript and gene. For these, the following applies:
• A gene annotation is generated for each gene_id. The region annotated extends from the leftmost to the rightmost positions of all annotations that have the gene_id (gtf-style).
• CDS annotations that have the same transcriptID are joined to one CDS annotation (gtf-style). Similarly, CDS annotations that have the same parent are joined to one CDS annotation (gff-style).
• If there is more than one exon annotation with the same transcriptID these are joined to one mRNA annotation. If there is only one exon annotation with a particular transcriptID, and no CDS with this transcriptID, a transcript annotation is added instead of the exon annotation (gtf-style).
• Exon annotations that have the same parent mRNA are joined to one mRNA annotation. Similarly, exon annotations that have the same parent transcript, are joined to one transcript annotation (gff-style).

Note that genes and transcripts are linked by name only (not by position, ID etc).

For a comprehensive source of genomic annotation of genes and transcripts, we refer to the Ensembl web site at http://www.ensembl.org/info/data/ftp/index.html. On this page, you can download GTF files that can be used to annotate genomes for use in other analyses in the workbench. You can also read more about these formats at http://www.sanger.ac.uk/resources/software/gff/spec.html, http://mblab.wustl.edu/GTF22.html, and https://genomebiology.biomedcentral.com/articles/10.1186/gb-2010-11-8-r88.

**GFF3** A GFF3 file contains a list of various types of annotations that can be linked together with "Parent" and "ID" tags. Learn more about how the workbench handles GFF3 format in section 6.2.1.

**VCF** This is the file format used for variants by the 1000 Genomes Project and it has become a standard format. Read about VCF format here https://samtools.github.io/hts-specs/VCFv4.2.pdf. Learn how to access data at http://www.1000genomes.org/data/DataAccess. When importing a single VCF file, you will get a track for each sample contained in the VCF file. In cases where more than one sample is contained in a VCF file, you can choose to import the files together or individually by using the batch mode found in the lower left side of the wizard shown in figure 6.2. The difference between the two import modes is that the batch mode will import the samples individually in separate track files, whereas the non-batch mode will keep variants for one sample in one track, thus merging samples from the different input files (in cases where the same sample is contained in different input files). If you import more than one VCF file that each contain more than one sample, the non-batch mode will generate one track file for each unique sample. The batch mode will generate a track file for each of the original VCF files with the entire content, as if importing each of the VCF files one by one. For example, VCF file 1 contains sample 1 and sample 2, and VCF file 2 contains sample 2 and sample 3. When VCF file 1 and VCF file 2 are imported in non-batch mode, you will get three individual track files; one for each of the three samples 1, 2, and 3. If VCF file 1 and VCF file 2 were instead imported using the batch function, the result of the import would be four track files: a track from sample 1 from file 1, a track from sample 2 from file 1, a track from sample 2 from file 2, and a track from sample 3 from file 2.

**Complete Genomics master var file** This is the file format used by Complete Genomics for all kinds of variant data and can be used to analyze and visualize the variant calls made
by Complete Genomics. Please note that you can import evidence files with the read alignments into the CLC Genomics Workbench as well (refer to the Complete Genomics import section of the Workbench user manual).

**BED** Simple format for annotations. Read more at [http://genome.ucsc.edu/FAQ/FAQformat.html#format1](http://genome.ucsc.edu/FAQ/FAQformat.html#format1). This format is typically used for very simple annotations, for example target regions for sequence capture methods.

**Wiggle** The Wiggle format as defined by UCSC ([http://genome.ucsc.edu/goldenPath/help/wiggle.html](http://genome.ucsc.edu/goldenPath/help/wiggle.html)), is used to hold continuous data like conservation scores, GC content etc. When imported into the CLC Genomics Workbench, a graph track is created. An example of a popular Wiggle file is the conservation scores from UCSC which can be downloaded for human from [http://hgdownload.cse.ucsc.edu/goldenPath/hg19/phastCons46way/](http://hgdownload.cse.ucsc.edu/goldenPath/hg19/phastCons46way/).

**UCSC variant database table dump** Table dumps of variant annotations from the UCSC can be imported using this option. Mainly files ending with .txt.gz on this list can be used: [http://hgdownload.cse.ucsc.edu/goldenPath/hg19/database/](http://hgdownload.cse.ucsc.edu/goldenPath/hg19/database/). Please note that importer is for variant data and is not a general importer for all annotation types. This is mainly intended to allow you to import the popular Common SNPs variant set from UCSC. The file can be downloaded from the UCSC web site here: [http://hgdownload.cse.ucsc.edu/goldenPath/hg19/database/snp138Common.txt.gz](http://hgdownload.cse.ucsc.edu/goldenPath/hg19/database/snp138Common.txt.gz). Other sets of variant annotation can also be downloaded in this format using the UCSC Table Browser.

**COSMIC variation database** This lets you import the COSMIC database, which is a well-known publicly available primary database on somatic mutations in human cancer. The file can be downloaded from the UCSC web site here: [http://cancer.sanger.ac.uk/cancergenome/projects/cosmic/download](http://cancer.sanger.ac.uk/cancergenome/projects/cosmic/download). Users must first register to download the database. Import the file as a track. Through Import->Tracks we support certain COSMIC databases in tsv format that can be manually downloaded from the COSMIC ftp site:

- COSMIC Complete mutation data: CosmicCompleteTargetedScreensMutantExport.tsv
- COSMIC Mutation Data (Genome Screens): CosmicGenomeScreensMutantExport.tsv
- COSMIC Mutation Data: CosmicMutantExport.tsv
- All Mutations in Census Genes: CosmicMutantExportCensus.tsv

Please see chapter I.1.6 for more information on how different formats (e.g. VCF and GVF) are interpreted during import in CLC format. For all of the above, zip files are also supported. Please note that for human data, there is a difference between the UCSC genome build and Ensembl/NCBI for the mitochondrial genome. This means that for the mitochondrial genome, data from UCSC should not be mixed with data from other sources (see [http://hgdownload.soe.ucsc.edu/goldenPath/hg19/bigZips/](http://hgdownload.soe.ucsc.edu/goldenPath/hg19/bigZips/)). Most of the data above is annotation data and if the file includes information about allele variants (like VCF, Complete Genomics and GVF), it will be combined into one variant track that can be used for finding known variants in your experimental data. When the data cannot be recognized as variant data, one track is created for each annotation type. Genome / gene annotation tracks can be automatically imported from relevant databases as described here: [http://resources.qiagenbioinformatics.com/manuals/clcgenomicsworkbench/current/index.php?manual=Selecting_data_types_download.html](http://resources.qiagenbioinformatics.com/manuals/clcgenomicsworkbench/current/index.php?manual=Selecting_data_types_download.html).
For all types of files except fasta, you need to select a reference track as well. This is because most the annotation files do not contain enough information about chromosome names and lengths which are necessary to create the appropriate data structures.

### 6.2.1 GFF3 format

A GFF3 file contains a list of various types of annotations that can be linked together with "Parent" and "ID" tags.

Here are some example of a few common tags used by the format:

- **ID** IDs for each feature must be unique within the scope of the GFF file. In the case of discontinuous features (i.e., a single feature that exists over multiple genomic locations) the same ID may appear on multiple lines. All lines that share an ID collectively represent a single feature.

- **Parent** A parent ID can be used to group exons into transcripts, transcripts into genes, and so forth. A feature may have multiple parents. A parent ID can only be used to indicate a 'part of' relationship.

- **Name** The name that will be displayed as a label in the track view. Unlike IDs, there is no requirement that the Name be unique within the file.

Figure 6.3 exemplifies how tags are used to create annotations.

In the workbench, the GFF3 importer will create an output track for each feature type present in the file.

- **Gene-like types.** These are types described in the Sequence Ontology as being subtypes of genes, e.g. ncRNA_gene, plastid_gene, tRNA_gene. Gene-like types are gathered together into an aggregated track with a name of the form "myFileName (Gene)". We recommend that users use this file in RNA-Seq.

- **Transcript-like types.** These are types described in the Sequence Ontology as being subtypes of transcripts that are neither primary transcripts (i.e., they do not require further processing to become functional), nor fusion transcripts. Again, there are several dozen, such as mRNA, Inc_RNA, threonyl_RNA. Transcript-like types are gathered together into an aggregated track with a name of the form "myFileName (RNA)". We recommend that users use this file in RNA-Seq.

- **Exons.** Where possible, exons are merged into their parent features. For example, the output of the lines shown in figure 6.4 will be a single mRNA feature with four exonic regions (from 1300 to 1500, 3000 to 3902, 5000 to 5500, and 7000 to 9000), and no exon features will be output on their own. However, in cases where the parent is of a "gene-like" type, exons are output as their own independent features in the exon track. Finding a lot of features in the exon track can suggest a problem with the file being imported. However, with large databases, this is more likely to be due to the database creators choosing to represent pseudogenes as exons with no transcript.
CHAPTER 6. IMPORT/EXPORT OF DATA AND GRAPHICS

Figure 6.3: Example of a GFF3 file and the corresponding annotations from https://github.com/The-Sequence-Ontology/Specifications/blob/master/gff3.md.

Figure 6.4: Exons will be merged into their parent features when the parent is not a "gene-like" type.

- **CDS** CDS regions with the same parent are joined together into a single spliced feature. If CDS features do not have a parent they are instead joined based on their ID, as for any other feature (described below)

- **Features with the same ID** Regardless of the feature type, features that have the same ID are merged into a single spliced feature. For example, the output of the following figure 6.5 will be a single cDNA_match feature with regions (1050..1500, 5000..5500, 7000..9000).

Figure 6.5: Features that have the same ID are merged into a single spliced feature.

Naming of features
When one of the following qualifiers is present, it will be used for naming in the prioritized order:

1. the "Name" of the feature
2. the "Name" of the first named parent of the feature
3. the "ID" of the feature
4. the "ID" of the first parent
5. the type of the feature

Several examples of naming strategies are depicted in figure 6.6.

![Figure 6.6: Naming of features.](image)

Merged CDS features have a slightly different naming scheme. First, if a CDS feature in the GFF3 file has more than one parent, we create one CDS feature in the workbench for each parent, and each is merged with all other CDS features from the GFF3 file that has the parent feature as parent as well. The naming is then done in the following prioritized order:

1. the "Name" of the feature, if all the constituent CDS features have the same "Name".
2. the "Name" of the first named parent of the feature, if it has a name.
3. the "Name" of the first of the merged CDS features with a name.
4. the "ID" of the first of the merged CDS features with an ID.
5. the "ID" of the parent.

For features with the same ID, the naming scheme is as follows:

1. the "Name" of the feature, if all have the same "Name".
2. If there is a set of common parents for the features and one of the common parents have a "Name", the name of the first common parent with a "Name" is used.
3. If at least one feature has a name, the name of the first feature with the name is used.
4. the "ID" of the first of the features

**Limits of the GFF3 importer**

Features are imported only if their SeqID (i.e., the value in the first column of the gff3) can be matched to the name of a chromosome in the genome. Matching need not be exact (see section I.1.6). However, in some cases it may be necessary to manually edit either the names of the genomic sequences (for example in a fasta file), or the SeqIDs in the GFF3 file so that they match. Features without a match aren’t imported. You can see the number of skipped features in the importer log.

The start and stop position of a feature cannot extend beyond the ends of a chromosome, unless the chromosome is explicitly marked as circular, which is indicated by << and >> at the beginning and the end of the sequence.

Trying to import such a file will fail. One option is to delete the feature that extends beyond the end of the chromosome and to start the import again. Another option is to make the track circular. To do so, convert the linear track into a sequence using the Convert from Tracks tool. Open the sequence and right-click on its name to be able to choose the option "Make sequence circular" from the drop-down menu. Convert the now circular sequence back into a track using the Convert to Tracks tool. Importing the gff3 should now be working.

The following instances are not supported:

- Interpreting SOFA accession numbers. The type of the feature is constrained to be either: (a) a term from the "lite" sequence ontology, SOFA; or (b) a SOFA accession number, distinguished using the syntax SO:000000. The importer recognizes terms from SOFA as well as terms from the full Sequence Ontology, but will not translate accession numbers to types. So for example, features with type SO:0000316 will not be interpreted as "CDS" but will be handled like any other type.

- The fasta directive ##FASTA. This FASTA section situated at the end of a GFF3 file specifies sequences of ESTs as well as of contigs. The GFF3 importer will ignore these sequences.

- Alignments. An aligned feature is handled as a single region, with the Gap and Target attributes added as annotations. We do not use Gap and Target to show how the feature aligns.

- Comment lines. We do not interpret lines beginning with a #. Especially relevant are lines "##sequence-region seqid start end" which some parsers use to perform bounds checking of features. Our bounds checking is instead performed against the user-supplied genome.

**6.3 Import high-throughput sequencing data**

*CLC Genomics Workbench* has dedicated tools for importing data from the following High-throughput sequencing systems:

- QIAGEN GeneReader
- Illumina Genome Analyzer, Nextseq, HiSeq and MiSeq
• PacBio
• Ion Torrent

It is also possible to import mapped data in SAM/BAM format, meaning that alignments of Complete Genomics data can be imported using the SAM/BAM importer.

An importer for Roche 454 sequencing data is available in the Legacy Tools folder. While we do not support the import of files in Complete Genomics master VAR file format, these files can be converted to VCF using the tools provided by Complete Genomics, and later imported in the workbench as VCF.

Having dedicated tools for importing NGS data helps standardize the data so that downstream analyses and visualization work seamlessly with all sequencing platforms. In case a sequence list was not imported with the right tool, it is possible to edit "Read Group" information in the "Element Info" view: choose from the drop-down menu the sequencing platform that was used to generate the data (figure 6.7) and click OK.

![Figure 6.7: Editing the platform that was used to generate the data in the "Element Info" view.](image)

Clicking on the Import button in the top toolbar will bring up a list of the supported data types as shown in figure 6.8.

Select the appropriate format and then fill in the information as explained in the following sections.

6.3.1 QIAGEN GeneReader

CLC Genomics Workbench supports data from QIAGEN GeneReader. Choosing the QIAGEN GeneReader import will open the dialog shown in figure 6.9.

The file formats accepted are Fastq *.fastq and *.fq. You can choose to discard read names during import.

6.3.2 Illumina

CLC Genomics Workbench supports data from Illumina’s Genome Analyzer, HiSeq 2000, NextSeq and the MiSeq systems. Choosing the Illumina import will open the dialog shown in figure 6.10.
Chapter 6. Import/Export of Data and Graphics

Figure 6.8: Choosing what kind of data you wish to import.

Figure 6.9: Importing data from QIAGEN GeneReader.

File format The file formats accepted are:

- Fastq
- Scarf
- Qseq
- For all formats, compressed data in gzip format is also supported (.gz).

Paired data in any of these formats can be imported.

Note that there is information inside qseq and fastq files specifying whether a read has passed a quality filter or not. If you check Remove failed reads these reads will be ignored during import. For qseq files there is a flag at the end of each read with values 0 (failed) or 1 (passed). In this example, the read is marked as failed and if Remove failed reads is checked, the read is removed.
For fastq files, part of the header information for the quality score has a flag where Y means failed and N means passed. In this example, the read has not passed the quality filter:

```
@EAS139:136:FC706VJ:2:2104:15343:197393 1:Y:18:ATCACG
```

**Note!** In the **Illumina pipeline 1.5-1.7**, the letter B in the quality score has a special meaning. 'B' is used as a trim clipping. This means that when selecting Illumina pipeline 1.5-1.7, the reads are automatically trimmed when a B is encountered at either end of the reads in the input file. This will happen also if you choose to discard quality scores during import.

**General Options**  The General options to the left are:

- **Paired reads.** For paired import, you can select whether the data is Paired-end or Mate-pair. For paired data, the Workbench expects the first reads of the pairs to be in one file and the second reads of the pairs to be in another. So, for example, if you had specified that the pairs were in forward-reverse orientation, then the first file would be assumed to contain the forward reads. The second file would be assumed to contain the reverse reads.

  When loading files containing paired data, the **CLC Genomics Workbench** sorts the files selected according to rules based on the file naming scheme:

  - For files coming off the CASAVA1.8 pipeline, we organize pairs according to their identifier and chunk number. Files named with 
    _R1_ are assumed to contain the first sequences of the pairs, and those with _R2_ in the name are assumed to contain the second sequence of the pairs.
  
  - For other files, we sort them all alphanumerically, and then group them two by two. This means that files 1 and 2 in the list are loaded as pairs, files 3 and 4 in the list are seen as pairs, and so on.
In the simplest case, the files are typically named as shown in figure 6.10. In this case, the data is paired end, and the file containing the forward reads is called `s_1_1_sequence.txt` and the file containing reverse reads is called `s_1_2_sequence.txt`. Other common filenames for paired data, like `_1_sequence.txt`, `_1_qseq.txt`, `_2_sequence.txt` or `_2_qseq.txt` will be sorted alphanumerically. In such cases, files containing the final `_1` should contain the first reads of a pair, and those containing the final `_2` should contain the second reads of a pair.

For files from CASAVA1.8, files with base names like these: ID_R1_001, ID_R1_002, ID_R2_001, ID_R2_002 would be sorted in this order:

1. ID_R1_001
2. ID_R2_001
3. ID_R1_002
4. ID_R2_002

The data in files ID_R1_001 and ID_R2_001 would be loaded as a pair, and ID_R1_002, ID_R2_002 would be loaded as a pair.

Within each file, the first read of a pair will have a 1 somewhere in the information line. In most cases, this will be a /1 at the end of the read name. In some cases though (e.g. CASAVA1.8), there will be a 1 elsewhere in the information line for each sequence. Similarly, the second read of a pair will have a 2 somewhere in the information line - either a /2 at the end of the read name, or a 2 elsewhere in the information line.

If you do not choose to discard your read names on import (see next parameter setting), you can quickly check that your paired data has imported in the pairs you expect by looking at the first few sequence names in your imported paired data object. The first two sequences should have the same name, except for a 1 or a 2 somewhere in the read name line.

Paired-end and mate-pair data are handled the same way with regards to sorting on filenames. Their data structure is the same the same once imported into the Workbench. The only difference is that the expected orientation of the reads: reverse-forward in the case of mate pairs, and forward-reverse in the case of paired end data. Read more about handling paired data in section 6.3.7.

- **Discard read names.** For high-throughput sequencing data, the naming of the individual reads is often irrelevant given the huge amount of reads. This option allows you to discard read names to save disk space.

- **Discard quality scores.** Quality scores are visualized in the mapping view and they are used for SNP detection. If this is not relevant for your work, you can choose to Discard quality scores. One of the benefits from discarding quality scores is that you will gain a lot in terms of reduced disk space usage and memory consumption. Read more about the quality scores of Illumina below.

**Paired read information** These options become available if you selected the option "Paired reads" in the General options. First, it is very important to select the correct nature of the paired reads imported: Paired-end (forward-reverse) or Mate-pair (reverse-forward). Second, you have to specify the Minimum and Maximum distances for your pairs. The paired read distance includes the full read sequence, which means that is from the beginning of the forward read to
the beginning of the reverse read (figure 6.11). The distances are usually defined during the library preparation of your sequencing experiment, but in doubt you can enter default values: for paired-end the distances are between 1 and 1000 bp while mate-pair reads typically have longer distances between 1000-5000 bp (and sometimes up to 10000). Note that the tools usually used subsequently to process Illumina reads (such as "Map Reads to Reference" or "RNA-Seq Analysis") have an "Auto-detect paired distances" option that is enabled by default. As long as this option is used, mis-specifying the distances during import should bear no consequences.

![Figure 6.11: Green lines represent forward reads, red lines reverse reads, and in blue is shown the distance of the sequenced DNA fragment. Thus, if there is a complete overlap, the minimum distance will not be 0, but the length of the overlap.](image)

**Illumina options**

- **Remove failed reads.** If you check Remove failed reads, reads that did not pass a quality filter (in qseq and fastq files) will be ignored during import. For more information on format specific quality filters see section on file format above). If you import paired data and one read in a pair is removed during import, the remaining mate will be saved in a separate sequence list with single reads.

- **MiSeq de-multiplexing.** Using this option on MiSeq multiplexed data will divide reads into different files based on the "IndexSequence" of the read header:

  ```
  @Instrument:RunID:FlowCellID:Lane:Tile:X:Y:UMI ReadNum:FilterFlag:0:IndexSequence
  ```

  Subsequent analysis can then be executed in batch on all the files, and results can be compared at the end.

- **Trim reads.** This option applies to Illumina Pipeline 1.5 to 1.7. In this pipeline, the value 2 (B) has special meaning and is used as a trim clipping. This means that when selecting Illumina Pipeline 1.5 and later, the reads are trimmed when a B is encountered at either end of the reads in the input file if the Trim reads option is checked.

Click Next to adjust how to handle the results (see section 9.2). We recommend choosing Save in order to save the results directly to a folder, since you probably want to save anyway before proceeding with your analysis. There is an option to put the import data into a separate folder. This can be handy for better organizing subsequent analysis results and for batching (see section 9.3).
Quality scores in the Illumina platform

The quality scores in the FASTQ format come in different versions. You can read more about the FASTQ format at [http://en.wikipedia.org/wiki/FASTQ_format](http://en.wikipedia.org/wiki/FASTQ_format). When you select to import Illumina data and click Next there is an option to use different quality score schemes at the bottom of the dialog (see figure 6.12).

![Figure 6.12: Selecting the quality score scheme.](image)

There are four options:

- **NCBI/Sanger or Illumina 1.8 and later.** Using a Phred scale encoded using ASCII 33 to 93. This is the standard for fastq formats except for the early Illumina data formats (this changed with version 1.8 of the Illumina Pipeline).

- **Illumina Pipeline 1.2 and earlier.** Using a Solexa/Illumina scale (-5 to 40) using ASCII 59 to 104. The Workbench automatically converts these quality scores to the Phred scale on import in order to ensure a common scale for analyses across data sets from different platforms (see details on the conversion next to the sample below).

- **Illumina Pipeline 1.3 and 1.4.** Using a Phred scale using ASCII 64 to 104.

- **Illumina Pipeline 1.5 to 1.7.** Using a Phred scale using ASCII 64 to 104. Values 0 (@) and 1 (A) are not used anymore. Value 2 (B) has special meaning and is used as a trim clipping. This means that when selecting Illumina Pipeline 1.5 and later, the reads are trimmed when a B is encountered at either end of the reads in the input file if the Trim reads option is checked.

Small samples of three kinds of files are shown below. The names of the reads have no influence on the quality score format:

NCBI/Sanger Phred scores:

```
@SRR001926.1 FC00002:7:1:111:750 length=36
TTTTTGTAGGAGGGGTCATCAAAATTTGCAAAA
+SRR001926.1 FC00002:7:1:111:750 length=36
IIIIIIIIIIIIIIIIIIIIIIIIIIIB<IH
@SRR001926.7 FC00002:7:1:110:453 length=36
TTATATGAGGCTTTAAGAGTCATAGGTTGTTCCCC
+SRR001926.7 FC00002:7:1:110:453 length=36
IIIIIIIIIIIIIII:’III?=IIIIII+IIII/3I8F/&
```
Illumina Pipeline 1.2 and earlier (note the question mark at the end of line 4 - this is one of the values that are unique to the old Illumina pipeline format):

• SAM or BAM files (.sam/.bam). The mapping information is discarded during import.

Under **General options** you have the following choices:

- **Discard read names.** For high-throughput sequencing data, the naming of the individual reads is often irrelevant given the huge amount of reads. This option allows you to discard read names to save disk space.

- **Discard quality scores.** Quality scores can be visualized in the mapping view and used for SNP detection. If this is not relevant for your work, you can choose to **Discard quality scores.** Discarding quality scores will reduce both disk space usage and memory consumption. As PacBio quality scores currently contain very little information, we recommend that you discard them. When importing Fasta files, this option is not available, since Fasta files do not contain quality scores.

Click **Next** and choose how the result of the import should be handled. We recommend choosing **Save** which will save the results directly to the disk.

When opening the "Element info" of sequence lists imported with the PacBio importer, the item "Platform" will display the mention PACBIO. For PacBio reads imported without the PacBio importer, it is possible to edit that field to "PACBIO" by clicking **Edit** next to the "Read Group" section in the Element Info view. Having the platform set to PacBio will ensure that the read mapper will perform better on PacBio reads.

### 6.3.4 Fasta read files

The **Fasta** importer is designed for high volumes of read data such as high-throughput sequencing data (NGS reads). When using this import option the read names can be included but the descriptions from the fasta files are ignored.

For import of other fasta format data, such as reference sequences, please use the **Standard Import** as this import format also includes the descriptions. To have a reference in track format, use the **Tracks** option and set the "Type of file to import" to FASTA.

The dialog for importing data in fasta format is shown in figure 6.14.
Figure 6.14: Importing data in fasta format.

Compressed data in gzip format is also supported (.gz).

The **General options** to the left are:

- **Paired reads.** For paired import, the Workbench expects the forward reads to be in one file and the reverse reads in another. The Workbench will sort the files before import and then assume that the first and second file belong together, and that the third and fourth file belong together etc. At the bottom of the dialog, you can choose whether the ordering of the files is **Forward-reverse** or **Reverse-forward**. As an example, you could have a data set with two files: `sample1_fwd` containing all the forward reads and `sample1_rev` containing all the reverse reads. In each file, the reads have to match each other, so that the first read in the `fwd` list should be paired with the first read in the `rev` list. Note that you can specify the insert sizes when importing paired read data. If you have data sets with different insert sizes, you should import each data set individually in order to be able to specify different insert sizes. Read more about handling paired data in section 6.3.7.

- **Discard read names.** For high-throughput sequencing data, the naming of the individual reads is often irrelevant given the huge amount of reads. This option allows you to discard this option to save disk space.

- **Discard quality scores.** This option is not relevant for fasta import, since quality scores are not supported.

Click **Next** to adjust how to handle the results (see section 9.2). We recommend choosing **Save** in order to save the results directly to a folder, since you probably want to save anyway before proceeding with your analysis. There is an option to put the import data into a separate folder. This can be handy for better organizing subsequent analysis results and for batching (see section 9.3).

### 6.3.5 Sanger sequencing data

Although traditional sequencing data (with chromatogram traces like abi files) is usually imported using the standard **Import** (\(\overline{\text{i}}\)), see section 6, this option has also been included in the High-Throughput Sequencing Data import. It is designed to handle import of large amounts of sequences, and there are three differences from the standard import:
• All the sequences will be put in one sequence list (instead of single sequences).

• The chromatogram traces will be removed (quality scores remain). This is done to improve performance, since the trace data takes up a lot of disk space and significantly impacts speed and memory consumption for further analysis.

• Paired data is supported.

With the standard import, it is practically impossible to import up to thousands of trace files and use them in an assembly. With this special High-Throughput Sequencing import, there is no limit. The import formats supported are the same: ab, abi, ab1, scf and phd.

For all formats, compressed data in gzip format is also supported (.gz).

The dialog for importing data Sanger sequencing data is shown in figure 6.15.

![Figure 6.15: Importing data from Sanger sequencing.](image)

The General options to the left are:

• **Paired reads.** The Workbench will sort the files before import and then assume that the first and second file belong together, and that the third and fourth file belong together etc. At the bottom of the dialog, you can choose whether the ordering of the files is **Forward-reverse** or **Reverse-forward**. As an example, you could have a data set with two files: `sample1_fwd` for the forward read and `sample1_rev` for the reverse reads. Note that you can specify the insert sizes when importing paired read data. If you have data sets with different insert sizes, you should import each data set individually in order to be able to specify different insert sizes. Read more about handling paired data in section 6.3.7.

• **Discard read names.** For high-throughput sequencing data, the naming of the individual reads is often irrelevant given the huge amount of reads. This option allows you to discard this option to save disk space.

• **Discard quality scores.** Quality scores are visualized in the mapping view and they are used for SNP detection. If this is not relevant for your work, you can choose to **Discard quality scores**. One of the benefits from discarding quality scores is that you will gain a lot in terms of reduced disk space usage and memory consumption.

Click **Next** to adjust how to handle the results (see section 9.2). We recommend choosing **Save** in order to save the results directly to a folder, since you probably want to save anyway before
proceeding with your analysis. There is an option to put the import data into a separate folder. This can be handy for better organizing subsequent analysis results and for batching (see section 9.3).

### 6.3.6 Ion Torrent

Choosing the Ion Torrent import will open the dialog shown in figure 6.16.

The **General options** to the left are:

- **Paired reads.** The CLC Genomics Workbench supports both paired end and mate pair protocols.

  **Paired end** Paired end data from Ion Torrent comes in two files per data set. The first file in is assumed to contain the first reads of the pair, and the second file is assumed to contain the second read in a pair. On import, the orientation of the reads is set to forward - reverse. When the reads have been imported, there will be one file with intact pairs, and one file where one part of the pair is missing (in this case, "single" is appended to the file name). The Workbench connects the right sequences together in the pair based on the read name. Read more about handling paired data in section 6.3.7.

  **Mate pair** Mate pair reads from Ion Torrent are Reverse-Forward and usually between 2,000 and 10,000 bp. The mate pair protocol for Ion Torrent entails that the two reads are separated by a linker sequence. During import of paired data, the linker sequence is

We support import of the following data from the Ion Torrent system:

- **SFF files (.sff)** providing extra information on adapters or regions of low quality

- **Fastq files (.fastq).** Quality scores are expected to be in the NCBI/Sanger format (see section 6.3.2). Compressed data in gzip format is also supported (.gz).

- **SAM or BAM files (.sam/.bam).** The mapping information is discarded during import.
removed and the two reads are separated and put into the same sequence list. You can change the linker sequence in the Preferences (in the Edit menu) under Data. When looking for the linker sequence, the Workbench requires 80% of the maximum alignment score, using the following scoring scheme: matches = 1, mismatches = -2 and indels = -3. Some of the sequences may not have the linker in the middle of the sequence, and in that case the partial linker sequence is still removed, and the single read is put into a separate sequence list. Thus when you import Ion Torrent mate pair data, you may end up with two sequence lists: one for paired reads and one for single reads. Note that for de novo assembly projects, only the paired list should be used since the single reads list may contain reads where there is still a linker sequence present but only partially due to sequencing errors. Read more about handling paired data in section 6.3.7.

- **Discard read names.** For high-throughput sequencing data, the naming of the individual reads is often irrelevant given the huge amount of reads. This option allows you to discard this option to save disk space.

- **Discard quality scores.** Quality scores are visualized in the mapping view and they are used for SNP detection. If this is not relevant for your work, you can choose to **Discard quality scores.** One of the benefits from discarding quality scores is that you will gain a lot in terms of reduced disk space usage and memory consumption. If you have selected the fna/qual option and choose to discard quality scores, you do not need to select a .qual file.

For sff files, you can also decide whether to use the clipping information in the file or not.

### 6.3.7 General notes on handling paired data

During import, information about paired data (distances and orientation) can be specified (see figure 6.10) and stored by the CLC Genomics Workbench. All subsequent analyses automatically take differences in orientation into account. Once imported, both reads of a pair will be stored in the same sequence list. The forward and reverse reads (e.g. for paired-end data) simply alternate so that the first read is forward, the second read is the mate reverse read; the third is again forward and the fourth read is the mate reverse read and so on. When manipulating sequence lists with paired data, be careful not break this order.

You can view and edit the orientation of the reads after they have been imported by opening the read list in the Element information view (\(\square\)), see section 11.4 as shown in figure 6.17.

Figure 6.17: The paired orientation and distance.

In the **Paired status** part, you can specify whether the CLC Genomics Workbench should treat the data as paired data, what the orientation is and what the preferred distance is. The orientation
and preferred distance is specified during import and can be changed in this view. If the "Paired sequences" box is unchecked, the sequences will be handled as single (non paired) data.

Note that the **paired distance** measure that is used throughout the *CLC Genomics Workbench* is always **including the full read sequence**. For paired-end libraries it means from the beginning of the forward read to the beginning of the reverse read.

### 6.3.8 SAM and BAM mapping files

The *CLC Genomics Workbench* supports import and export of files in SAM (Sequence Alignment/Map) and BAM format, which are designed for storing large nucleotide sequence alignments. Read more and see the format specification at [http://samtools.sourceforge.net/](http://samtools.sourceforge.net/)

The *CLC Genomics Workbench* includes support for importing SAM and BAM files from **Complete Genomics**.

**Note!** If you wish to import the reads in a SAM/BAM file as a sequence list, disregarding any mapping information, please use the Standard import tool instead (see section 6.1).

For a detailed explanation of the SAM and BAM files exported from *CLC Genomics Workbench*, please see Appendix J.

**Input data for importing a mapping from a SAM/BAM file**

To import a mapping from a SAM/BAM file containing mapping data into the Workbench, you need to:

- Provide the SAM/BAM file
- Specify the reference sequences that are referred to within that file. The references can either be sequences already imported into the Workbench, or, if appropriately recorded in the SAM/BAM file, can be fetched from URLs specified in the SAM/BAM file.

The mapping is built up within the Workbench using the reference sequence data, the reads and the information from the SAM/BAM file about how the reads are associated with a particular reference.

**Data created in the Workbench after importing a SAM/BAM mapping file**

- Reads recorded as mapping to a particular reference that is known inside the Workbench are imported as part of the mapping for that reference.
- Reads recorded as not mapping to any reference are imported into a sequence list.
  - If they are part of an intact pair, they are imported into a sequence list of paired data.
  - If they are single reads or a member of a pair that did not map while its mate did, they are imported into a sequence list containing single reads.

One list is made per read group, with the potential that several such lists could be produced from a single mapping import. The sequence lists are given names of this form for single reads "<read group id> [read group sample] (single) un-mapped reads" and this form for paired reads "<read group id> [read group sample] (paired) un-mapped reads".
If you do not wish to import the unmapped reads, deselect the **Import unmapped reads** option in the final step of the tool dialog.

- Reads recorded as mapping to a reference sequence that is **not** known within the Workbench are not imported.

When setting up the import, you are given the option of creating a track-based mapping, or a stand-alone mapping. In the latter case, if there is only one reference sequence, the result will be a single read mapping (single). When there is more than one reference sequence, a multi-mapping object (multi) is created.

Please note that mappings within the **CLC Genomics Workbench** do not allow for an individual read sequence to map to more than one location. In cases where a SAM/BAM file contains multiple alignment records for a single read, only one such record will be used to build the mapping.

**Running the SAM/BAM Mapping Files importer**

Click on the Import button on the toolbar or go to:

```
File | Import (Import) | SAM/BAM Mapping Files (Import)
```

This will open a dialog where you select the SAM/BAM file to import as well as the reference sequences to be used (Figure 6.18).

When you select the reference sequence(s) two options exist:

1. Select a matching reference sequence that has already been imported into the Workbench. Click on the "Find in folder" icon (Find in folder) to localize the reference sequence.

2. If the SAM/BAM file already contains information about where to find the reference sequence, tick the "Download references" box to automatically download the reference sequence.

The selected reference sequence(s) will be listed under "References in files" with "Name", "Length", and "Status". Whenever the correct reference sequence (with the correct name and sequence length) has been selected the "Status" field will indicate this with an "OK". The length of your reference sequence must **match exactly** the length of the reference specified in the SAM/BAM file. The name is more flexible as it allows a range of different "synonyms" (with no distinction between capital and lowercase letters). E.g. for chromosome 1 the allowed synonyms would be: 1, chr1, chromosome_1, nc_000001, for chromosome M: m, mt, chm, chrmt, chromosome_m, chromosome mt, nc_001807, for chromosome X: x, chrx, chromosome_x, nc_000023, and for chr Y: y, chry, chromosome_y, nc_000024.

If there are inconsistencies in the names or lengths of the reference sequences being chosen and those recorded in the SAM/BAM file, an entry will appear in the "Status" column indicating this (for example, "Length differs" or "Input missing")

Unmatched reads (reads that are mapped to an unmatched reference e.g. a SAM reference for which there is no CLC reference counterpart) are not imported. The same is the case whenever

---

1If you are using a CLC Genomics Server to import files located on the Server (rather than locally), then checks for corresponding reference names and lengths cannot be carried out, so nothing will be reported in this section of the Wizard. This means you will be able to continue to launch the import with correct or incorrect reference sets specified. However, any inconsistencies in these will lead to the import task failing with an error related to this.
inconsistencies have occurred with respect to name or length. The log lists all mapping data or unmatched reads that were not imported and marks whether import failed because of unmatched reads being present in the SAM/BAM file or because of inconsistencies in name/length.

**Some notes regarding reference sequence naming** Reference sequences in a SAM/BAM file **cannot contain spaces.** If the name of a reference sequence in the Workbench contains spaces, the Workbench assume that the names of the references in the SAM file will be the same as the names of the References within the Workbench, but with all spaces removed. For example, if your reference sequence in the Workbench was called my reference sequence, the Workbench would recognize a reference in the SAM file as the appropriate reference if it was of the same length and had the name myreferencesequence.

Neither the @ character nor the = character are allowed within reference sequence names in SAM files. Any instances of these characters in the name of a reference sequence in the Workbench will be replaced with a _ for the sake of identifying the appropriate reference when importing a SAM or BAM file. For example, if a reference sequence in the Workbench was called my=reference@sequence, the Workbench would recognize a reference in the SAM file as the appropriate reference if it was of the same length and had the name my_reference_sequence.

Click **Next** to specify how to handle the results (Figure 6.19). Under **Output options** the "Save downloaded reference sequence" will be enabled if the "Download references" box was ticked in the previous step (which would be the case when the SAM/BAM file contained information about where to find the reference sequence e.g. if the SAM/BAM file came from an external provider).

Ticking the "Create Reads Track" box results in the generation of a track-based mapping. Alternatively, the "Create Stand-Alone Read Mapping" results in a normal read mapping file. By ticking the "Import unmapped reads" box, a sequence list of the unmapped reads will be created. To avoid importing unmapped reads, untick this box.

We recommend choosing **Save** in order to save the results directly to a folder, as you will probably wish to save the data anyway before proceeding with your analysis. For further information about how to handle the results, (see section 9.2).

Note that this import operation is very memory-consuming for large data sets, and particularly
those with many reads marked as members of broken pairs in the mapping.

### 6.4 Import RNA spike-in controls

The CLC Genomics Workbench has a dedicated tool for importing RNA spike-in control data: Import | RNA Spike-ins

The wizard offers the option to import a standard ERCC file as provided by Thermo Fisher Scientific, or a custom made one (figure 6.20).

To import a standard ERCC file, look for ERCC Controls Analysis and ERCC Control Annotation files on the Thermo Fisher Scientific website, download both *.txt files on your computer, and start the importer. Select the option "ERCC" and specify the location of the analysis and annotation files in the relevant "ERCC Input Selection" fields at the bottom of the wizard.

For custom-made spike-in controls, choose the "Custom" option and specify in the "Custom Input Selection" field a tab-separated file (*.tsv or *.txt) containing the spike-in data organized as such: sequence name in the first column, nucleotide sequence in the second column, followed by as many columns as necessary to contain the concentrations of the spike-in measures in attomoles/microliters. Concentrations must not contain commas: write 15000 instead of 15,000. Remove any white space and save the table as a tab-separated TSV or TXT file on your
computer.
It is also possible to import Lexogen Spike-in RNA Variant Control Mixes by modifying the SIRV files to fit the custom file requirements. Download the SIRV sequence design overview (XLSX) from the Lexogen website and open it in Excel. In the annotation column, "c" designate the data that should be imported ("i" is under-annotated while "0" is over-annotated). Filter the table to only keep the rows having a 1 in the "c" column, then keep only - and in that order - the sequence name, nucleotide sequence and concentration columns of the remaining rows. Reformat the values to numerical values in attomoles/microliters before saving the table as a *.tsv file. Import the file in the workbench using the "Custom" option.

Once a spike-in file is specified, click Next and choose to Save the file in the Navigation Area for later use in RNA-Seq Analysis.

6.5 Import Primers
6.5.1 Import Primer Pairs

The Import Primer Pairs importer can import descriptions of primer locations from a generic text format file or from a QIAGEN gene panel primer file.

To run the tool, go to:

Import ( ) | Import Primer Pairs ( )

This will open the wizard shown in figure 6.21. The first step is to select the data to import.

![Figure 6.21: Select files to import.](image)

- **Primer File** Click on the folder icon in the right side to select your primer pair location file. There are two primer pair formats that can be imported by the Workbench.

  - **Generic Format** Select this option for primer location files with the exception of QIAGEN gene panel primers. Provide your primer location information in a tab delimited text file with the following columns:
    - Column 1: reference name
    - Column 2: primer1 first position (5’end) on reference
    - Column 3: primer1 last position (3’end) on reference
    - Column 4: primer2 first position (5’end) on reference
CHAPTER 6. IMPORT/EXPORT OF DATA AND GRAPHICS

- Column 5: primer2 last position (3’end) on reference
- Column 6: amplicon name

Note: Primer position intervals are left-open and right-closed, so the leftmost position of the primer on the reference (column 2 and 5) should have one subtracted.

An example of the format expected for each row is:

```
chr1  42  65  142  106  Amplicon1
```

Indicating forward and reverse primers covering the reference nucleotides [43, 65] and [107, 142].

- **QIAGEN Primer Format** Use this option for importing information about QIAGEN gene panel primers.

- **Reference Track** Use folder icon in the right side to select the relevant reference track.

Click on the button labeled **Next** to go to the wizard step choose to save the imported primer location file.

### 6.6 Data export

Data can be exported from the CLC Genomics Workbench to many standard formats. Supported formats are listed in section I.1, but an easy way to see the full list is to launch the Export tool, where they are presented in the first dialog window.

Launch the standard export functionality by clicking on the Export button on the toolbar, or selecting the menu option:

**File | Export**

An additional export tool is available from under the File menu:

**File | Export with Dependent Elements**

This tool is described further in section 6.6.6.

The general steps when configuring a standard export job are:

- (Optional) Select data elements or folders to export in the **Navigation Area**.
- Launch the Export tool by clicking on the Export button in the Workbench toolbar or by selecting **Export** under the File menu.
- Select the format to export the data to.
- Select the data elements to export, or confirm elements that had been pre-selected in the **Navigation Area**.
- Configure the export parameters, including whether to output to a single file, whether to compress the outputs and how the output files should be named. Other format-specific options may also be provided.
- Select where the data should be exported to.
- Click on the button labeled **Finish**.
6.6.1 Export formats

Finding and selecting a format to export to When the Export tool is launched, a list of the available data formats is presented.

You can quickly find a particular format by typing a relevant search term into the text box at the top of the Export window, as shown in figure 6.23. Any formats with that search term in their name or description will be listed in the window. The search term is remembered when the Export tool is next launched. Delete the text from the search box if you wish to have all export formats listed.

Support for choosing an appropriate export format is provided in 2 ways:

- If data elements are selected in the Navigation Area before launching the Export tool, then a "Yes" or a "No" in the Supported formats column specifies whether or not the selected data elements can be exported to that format. If you have selected multiple data elements of different types, then formats that some, but not all, selected data elements can be exported to are indicated by the text "For some elements".

  By default, supported formats appear at the top of the list (figure 6.22).

- If no data elements are selected in the Navigation Area when the Export tool is launched, then the list of export formats is provided, but each row will have a "Yes" in the Supported format column. After an export format has been selected, only the data elements that can be exported to that format will be listed for selection in the next step of the export process.

  Only zip format is supported when a folder, rather than data elements, is selected for export. In this case, all the elements in the folder are exported in CLC format, and a zip file containing these is created. This is described in more detail in section 6.6.5.

Figure 6.22: The Select export format dialog. Here, some sequence lists had been selected in the Navigation Area before the Export tool was launched. The formats that the selected data elements can be exported to contain a "Yes" in the Selected format column. Other export formats are listed below the supported ones, with "No" in the Supported format column.
Figure 6.23: The text field has been used to search for the term "VCF" in the export format name or description field in the Select export dialog.

When the desired export format has been selected, click on the button labeled **Select**.

A dialog then appears, with a name reflecting the format you have chosen. For example if the VCF format was selected, the window is labeled "Export VCF".

If you are logged into a CLC Server, you will be asked whether to run the export job using the Workbench or the Server. After this, you are provided with the opportunity to select or de-select data to be exported.

**Selecting data for export** In figure 6.24 we show the selection of a variant track for export to VCF format.

Figure 6.24: The Select export dialog. Select the data element(s) to export.

### 6.6.2 Export parameters

The settings in the areas **Basic export parameters** and **File name** are offered when exporting to any format.

There may also be additional parameters for particular export formats. This is illustrated for the CLC exporter in figure 6.25.

Examples of configuration options:

- **Compression options.** Within the **Basic export parameters** section, you can choose to compress the exported files. The options are no compression (None), gzip or zip format. Choosing zip format results in all data files being compressed into a single file. Choosing gzip compresses the exported file for each data element individually.

- **Paired reads settings.** In the case of Fastq Export, the option "Export paired sequence lists to two files" is selected by default: it will export paired-end reads to two fastq files rather than a single interleaved file.
CHAPTER 6. IMPORT/EXPORT OF DATA AND GRAPHICS

Figure 6.25: Configure the export parameters. When exporting to CLC format, you can choose to maximize compatibility with older CLC products.

- **Exporting multiple files.** If you have selected multiple files of the same type, you can choose to export them in one single file (only for certain file formats) by selecting "Output as single file" in the **Basic export parameters** section. If you wish to keep the files separate after export, make sure this box is not ticked. **Note:** Exporting in zip format will export only one zipped file, but the files will be separated again when unzipped.

After configuration, choose where to save the exported files to.

### 6.6.3 Choosing the exported file name(s)

The default setting for the **File name** is to use the original data element name as the basename and the export format as the suffix.

When exporting just one data element, or exporting to a zip file, the desired filename could just be typed in the Custom file name box.

When working with the export of multiple files, using some combination of the terms shown by default in this field and in figure 6.26 are recommended. Clicking in the **Custom file name** field with the mouse and then simultaneously pressing the Shift + F1 keys bring up a list of the available terms that can be included in this field.

Figure 6.26: Use the custom file name pattern text field to make custom names.

The following placeholders are available:
• \{input\} or \{1\} - default name of the data element being exported

• \{extension\} or \{2\} - default extension for the chosen export format

• \{counter\} or \{3\} - a number that is incremented per file exported. i.e. If you export more than one file, counter is replaced with 1 for the first file, 2 for the next and so on.

• \{user\} - name of the user who launched the job

• \{host\} - name of the machine the job is run on

• \{year\}, \{month\}, \{day\}, \{hour\}, \{minute\}, and \{second\} - timestamp information based on the time an output is created. Using these placeholders, items generated by a workflow at different times can have different filenames.

In the following example, we would like to change the export file format to .fasta in a situation where .fa was the default format that would be used if you kept the default file extension suggestion ("\{2\}"). To do this, replace "\{2\}" with ".fasta" in the "Custom file name field". You can see that when changing "\{2\}" to ".fasta", the file name extension in the "Output file name" field automatically changes to the new format (see figure 6.27).

![Figure 6.27: The file name extension can be changed by typing in the preferred file name format.](image)

When deciding on an output name, you can choose any combination of the different placeholders as well as custom names and punctuation, as in \{input\}(\{day\}-\{month\}-\{year\})

Another example of a meaningful name to a variant track could be \{2\} variant track as shown in figure 6.28. If your workflow input is named Sample 1, the result would be "Sample 1 variant track".

As you add or remove text and terms in the **Custom file name** field, the text in the **Output file name** field will change so you can see what the result of your naming choice will be for your data. When working with multiple files, only the name of the first one is shown. Just move the mouse cursor over the name shown in the **Output file name** field to show a listing of the all the filenames.
6.6.4 Export in VCF format

CLC Genomics Workbench export variants files in VCF 4.2 format. When exporting VCF files, the following options are available (figure 6.30):

**Reference sequence track**  Since the VCF format specifies that reference and allele sequences cannot be empty, deletions and insertions have to be padded with bases from the reference sequence. The export needs access to the reference sequence track in order to find the neighboring bases.

**Export annotations to INFO field**  Checking this option will export annotations on variant alleles as individual entries in the INFO field. Each annotation gets its own INFO ID. Various annotation tools can be found under Resequencing Analysis | Variant Annotation. Undesired annotations can be removed prior to export using the Remove Information from Variants...
Enforce minimum and maximum ploidy by modifying the number of alleles in the exported VCF genotype (GT) field. The two steps "Enforce minimum ploidy" and "Enforce maximum ploidy" are carried out separately during export in the mentioned order. Note that "Enforce minimum ploidy" can be disabled by setting both Minimum ploidy and Minimum allele fraction threshold to zero. "Enforce maximum ploidy" can be disabled by setting Maximum ploidy to 1000 or more.

- **Minimum** and **Maximum ploidy.** Minimum and maximum number of alleles to be written in the genotype field of the VCF. Enforcing minimum and maximum ploidy only affects the VCF genotype field. Both are set by default to 2, resulting in a VCF file in which the allele values in the Genotype (GT) field for haploid variants are reported following the format for diploid variants (i.e., the GT allele values reported could be 1/1). This is to allow compatibility of the exported VCF file with programs for downstream variant analysis that expect strictly diploid genomes. Note that it is proper to enforce diploid if the sample is diploid, and two alleles are expected to be present at all positions in the variant track (except excluded chromosomes). But if the variants have been filtered in a way that positions are no longer expected to have two alleles (e.g. all reference alleles have been removed), then it becomes wrong to enforce diploid.

- **Minimum allele fraction threshold** (written as a fraction) and **Remove alleles below fraction threshold.** The effect of this threshold depends on the minimum and maximum ploidy values set: for a maximum and minimum ploidy set at 2, and an allele above and one below this threshold, the allele below the threshold will not be considered for the VCF genotype field. For a minimum ploidy set at 2, and a maximum ploidy set at 4,
the "Remove alleles below fraction threshold" option disabled, in the case of 3 alleles where one (A) is above the threshold and two (C and T) are below, the VCF genotype becomes A/A/C/T.

- **Exclude chromosomes from minimum ploidy export.** The user can specify that the Enforce minimum ploidy option is only applied to certain chromosomes, while others will be reported without enforcing a minimum ploidy.

Some chromosomes can be excepted from the enforced diploid export. For a human genome, that would be relevant for the mitochondrion and for male X and Y chromosomes. For this option, you can select which chromosomes should be excepted. They will be exported in the standard way without assuming there should be two genotypes, and homozygous calls will just have one value in the GT field.

**Complex variant representation** Complex variants are allelic variants that overlap but do not cover the same range. In exporting, a VCF line will be written for each complex variant. Choose from the drop down menu:

- Reference overlap: Accurate representation where reference alleles are added to the genotype field to specify complex overlapping alleles.
- Reference overlap and depth estimate: More widely compatible and less accurate representation where a reference allele will be added, and the allele depth will be estimated from the alternate allele depth and coverage.
- Star alleles: Accurate representation where star alleles are used to specify complex overlapping alleles.
- Without overlap specification: this is how complex variants used to be handled in previous versions of the workbench, where complex overlap does not affect how variants are specified.

Read more about these options in section section H

For VCF export, counts from the variant track are put in CLCAD2 or AD fields depending on the chosen complex variant representation, and coverage is placed in the DP field. The values of the CLCAD2 tag follow the order of REF and ALT, with one value for the REF and for each ALT. For example, if there has been a homozygote variant identified at a certain position, the value of the GT field is 1/1 and the corresponding CLCAD2 value for the reference allele will be 0, which is always the first number in the CLCAD2 field. Please note that this does not mean the original mapping did not have any reads with that sequence, but it means that the variant track being exported does not contain the reference allele.

To learn more about VCF specific export format, please read section I.1.6.

### 6.6.5 Export of folders and data elements in CLC format

The **CLC Genomics Workbench** stores data in CLC format. A CLC format file holds all the information for a given data element. This means the data itself, as well as information about that data, like history information.

Data can be exported in CLC format by selecting the CLC format, or the zip format, from the list of available formats.
If CLC format is chosen, each selected data element can be exported to an individual file. An option is offered later in the export process to apply gzip or zip compression. Choosing gzip compression at this stage will compress each data element individually. Choosing zip produces a single file containing the individual CLC format files. If a single zip file containing one or more CLC format files is the desired outcome, choosing the zip format in the first step of the export process specifies this directly.

If a folder is selected for export, only the zip format is supported. In this case, each data element in that folder will be exported to CLC format, and all these files will be compressed in a single zip file.

CLC format files, or zip files containing CLC format data, can be imported directly into a workbench using the Standard Import tool and selecting "Automatic import" in the Options area.

**Backing up and sharing data**

If you are backing up data, or plan to share data with colleagues who have a CLC Workbench, exporting to CLC format is usually the best choice. All information associated with that data element will then be available when the data is imported again. CLC format is also recommended when sharing data with the QIAGEN Bioinformatics Support team.

If you are planning to share your data with someone who does not have access to a licensed CLC Genomics Workbench but just wishes to view the data, then you may still wish to export to CLC format. A CLC Genomics Workbench can be run without a license in Viewing Mode, and CLC format data can be imported in the same way it would be using a licensed Workbench. Viewing Mode is described further in section 1.4.7.

**Compatibility of the CLC data format between Workbench versions**

When exporting to CLC or zip format, an option called **Maximize compatibility with older CLC products** is presented at the **Specify export parameters** step, as can be seen in figure 6.29. With this option checked, data will be exported without internal compression. Data exported with this option turned on may be larger than it would be otherwise.

Internal compression of CLC data was introduced in CLC Genomics Workbench 12.0, CLC Main Workbench 8.1 and CLC Genomics Server 11.0. This feature decreased the size of the data elements created by the software, but CLC format files with internal compression are not compatible with older versions of the software. Thus, this option should be enabled when exporting data intended for use with older CLC software versions. It should not be needed otherwise.

Internal compression is not required for compatibility with Workbench versions released after this feature was introduced. Data generated in older Workbench versions can, in general, be imported into newer Workbench versions. We endeavor to maintain backwards compatibility of CLC format files whenever possible, so that most CLC format files made using an older version of a Workbenches can be imported into newer Workbench versions.

Internal data compression can be turned off, so no data created is internally compressed. How to do this is described in the Workbench Preferences documentation section 4.4.

### 6.6.6 Export of dependent elements

Sometimes it can be useful to export the results of an analysis and its dependent elements. That is, the results along with the data that was used in the analysis. For example, one might wish to
export an alignment along with all the sequences that were used in generating that alignment.

To export a data element with its dependent elements:

- Select the parent data element (like an alignment) in the **Navigation Area**.
- Start up the exporter tool by going to **File | Export with Dependent Elements**.
- Edit the output name if desired and select where the resulting zip format file should be exported to.

The file you export contains compressed CLC format files containing the data element you chose and all its dependent data elements.

A zip file created this way can be imported directly into a CLC workbench by going to

**File | Import ( ) | Standard Import**

and selecting "Automatic import" in the Options area.

**Compatibility of the CLC data format between Workbench versions**

Internal compression of CLC data was introduced in CLC Genomics Workbench 12.0, CLC Main Workbench 8.1 and CLC Genomics Server 11.0. If you are sharing data for use in software versions older than these, then please use the standard Export functionality, selecting all the data elements, or folders of elements, to export and choosing either CLC or zip format as the export format. Further information about this is provided in section 6.6.5.

**6.6.7 Export history**

Each data element in the Workbench has a history. The history information includes things like the date and time data was imported or an analysis was run, the parameters and values set, and where the data came from. For example, in the case of an alignment, one would see the sequence data used for that alignment listed. You can view this information for each data element by clicking on the Show History view ( ) at the bottom of the viewing area when a data element is open in the Workbench.

This history information can be exported to a pdf document or to a CSV file. To do this:

- (Optional, but preferred) Select the data element (like an alignment) in the **Navigation Area**.
- Start up the exporter tool via the Export button in the toolbar or using the **Export** option under the File menu.
- Select the **History PDF** or History CSV as the format to export to (figure 6.31).
- Select the data to export, or confirm the data to export if it was already selected via the **Navigation Area**.
- Edit any parameters of interest, such as the Page Setup details, the output filename(s) and whether or not compression should be applied (figure 6.32).
- Select where the data should be exported to.
- Click on the button labeled **Finish**.
6.6.8 Backing up data from the CLC Workbench

Regular backups of your data are advisable.

The data stored in your CLC Workbench is in the areas defined as CLC Data Locations. Whole data locations can be backed up directly (option 1) or, for smaller amounts of data, you could export the selected data elements to a zip file (option 2).

Option 1: Backing up each CLC Data Location

The easiest way for most people to find out where their data is stored is to put the mouse cursor over the top level directories, that is, the ones that have an icon like ( ), in the Navigation Area of the Workbench. This brings up a tool tip with the system location for that data location.

To back up all your CLC data, please ensure that all your CLC Data Locations are backed up.

Here, if you needed to recover the data later, you could put the data folder from backup as a data location in your Workbench. If the original data location is not present, then the data should be usable directly. If the original data location is still present, the Workbench will re-index the (new) data location. For large volumes of data, re-indexing can take some time.

Information about your data locations can also be found in an xml file called model_settings_300.xml. This file is located in the settings folder in the user home area. Further details about this file and how it pertains to data locations in the Workbench can be found in the Deployment Manual: http://resources.qiagenbioinformatics.com/manuals/workbenchdeployment/current/index.php?manual=Changing_default_location.html.

Option 2: Export a folder of data or individual data elements to a CLC zip file

This option is for backing up smaller amounts of data, for example, certain results files or a whole data location, where that location contains smaller amounts of data. For data that takes
up many gigabases of space, this method can be used, but it can be very demanding on space, as well as time.

Select the data items, including any folders, in the Navigation area of your Workbench and choose to export by going to:

File | Export

and choosing zip format.

The zip file created will contain all the data you selected.

**A note about compatibility** Internal compression of CLC data was introduced in CLC Genomics Workbench 12.0, CLC Main Workbench 8.1 and CLC Genomics Server 11.0. If you are backing up data that may be used in software versions older than these, then please select the export option **Maximize compatibility with older CLC products**. Further information about this is provided in section 6.6.5

You can import the zip file into a Workbench by going to:

File | Import | Standard Import

and selecting "Automatic import" in the Options area.

The only data files associated with the **CLC Genomics Workbench** not within a specified data location are BLAST databases. It is unusual to back up BLAST databases as they are usually updated relatively frequently and in many cases can be easily re-created from the original files or re-downloaded from public resources. If you do wish to backup your BLAST database files, they can be found in the folders specified in the BLAST Database Manager, which is started by going to: Toolbox | BLAST | Manage BLAST databases

### 6.6.9 Export of tables

Tables can be exported in four different formats; CSV, tab-separated, Excel, or html.

When exporting a table in CSV, tab-separated, or Excel format, numbers with many decimals are printed in the exported file with 10 decimals, or in 1.123E-5 format when the number is close to zero.

Excel limits the number of hyperlinks in a worksheet to 66,530. When exporting a table of more than 66,530 rows, Excel will "repair" the file by removing all hyperlinks. If you want to keep the hyperlinks valid, you will need to export your data to several worksheets in batches smaller than 66,530 rows.

When exporting a table in html format, data are exported with the number of decimals that have been defined in the workbench preference settings. When tables are exported in html format from the server or using command line tools, the default number of exported decimals is 3.

The Excel exporters, the CSV and tab delimited exporters, and the HTML exporter have been extended with the ability to export only a sub-set of columns from the object being exported. Uncheck the option "Export all columns" and click next to see a new dialog window in which columns to be exported can be selected (figure 6.33).

You can choose to "Export the table as currently shown": This will export the table as shown in the active view, including any filtering, sorting, and dynamically added columns.
You can choose also choose which columns to export one by one, or choose a predefined subset of columns:

- **All**: will select all possible columns.
- **None**: will clear all preselected column.
- **Default**: will select the columns preselected by default by the software.
- **Last export**: will select all windows that were selected during the last export.
- **Active view (only if a table is currently open)**: the columns exported are the same than the ones selected in the Side Panel of the table.

After selecting columns, the user will be directed to the output destination wizard page.

**Note about decimals and Locale settings.** When exporting to CSV and tab delimited files, decimal numbers are formatted according to the Locale setting of the Workbench (see section 4.1). If you open the CSV or tab delimited file with spreadsheet software like Excel, you should make sure that both the Workbench and the spreadsheet software are using the same Locale.

### 6.7 Export graphics to files

**CLC Genomics Workbench** supports export of graphics into a number of formats. This way, the visible output of your work can easily be saved and used in presentations, reports etc. The **Export Graphics** function ([ ]) is found in the **Toolbar**.

**CLC Genomics Workbench** uses a WYSIWYG principle for graphics export: What You See Is What You Get. This means that you should use the options in the Side Panel to change how your data,
It is not possible to export graphics of elements directly from the Navigation Area. They must first be opened in a view in order to be exported. To export graphics of the contents of a view:

select tab of View | Graphics (🗜️) on Toolbar

This will display the dialog shown in figure 6.34.

![Figure 6.34: Selecting to export whole view or to export only the visible area.](image)

In the following dialog, you can choose to:

- Export visible area, or
- Export whole view

These options are available for all views that can be zoomed in and out. In figure 6.35 is a view of a circular sequence which is zoomed in so that you can only see a part of it.

![Figure 6.35: A circular sequence as it looks on the screen when zoomed in.](image)

When selecting Export visible area, the exported file will only contain the part of the sequence
that is visible in the view. The result from exporting the view from figure 6.35 and choosing Export visible area can be seen in figure 6.36.

On the other hand, if you select Export whole view, you will get a result that looks like figure 6.37. This means that the graphics file will also include the part of the sequence which is not visible when you have zoomed in.

For 3D structures, this first step is omitted and you will always export what is shown in the view (equivalent to selecting Export visible area).

Finally, choose a name and save location for the graphics file. Then you can either click Next or Finish, depending on what is available: clicking Next allows you to set further parameters for the graphics export, whereas clicking Finish will export using the parameters that you have set.
last time you made a graphics export in that file format (if it is the first time, it will use default parameters).

6.7.1 File formats

CLC Genomics Workbench supports the following file formats for graphics export:

<table>
<thead>
<tr>
<th>Format</th>
<th>Suffix</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Portable Network Graphics</td>
<td>.png</td>
<td>bitmap</td>
</tr>
<tr>
<td>JPEG</td>
<td>.jpg</td>
<td>bitmap</td>
</tr>
<tr>
<td>Tagged Image File</td>
<td>.tif</td>
<td>bitmap</td>
</tr>
<tr>
<td>PostScript</td>
<td>.ps</td>
<td>vector graphics</td>
</tr>
<tr>
<td>Encapsulated PostScript</td>
<td>.eps</td>
<td>vector graphics</td>
</tr>
<tr>
<td>Portable Document Format</td>
<td>.pdf</td>
<td>vector graphics</td>
</tr>
<tr>
<td>Scalable Vector Graphics</td>
<td>.svg</td>
<td>vector graphics</td>
</tr>
</tbody>
</table>

These formats can be divided into bitmap and vector graphics. The difference between these two categories is described below:

**Bitmap images**  In a bitmap image, each dot in the image has a specified color. This implies, that if you zoom in on the image there will not be enough dots, and if you zoom out there will be too many. In these cases the image viewer has to interpolate the colors to fit what is actually looked at. A bitmap image needs to have a high resolution if you want to zoom in. This format is a good choice for storing images without large shapes (e.g. dot plots). It is also appropriate if you don’t have the need for resizing and editing the image after export.

**Parameters for bitmap formats**  For bitmap files, clicking **Next** will display the dialog shown in figure 6.38.

![Figure 6.38: Parameters for bitmap formats: size of the graphics file.](image)

You can adjust the size (the resolution) of the file to four standard sizes:

- Screen resolution
- Low resolution
- Medium resolution
- High resolution
The actual size in pixels is displayed in parentheses. An estimate of the memory usage for exporting the file is also shown. If the image is to be used on computer screens only, a low resolution is sufficient. If the image is going to be used on printed material, a higher resolution is necessary to produce a good result.

**Vector graphics** Vector graphic is a collection of shapes. Thus what is stored is information about where a line starts and ends, and the color of the line and its width. This enables a given viewer to decide how to draw the line, no matter what the zoom factor is, thereby always giving a correct image. This format is good for graphs and reports, but less usable for dot plots. If the image is to be resized or edited, vector graphics are by far the best format to store graphics. If you open a vector graphics file in an application such as Adobe Illustrator, you will be able to manipulate the image in great detail.

Graphics files can also be imported into the Navigation Area. However, no kinds of graphics files can be displayed in CLC Genomics Workbench. See section 6.1.1 for more about importing external files into CLC Genomics Workbench.

**Parameters for vector formats** For PDF format, the dialog shown in figure 6.39 will sometimes appear after you have clicked finished (for example when the graphics use more than one page, or there is more than one PDF to export).

![Figure 6.39: Page setup parameters for vector formats.](image)

The settings for the page setup are shown. Clicking the **Page Setup** button will display a dialog where these settings can be adjusted. This dialog is described in section 5.2.

It is then possible to click the option “Apply these settings for subsequent reports in this export” to apply the chosen settings to all the PDFs included in the export for example.

The page setup is only available if you have selected to export the whole view - if you have chosen to export the visible area only, the graphics file will be on one page with no headers or footers.

**Exporting protein reports** It is possible to export a protein report using the normal Export function ( Depository ) which will generate a pdf file with a table of contents:

- **Click the report in the Navigation Area | Export ( Depository ) in the Toolbar | select pdf**

You can also choose to export a protein report using the Export graphics function ( Depository ), but in this way you will not get the table of contents.
6.8 Export graph data points to a file

Data points for graphs displayed along the sequence or along an alignment or mapping can be exported to a semicolon-separated text file (csv format). An example of such a graph is shown in figure 6.40, showing the conservation score of reads in a read mapping.

![Conservation graph](image)

Figure 6.40: A conservation graph displayed along mapped reads. Right-click the graph to export the data points to a file.

To export the data points for the graph, right-click the graph and choose Export Graph to Comma-separated File. Depending on what kind of graph you have selected, different options will be shown: If the graph is covering a set of aligned sequences with a main sequence, such as read mappings and BLAST results, the dialog shown in figure 6.41 will be displayed. These kinds of graphs are located under Alignment info in the Side Panel. In all other cases, a normal file dialog will be shown letting you specify name and location for the file.

![Export Graph to CSV dialog](image)

Figure 6.41: Choosing to include data points with gaps

In this dialog, select whether you wish to include positions where the main sequence (the reference sequence for read mappings and the query sequence for BLAST results) has gaps. If you are exporting e.g. coverage information from a read mapping, you would probably want to exclude gaps, if you want the positions in the exported file to match the reference (i.e. chromosome) coordinates. If you export including gaps, the data points in the file no longer corresponds to the reference coordinates, because each gap will shift the coordinates.

Clicking Next will present a file dialog letting you specify name and location for the file.

The output format of the file is like this:

```
"Position";"Value"
1;13
2;16
3;23
4;17
...
```
6.9 CLC Server data import and export

Data export from a CLC Server

When the Workbench is connected to a CLC Server, data held on the CLC Server can be exported to the system a CLC Workbench is running on, or it can be exported to an area the CLC Server has been configured to have access to. Such areas are called "Import/export" directories and these must be configured by your server administrator.

To export data to a place the CLC Workbench has access to, choose to run the export task on the Workbench. To export data to an "Import/Export" directory, choose to run the export task on the CLC Server, or Grid, as is appropriate for your setup.

Data import to a CLC Server

When connected to a CLC Server, data can be imported from "Import/export" directories that have been configured for the CLC Server. On some systems, data can also be imported from areas available to your CLC Workbench. When that is allowed, you will be able to choose where the files to be imported from are, either "On my local disk or a place I have access to" or "On the server or a place the server has access to", as shown in figure 6.42. The former refers to files available to the CLC Workbench, and the latter to files available to the CLC Server.

Not all server setups are configured to allow import from local disks, in which case, at least one "Import/export" directory will need to be configured by your server administrator to support import to the CLC Server.

6.10 Copy/paste view output

The content of tables (reports, folder lists, and sequence lists) can be copy/pasted into different programs, where it can be edited. CLC Genomics Workbench pastes the data in tabulator separated format in various programs in which the copy/paste can be applied. For simplicity, we include one example of the copy/paste function from a Folder Content view to Microsoft Excel.

Right click a folder in the Navigation Area and chooses Show | Content. The different elements saved in that folder are now listed in a table in the View Area. Select one or more of these elements and use the Ctrl + C (or ⌘ + C) command to copy the selected items.

See figure 6.43.
Then, in a new Excel document, right-click in the cell A1 and paste the items previously copied. The outcome might appear unorganized, but with a few operations the structure of the view in CLC Genomics Workbench can be produced. (Except the icons which are replaced by file references in Excel.)

Note that all tables can also be Exported directly in Excel format.

CLC Genomics Workbench offers different ways of searching and downloading online data. You must be online when initiating and performing the following searches.

7.1 Search for Sequences at NCBI

This section describes searches for sequences in GenBank - the NCBI database using Entrez (see https://www.ncbi.nlm.nih.gov/books/NBK3837/)

Download Search for Sequences at NCBI (Ctrl+B) or Ctrl + B (Cmd + B on Mac)

This opens the following view (figure 7.1).

The search view can be saved either using dragging the search tab and and dropping it in the Navigation Area or by clicking Save ( ). When saving the search, only the parameters are saved...
- not the results of the search. This is useful if you have a special search that you perform from time to time.

Even if you don’t save the search, the next time you open the search view, it will remember the parameters from the last time you did a search.

### 7.1.1 NCBI search options

Conducting a search in the NCBI Database from CLC Genomics Workbench corresponds to conducting the search on NCBI’s website, while having the results available and ready to work with straight away.

You can choose whether you want to search for nucleotide sequences, protein sequences or EST databases.

As default, CLC Genomics Workbench offers one text field where the search parameters can be entered. Click **Add search parameters** to add more parameters to your search. The search is a "and" search, meaning that when adding search parameters to your search, you search for both (or all) text strings rather than "any" of the text strings.

The following parameters can be added to the search:

- **All fields** Searches in all parameters in the NCBI database at the same time. It also provide an opportunity to search to parameters which are not listed in the dialog (e.g., CD9 NOT homo sapiens).
- **Organism**
- **Definition/Title**
- **Modified Since** Choose one option from the drop-down menu, between 30 days and 10 years.
- **Gene Location** Choose from Genomic DNA/RNA, Mitochondrion, or Chloroplast.
- **Molecule** Choose from Genomic DNA/RNA, mRNA or rRNA.
- **Sequence Length** enter a number for a maximum or minimum length of the sequence.
- **Gene Name**
- **Accession**
You can append a wildcard character by checking the checkbox at the bottom. This means that you only have to enter the first part of the search text, e.g., searching for "genom" will find both "genomic" and "genome".

A "Feature Key" option is available in GenBank when searching for nucleotide sequences: writing gene[Feature key] AND mouse will generate hits for one or more genes and where 'mouse' appears somewhere in GenBank file. For more information about how to use this syntax, see http://www.ncbi.nlm.nih.gov/books/NBK3837/

When you are satisfied with the parameters you have entered, click **Start search**. When conducting a search, no files are downloaded. Instead, the program produces a list of links to the files in the NCBI database. This ensures a much faster search.

### 7.1.2 Handling of NCBI search results

The search result is presented as a list of links to the files in the NCBI database. The **View** displays 50 hits at a time. This can be changed in the **Preferences** (see chapter 4). More hits can be displayed by clicking the **More...** button at the bottom right of the **View**.

Each sequence hit is represented by text in three columns:

- Accession.
- Description.
- Modification date.
- Length.

It is possible to exclude one or more of these columns by adjust the View preferences for the database search view. Furthermore, your changes in the View preferences can be saved. See section 4.6.

Several sequences can be selected, and by clicking the buttons in the bottom of the search view - or right clicking on the selected sequence(s) - you can do the following:

- **Download and Open** opens the sequence in a new view.
- **Download and Save** lets you choose location for saving sequence.
- **Open at NCBI** opens an internet browser and displays the sequence on NCBI’s web page.

Double-clicking a hit will download and open the sequence. The hits can also be downloaded into the **View Area** or the **Navigation Area** from the search results by drag and drop or copy/paste.

Search results are downloaded before they are saved. Downloading and saving several files may take some time. However, since the process runs in the background (displayed in the **Status bar**) it is possible to continue other tasks in the program. Like the search process, the download process can be stopped. This is done in the **Toolbox** in the **Processes** tab.
7.2 Search for PDB Structures at NCBI

This section describes searches for three dimensional structures from the NCBI structure database http://www.ncbi.nlm.nih.gov/Structure/MMDB/mmdb.shtml. For manipulating and visualization of the downloaded structures see section 13.2.

The NCBI search view is opened in this way:

- Download | Search for PBD Structures at NCBI ( )
- or Ctrl + B ( on Mac)

This opens the view shown in figure 7.2:

![The structure search view.](image)

---

7.2.1 Structure search options

Conducting a search in the NCBI Database from CLC Genomics Workbench corresponds to conducting search for structures on the NCBI’s Entrez website. When conducting the search from CLC Genomics Workbench, the results are available and ready to work with straight away.

As default, CLC Genomics Workbench offers one text field where the search parameters can be entered. Click Add search parameters to add more parameters to your search.

**Note!** The search is a "AND" search, meaning that when adding search parameters to your search, you search for both (or all) text strings rather than "any" of the text strings.

You can append a wildcard character by clicking the checkbox at the bottom. This means that you only have to enter the first part of the search text, e.g. searching for "prot" will find both "protein" and "protease".
The following parameters can be added to the search:

- **All fields.** Text, searches in all parameters in the NCBI structure database at the same time.
- **Organism.** Text.
- **Author.** Text.
- **PdbAcc.** The accession number of the structure in the PDB database.

The search parameters are the most recently used. The All fields allows searches in all parameters in the database at the same time. All fields also provide an opportunity to restrict a search to parameters which are not listed in the dialog. E.g. writing 'gene[Feature key] AND mouse' in All fields generates hits in the GenBank database which contains one or more genes and where 'mouse' appears somewhere in GenBank file. NB: the 'Feature Key' option is only available in GenBank when searching for nucleotide structures. For more information about how to use this syntax, see [http://www.ncbi.nlm.nih.gov/entrez/query/static/help/Summary_Matrices.html#Search_Fields_and_Qualifiers](http://www.ncbi.nlm.nih.gov/entrez/query/static/help/Summary_Matrices.html#Search_Fields_and_Qualifiers)

When you are satisfied with the parameters you have entered click Start search.

**Note!** When conducting a search, no files are downloaded. Instead, the program produces a list of links to the files in the NCBI database. This ensures a much faster search.

### 7.2.2 Handling of NCBI structure search results

The search result is presented as a list of links to the files in the NCBI database. The View displays 50 hits at a time (can be changed in the Preferences (see chapter 4). More hits can be displayed by clicking the More... button at the bottom right of the View.

Each structure hit is represented by text in three columns:

- Accession.
- Description.
- Resolution.
- Method.
- Protein chains
- Release date.

It is possible to exclude one or more of these columns by adjust the View preferences for the database search view. Furthermore, your changes in the View preferences can be saved. See section 4.6.

Several structures can be selected, and by clicking the buttons in the bottom of the search view, you can do the following:
• **Download and open.** Download and open immediately.

• **Download and save.** Download and save lets you choose location for saving structure.

• **Open at NCBI.** Open additional information on the selected structure at NCBI’s web page.

Double-clicking a hit will download and open the structure. The hits can also be copied into the **View Area** or the **Navigation Area** from the search results by drag and drop, copy/paste or by using the right-click menu as described below.

**Drag and drop from structure search results**

The structures from the search results can be opened by dragging them into a position in the **View Area**.

**Note!** A structure is not saved until the **View** displaying the structure is closed. When that happens, a dialog opens: Save changes of structure x? (Yes or No).

The structure can also be saved by dragging it into the **Navigation Area**. It is possible to select more structures and drag all of them into the **Navigation Area** at the same time.

**Download structure search results using right-click menu**

You may also select one or more structures from the list and download using the right-click menu (see figure 7.3). Choosing **Download and Save** lets you select a folder or location where the structures are saved when they are downloaded. Choosing **Download and Open** opens a new view for each of the selected structures.

![Figure 7.3: By right-clicking a search result, it is possible to choose how to handle the relevant structure.](image)

The selected structures are not downloaded from the NCBI website but is downloaded from the RCSB Protein Data Bank [http://www.rcsb.org/pdb/home/home.do](http://www.rcsb.org/pdb/home/home.do) in PDB format.

**Copy/paste from structure search results**

When using copy/paste to bring the search results into the **Navigation Area**, the actual files are downloaded.

To copy/paste files into the **Navigation Area**:

| select one or more of the search results | Ctrl + C (⌘ + C on Mac) |
| or folder in the Navigation Area | Ctrl + V |
Note! Search results are downloaded before they are saved. Downloading and saving several files may take some time. However, since the process runs in the background (displayed in the Status bar) it is possible to continue other tasks in the program. Like the search process, the download process can be stopped. This is done in the Toolbox in the Processes tab.

7.2.3 Save structure search parameters

The search view can be saved either using dragging the search tab and and dropping it in the Navigation Area or by clicking Save ( ). When saving the search, only the parameters are saved - not the results of the search. This is useful if you have a special search that you perform from time to time.

Even if you don’t save the search, the next time you open the search view, it will remember the parameters from the last time you did a search.

7.3 Search for Sequences in UniProt (Swiss-Prot/TrEMBL)

This section describes searches in UniProt and the handling of search results. UniProt is a global database of protein sequences.

The UniProt search view (figure 7.4) is opened in this way:

![The UniProt search view.](image)

7.3.1 UniProt search options

Conducting a search in UniProt from CLC Genomics Workbench corresponds to conducting the search on UniProt’s website. When conducting the search from CLC Genomics Workbench, the results are available and ready to work with straight away.

Above the search fields, you can choose which database to search:
• **Swiss-Prot** This is believed to be the most accurate and best quality protein database available. All entries in the database have been curated manually and data are entered according to the original research paper.

• **TrEMBL** This database contains computer annotated protein sequences, thus the quality of the annotations is not as good as the Swiss-Prot database.

As default, **CLC Genomics Workbench** offers one text field where the search parameters can be entered. Click **Add search parameters** to add more parameters to your search.

**Note!** The search is a "and" search, meaning that when adding search parameters to your search, you search for both (or all) text strings rather than "any" of the text strings.

You can append a wildcard character by checking the checkbox at the bottom. This means that you only have to enter the first part of the search text, e.g. searching for "genom" will find both "genomic" and "genome".

The following parameters can be added to the search:

- **All fields**. Text, searches in all parameters in the UniProt database at the same time.
- **Organism**. Text.
- **Description**. Text.
- **Created Since**. Between 30 days and 10 years.
- **Feature**. Text.

The search parameters listed in the dialog are the most recently used. The **All fields** allows searches in all parameters in the UniProt database at the same time.

When you are satisfied with the parameters you have entered, click **Start search**.

**Note!** When conducting a search, no files are downloaded. Instead, the program produces a list of links to the files in the UniProt database. This ensures a much faster search.

### 7.3.2 Handling of UniProt search results

The search result is presented as a list of links to the files in the UniProt database. The **View** displays 50 hits at a time (can be changed in the **Preferences** (see chapter 4). More hits can be displayed by clicking the **More...** button at the bottom right of the **View**. More hits can be displayed by clicking the **More...** button at the bottom left of the **View**.

Each sequence hit is represented by text in three columns:

- Accession
- Name
- Description
- Organism
• Length.

It is possible to exclude one or more of these columns by adjust the View preferences for the database search view. Furthermore, your changes in the View preferences can be saved. See section 4.6.

Several sequences can be selected, and by clicking the buttons in the bottom of the search view, you can do the following:

• Download and open, does not save the sequence.
• Download and save, lets you choose location for saving sequence.
• Open at UniProt, searches the sequence at UniProt’s web page.

Double-clicking a hit will download and open the sequence. The hits can also be copied into the View Area or the Navigation Area from the search results by drag and drop, copy/paste or by using the right-click menu as described below.

Drag and drop from UniProt search results

The sequences from the search results can be opened by dragging them into a position in the View Area.

Note! A sequence is not saved until the View displaying the sequence is closed. When that happens, a dialog opens: Save changes of sequence x? (Yes or No).

The sequence can also be saved by dragging it into the Navigation Area. It is possible to select more sequences and drag all of them into the Navigation Area at the same time.

Download UniProt search results using right-click menu

You may also select one or more sequences from the list and download using the right-click menu. Choosing Download and Save lets you select a folder or location where the sequences are saved when they are downloaded. Choosing Download and Open opens a new view for each of the selected sequences.

Copy/paste from UniProt search results

When using copy/paste to bring the search results into the Navigation Area, the actual files are downloaded from UniProt.

To copy/paste files into the Navigation Area:

   select one or more of the search results | Ctrl + C (⌘ + C on Mac) | select location or folder in the Navigation Area | Ctrl + V

Note! Search results are downloaded before they are saved. Downloading and saving several files may take some time. However, since the process runs in the background (displayed in the Toolbox under the Processes tab) it is possible to continue other tasks in the program. Like the search process, the download process can be stopped, paused, and resumed.
7.3.3 Save UniProt search parameters

The search view can be saved either using dragging the search tab and and dropping it in the Navigation Area or by clicking Save ( ). When saving the search, only the parameters are saved - not the results of the search. This is useful if you have a special search that you perform from time to time.

Even if you don’t save the search, the next time you open the search view, it will remember the parameters from the last time you did a search.

7.4 SRA search

This section describes searches in SRA and the handling of search results. SRA is an NCBI maintained database of NGS data.

The SRA search view (figure 7.5) is opened in this way:

Download | Search for Reads in SRA (

Figure 7.5: The SRA search view.

The tool queries the database with SRA accession number (see in figure 7.5) or various entries such as “hindgut” or ”genometrakr”. It is also possible to look for entries with certain properties, and to form more refined queries such as “paired-end RNA-Seq data from an Illumina HiSeq2500”.

7.4.1 SRA search options

Search parameters Different types of search are available from a drop-down menu on the left hand side of the search bar.

Some special types are:

- **Modification/Publication date** This allows the narrowing of results to a particular range of dates specified as [MM] [YYYY]. For example 08 2016 to 08 2016 returns results published from the first day in August 2016 to the last day in August 2016.
• **Strategy** Provides an additional drop-down list of types of experiments e.g., RNA-Seq, ChIP-Seq, etc.

• **Library Selection** Provides an additional drop-down list of known library preparation methods, e.g. Poly(A) and Size fractionation.

• **Platform** Provides an additional drop-down list of NGS sequencing platforms e.g., Illumina, Ion Torrent. Note that download of data from some platforms such as Complete Genomics is not supported.

• **Instrument** Provides an additional drop-down list of individual NGS sequencing machines e.g., HiSeq X Ten, Ion Torrent PGM.

• **Paired Status** Choose between paired end and single end runs.

• **Availability** Choose between dbGaP or public. dbGaP refers to confidential data that can be searched through the tool and accessed upon request at NCBI.

• **PubMed** Choose between "has abstract" or "has full-text article" to find results that have a PubMed abstract or entire publication available.

Any number of search parameters may be added to refine a search, for example to construct a query for "paired-end RNA-Seq data from an Illumina HiSeq2500", but the return search must satisfy every search parameter. In other words, search parameters work as "A and B" and not as "A or B". In consequence, searches performed with two platform parameters for example "Platform = Illumina and Platform = Ion Torrent" will not return any results.

Note also that searches rely on metadata provided by the depositor of the SRA runs. This means that if, for example, an RNA-Seq run was not annotated as being RNA-Seq during submission, it won’t be returned by a search for "Strategy = RNA-Seq".

Finally, the search tool uses NCBI’s e-utilities, which occasionally experience downtime. If no searches return any results, check [https://www.ncbi.nlm.nih.gov/sra/](https://www.ncbi.nlm.nih.gov/sra/) to see the status of the service.

### 7.4.2 SRA search output

The search results are displayed with one run per line. Each Run Accession is a hyperlink to the NCBI webpage for the run, where additional information may be found, such as the distribution of nucleotide quality scores and links to external resources. On the right hand side of the search table, a "SRA Preview" panel shows the title and abstract associated to the selected run when available.

When looking for a specific run using the run SRA accession number, the tool will output the run that was searched and may also list additional runs that were submitted as part of the same experiment. In any case, it is safest to perform a new search specifically for the study to make sure the tool retrieves all possible runs. Right-click on a row to get a list of possible searches based on the selected run (figure 7.6), for example searching for more runs from the same sample, experiment or organism.

By default, the tool will output a maximum of 50 runs. The "more..." button below the table retrieves additional search results when the search exceeds 50 runs. The number of additional results returned can be controlled in Edit | Preferences | General | Number of hits (NCBI/Uniprot).
The "Total number of experiments" at the bottom of the search table reports how many experiments were retrieved, and not how many runs are listed in the table.

At the bottom of the table, the button "Show Metadata for Selection" will create a metadata table containing sample specific information for the selected run(s). The first columns of the metadata table contain the same database identifiers as in the Search Table. The last columns recover sample details associated with the biosample. The list of all metadata available for the selected run is located in the right hand side panel of the table. This functionality is especially useful when selecting external data for use in a meta-analysis. For example, if your analysis is for a particular cancer type, and controls for the subject’s age and gender, the "Show Metadata for Selection" facilitates the search for other datasets where the same metadata is available.

### 7.4.3 Downloading reads and metadata from SRA

Click on **Download Reads and Metadata** to save reads and their associated data. The data is saved in a metadata table and can be later associated to the reads for use in downstream analysis, for example to define factors for differential expression in the Differential Expression for RNA-Seq tool. Should the metadata table later be deleted, the "Show Metadata for Selection" button can be used to quickly recover a copy without having to re-download all the runs.

The Download Reads and Metadata wizard offers the following options:

**Import Options** (figure 7.7)
As with other NGS reads importers, it is possible to discard read names and/or quality scores to save space.

- "Download size" is the size of the .sra files that will be downloaded. Note that in some cases, the actual download may be up to 1GB larger than stated, as .sra files can be reference-compressed, meaning that a copy of the genome must also be retrieved before the file can be converted into fastq and imported into the workbench.

- "Estimated free disk space required during download" is a conservative estimate for the total free disk space required to download the selected runs. This is the "Estimated final size on disk" + the size of the largest single run in FASTQ format + the size of the largest single run in SRA format.

- "Estimated final size on disk" is an estimate of the total size of the files after they have been imported into the workbench.

**Edit Paired End Settings** (figure 7.8)

![Figure 7.8: The Download Reads and Metadata Edit Paired End Settings dialog.](image)

This dialog appears for all runs marked as being Paired (Paired column contains "Yes").

**Read orientation** is always guessed to be "Forward Reverse" unless otherwise stated.

**Minimum distance** and **Maximum distance** depend on how much data the depositor supplied with the runs. They are allowed to supply an "Insert Size" and an "Insert Deviation".

- If no insert size is supplied, we use defaults of 1 for minimum and 1,000 for maximum.

- If an insert size is supplied, we make the following calculation:
  
  \[
  \text{Mindistance} = \text{insertsize} - 5 \times \text{insertdeviation} \\
  \text{Maxdistance} = \text{insertsize} + 5 \times \text{insertdeviation}
  \]

  - If no deviation is supplied, we estimate this to be \(0.1 \times \text{insertsize}\) and perform the same calculation as above.

When possible, we generally recommend that SRA data be used in subsequent analyses with the "Auto paired end distance detection" option enabled as the quality of deposited information is low. For example, some depositors report insert size including the length of the reads, and some excluding the length of the reads.
7.4.4 How reads are downloaded

SRA reads are downloaded in the ".sra" format using the NCBI SRA-toolkit. A .sra file is typically 2.5x smaller than an equivalent zipped fastq file. Download uses the NCBI 'prefetch' utility, and the resulting file is read into the workbench using 'fastq-dump'.

Sometimes runs in SRA cannot be downloaded. The affected runs are listed in a Problems panel together with a description of the problem. It is still possible to download the remaining runs.

The most common problems are:

- "The selected SRA reads contain no spots, and cannot be imported in the workbench.": The run has no associated sequencing data.
- "The selected SRA reads are dbGaP restricted.": For data protection reasons, you must request access to these reads. Requests and download cannot happen within the workbench, but you can follow the procedures here: http://www.ncbi.nlm.nih.gov/books/NBK5295/.
- "The selected SRA reads are made with an unsupported sequencing platform.": For example, Complete Genomics reads consist of eight regions separated by gaps of variable lengths, and should be analyzed by specialist tools.

We support download of reads via the commercial FASP protocol from Aspera. In our testing, Aspera download is up to 10x faster than a normal http download.

To enable this functionality, you have to download the Aspera Connect software from http://downloads.asperasoft.com/connect2/.

On Windows, choose to do a "Custom" install and choose to "Install for all users of this machine". You can then test if the installation worked by downloading a small file. The log (accessible from the Processes tab) will include the line "Downloading via fasp" if everything worked.

It is possible to change the Aspera options using Preferences | Advanced | SRA Download.

The following options are available:

- **Use Aspera when available** Per default, Aspera is automatically used if installed. This option makes it possible to disable Aspera.
- **Limit Aspera download speeds to [ ] Mb/s (Mac and Linux only)** Using Aspera may take up a lot of network resources. Use this option to specify a maximum download speed (in megabit per second). Note that this option is only available on Mac and Linux. For Windows users, it is possible to limit the maximum download speed by modifying the aspera.conf file, which can be found in C:\Program Files (x86)\Aspera\Aspera Connect\etc. See http://download.asperasoft.com/download/docs/csrv/3.3.4/linux/html/index.html and http://download.asperasoft.com/download/docs/csrv/3.3.4/linux/html/fasp/setting-global-bandwidth.html for more details.

7.5 Sequence web info

CLC Genomics Workbench provides direct access to web-based search in various databases and on the Internet using your computer’s default browser. You can look up a sequence in
the databases of NCBI and UniProt, search for a sequence on the Internet using Google and search for Pubmed references at NCBI. This is useful for quickly obtaining updated and additional information about a sequence.

The functionality of these search functions depends on the information that the sequence contains. You can see this information by viewing the sequence as text (see section 11.5). In the following sections, we will explain this in further detail.

The procedure for searching is identical for all four search options (see also figure 7.9):

Open a sequence or a sequence list | Right-click the name of the sequence | Web Info ( ) | select the desired search function

Figure 7.9: Open webpages with information about this sequence.

This will open your computer’s default browser searching for the sequence that you selected.

**Google sequence** The Google search function uses the accession number of the sequence which is used as search term on http://www.google.com. The resulting web page is equivalent to typing the accession number of the sequence into the search field on http://www.google.com.

**NCBI** The NCBI search function searches in GenBank at NCBI (http://www.ncbi.nlm.nih.gov) using an identification number (when you view the sequence as text it is the "GI" number). Therefore, the sequence file must contain this number in order to look it up at NCBI. All sequences downloaded from NCBI have this number.

**PubMed References** The PubMed references search option lets you look up Pubmed articles based on references contained in the sequence file (when you view the sequence as text it contains a number of "PUBMED" lines). Not all sequence have these PubMed references, but in this case you will see a dialog and the browser will not open.

**UniProt** The UniProt search function searches in the UniProt database (http://www.ebi.uniprot.org) using the accession number. Furthermore, it checks whether the sequence was indeed downloaded from UniProt.

**Additional annotation information** When sequences are downloaded from GenBank they often link to additional information on taxonomy, conserved domains etc. If such information is available for a sequence it is possible to access additional accurate online information. If the
db_xref identifier line is found as part of the annotation information in the downloaded GenBank file, it is possible to easily look up additional information on the NCBI web-site.

To access this feature, simply right click an annotation and see which databases are available. For tracks, these links are also available in the track table.

The ready-to-use workflows rely on the presence of particular reference data sets. The References management tool (figure 8.1) in the workbench makes it easy to download the necessary data ahead of time, and to create custom sets when needed.

The References management tool (figure 8.1) offers an easy way of retrieving popular reference data sources such as genes, variant annotations and genome sequences as tracks.

The total size of the reference data you can download can vary and is indicated when selecting the elements to download. The amount of time it will take to download this data depends on your network connection, but it can take several hours on slower connections.

Where reference data is downloaded from Data download using the Download Genomes comes from public repositories such as Ensembl, NCBI, UCSC. This type of data is not provided or hosted by QIAGEN. The workbench only provides an easy way to retrieve data that should otherwise have been downloaded and imported. The list of organisms is dynamically updated by QIAGEN independently of Workbench versions, so you will always see the most recent list of organisms. If you do not find the organism you are looking for, there is always the possibility to download and import the data using the Import tools.

The QIAGEN Sets tab allows you to download curated Reference Data Sets directly from a QIAGEN reference data repository. The location of the repository can be changed in the Edit | Preferences | Advanced as shown in figure 8.2.
CHAPTER 8. REFERENCES MANAGEMENT

Figure 8.1: Click on the References button and choose the QIAGEN Sets tab to find and download reference data; Custom Sets to customize reference data sets; and Imported Data to import your own reference data.

Figure 8.2: The location where reference data is downloaded from can be seen in the Workbench Preferences.

Unless you are in the special circumstance that your system administrator has decided to mirror this data locally and wishes you to use that mirror of the data, you should **not** change this setting.

**Where reference data is downloaded to** The reference data that is downloaded will be stored in a folder called **CLC_References**. When the **CLC Genomics Workbench** is installed, such a folder is created on your file system under your home area. This folder is specified within the workbench as a reference location.

On the right hand side of the Reference manager, you can use the drop-down menu to choose where you intend to manage the reference data. If you choose "Locally", the Download and Delete buttons will work on the local reference data. If you choose "On Server" (only available if
you are connected to a server), the buttons will work on the reference data on the server you are connected to (figure 8.3).

**Figure 8.3:** Reference data can be available locally or on the server.

When working locally, you can also check how much free space is available for the Reference folder on your local disk.

When working on a Server, a drop down menu situated below the list of existing element to download for a particular species in the **Download Genomes** tab will let you choose which server or grid node to use for the download.

When the option "On Server" is selected and you are working with a server configured with grid nodes, then a drop down menu listing the available grid presets will be present to the left of the **Download** button when working with data available under the Download Genomes tab. Select the correct grid before pressing the **Download** button.

**Changing the reference data location** You can specify a different location to download reference data to. This is recommended if you do not have enough space in the area the workbench designates as the reference data location by default. To change the reference data location from within the **Navigation Area:**

- **Right-click on the folder "CLC_References" | Choose "Location" | Choose "Specify Reference Location"**

The new folder will also be called CLC_References, but will be located where you specify.

In more detail, this action results in the following:

- A folder called CLC_References is created in the location you specified, if a folder of this name did not already exist.
- The workbench sets this new location as the place to download reference data to and the place the ready-to-use workflows should look for reference data.

This action does **not:**

- Remove the old CLC_References folder.
- Remove the contents of the old CLC_References folder, such as previously downloaded data.

If you have previously downloaded data into the CLC_References folder with the old location, you will need to use standard system tools to delete this folder and/or its contents. If you would like to keep the reference data from the old location, you can move it, using standard system tools, into the new CLC_References folder that you just specified. This would save you needing to download it again.

**Note!** If you run out of space, and realize that the CLC_References should be stored somewhere else, you can do this by choosing a new location, then manually moving the already downloaded data.
files to that new location, and restarting the workbench. The "downloaded references" file will then be updated with all the new references.

Reference data for non-networked systems CLC Genomics Workbench may be installed on computers that have no access to the external network. In that case, please proceed with the following steps to import reference data to the non-networked workbench:

1. Install CLC Genomics Workbench on a machine with access to the external network.

2. Download an evaluation license via the Workbench License Manager. If you have problems obtaining an evaluation license this way, please write to us at ts-bioinformatics@qiagen.com.

3. Use the Reference Data Manager on the networked Workbench to download the reference data of interest. By default, this would be downloaded to a folder called CLC_References.

4. When the download is completed, copy the CLC_References folder and all its contents to a location where the machines with the CLC software installed can access it.

5. Get the software to refer to that folder for reference data: in the Navigation Area of the non-networked Workbench, right click on the CLC_References, and choose the option "Specify Reference Location...". Choose the folder you imported from the networked Workbench and click Select.

You can then access reference data using the Reference Data manager.

8.1 Download Genomes

In the Download Genomes tab, you can access genomes and associated genomic data such as annotations and known variants (figure 8.4). The data is not provided or hosted by QIAGEN. The workbench only provides an easy way to retrieve data that should otherwise have been downloaded and imported.

The list of organisms is dynamically updated by QIAGEN independently of Workbench versions, so you will always see the most recent list of organisms. Select the organism of your choice to see what is available for download, and check the elements you want to include in the downloading process (the size of the download file is updated with each selected element). Please note that the file size displayed in the setup window for the Download Genomes tool refers to the size of the compressed text files, which the tool is retrieving from the provider’s depository. The size of the track objects will be, after decompression and conversion from text to the .clc track format, larger.

The reference sequence will be downloaded automatically from Ensembl. You can also choose to select an existing genome sequence track from your Navigation Area to initiate the download. In that case, the reference sequence has to match the genome definition built into the download tool. This means that the name and length of the chromosomes in your reference sequence have to match the genome definition of the tool.

All data downloaded with this tool will be tracks (either sequence tracks or various kinds of annotation tracks). The Ensemble human gene annotation download will produce various tracks describing the chromosomal positions of features such as exons, genes, untranslated region
(UTRs), transcripts, selenocysteines, coding sequences (CDSs) and mRNAs. The tracks be saved in a folder called "Genomes" in the CLC_References folder of the Navigation Area. Previous downloads are listed in the Reference Data Manager dialog, and can be deleted from there if needed (but note that this requires admin rights if the files are located on a server).

Which types of annotation are available for download is different from organism to organism and depends on the data sources that QIAGEN has included for download. Please note that for human data, a difference between the UCSC genome build and Ensembl/NCBI exists, which means that variants downloaded from UCSC will not be annotated on the mitochondrial genome when using this download tool. The Ensemble human gene annotation download will produce various tracks describing the chromosomal positions of features such as exons, genes, untranslated region (UTRs), transcripts, selenocysteines, coding sequences (CDSs) and mRNAs. UCSC Genome Browser available data include dbsnp variants and chromosome ideograms, also called a cytogenetic ideograms, i.e., a chromosome map with numbered banding patterns that shows the relationship between the two chromosome arms and the centromere (figure 8.5).

8.2 QIAGEN Sets

The QIAGEN Sets Reference Data Library tab gives access to all the reference data used with the Biomedical Genomics Analysis plugin ready-to-use workflows and tutorials, as well as custom workflows. From the wizard you can download and configure the reference data.

In this tab, Reference Data Sets and Elements available for download are listed to the left of the wizard under 6 headers (see figure 8.6). Each Reference Data Set is a collection of Reference Data Elements. Each Reference Data Element is assigned a Workflow Role when part of a Reference Data Set. The Workflow Role of a Reference Data Element determines which inputs it will be used for when running a configured workflow with the given Reference Data Set.

Downloading sets will automatically download the elements the set is made of, but you can also download elements individually under the Reference Data Elements folder. Tutorial Reference Data Sets are made to use with some of our tutorials (http://www.qiagenbioinformatics.com/support/tutorials/) (beware that some are chromosome-
specific). The **Previous Reference Data Sets** folder contains older versions of the Reference Data Sets that have been replaced with updated ones in the Reference Data Sets folder.

![Figure 8.5: The ideogram is particularly useful when used in combination with other tracks in a track list. In this figure the ideogram is highlighted with a red box.](image)

![Figure 8.6: Reference data (Data Sets and Elements) available for download are sorted in 6 different categories.](image)

Icons to the left of the listed names indicate whether you have already downloaded this data in your Reference folder (⊙) or not (⊙).

When selecting a reference set, you will see the size of the whole data set, as well as a table that recapitulates the elements included in the set with their version number and respective size.

Click on the **Download** button: Once the data is downloading, you can check the progress of the download, **Cancel**, **Pause** or **Resume** it (see figure 8.7).
The QIAGEN Sets wizard also offers a **Create Custom Set** button that allows you to create your own set of reference data starting from an existing data set (see section 8.3 for additional information on creating custom sets).

Note for the "1000 Genomes Project" (http://www.1000genomes.org/category/frequently-asked-questions/population) and "HapMap" (http://www.sanger.ac.uk/resources/downloads/human/hapmap3.html): These databases contain more than one reference data file, and the QIAGEN References Data Sets are initially configured with all populations available. You can specify which populations to use in the workflow wizard directly, or you can create a custom set that contains only the populations you want to work with.

The **Delete** button allows user to delete locally installed reference data. This can be used if you suspect that a downloaded reference is corrupt, and needs to be re-downloaded, or if you need to clean up space locally. Only administrators are able to delete reference data installed on the server.

The **Copy from server** / **Copy from workbench** button allows to copy locally a Reference Data Set already stored on the Server, and vice versa.

### 8.3 Custom Sets

The References Management offers a **Custom Sets** tab that allows you to store and generate your own sets of reference data (figure 8.8).

Custom Sets (a collection of chosen reference elements) can be used as reference data when running workflows:

- if the workflow inputs have been configured with workflow roles (see http://resources.qiagenbioinformatics.com/manuals/clcgenomicsworkbench/current/index.php?manual=Configuring_workflow_inputs.html. 

Figure 8.7: Download of reference data is ongoing.
• and the reference elements have been assigned matching workflow roles.

The Workflow Role of a Reference Data Element create the link between the workflow input and the reference data element in the custom set.

![The Custom Sets wizard.](image)

Figure 8.8: The Custom Sets wizard.

The principle of creating a custom Reference Data Set is to specify successively the different roles needed, followed by specifying the data fitting to the elements specified.

One way to create a custom reference data set is to click on Create. After naming the data set and providing a description for this data set, you can

• Select successively the roles that are needed by the workflow using the drop down menu.

• Create new roles by simply typing in the field a new role name as seen in figure 8.9. Custom roles are especially useful when working with complex workflows that include many different inputs.

![The Create Custom Sets dialog showing a newly created role, and the drop down menu of already existing roles.](image)

Figure 8.9: The Create Custom Sets dialog showing a newly created role, and the drop down menu of already existing roles.

• Use a pre-existing workflow to list roles needed: click on Create and then Add to match workflow ... (figure 8.10). You can then select an installed workflow (from the drop down list) or a workflow from the Navigation Area (to be specified in the "Custom workflow" field) for which roles have been assigned during configuration. The workflow roles specified in the workflow will then be listed here. The first line "Workflow role" can be checked/unchecked
as a way to select/deselect all items in the list. Once you have picked the items you wish to include in your custom data set, click **OK** to proceed.

Figure 8.10: Select the workflow for which you need a custom Reference Data Set.

Now all the needed reference roles are listed in the main window (figure 8.11). For each role, you will specify the relevant reference element by clicking on the Browse icon to the right of the field - or delete the particular role from the Reference Data Set by clicking on the cross icon.

Figure 8.11: Select the elements for each role included in your custom Reference Data Set.

There are two ways to find a particular element: by using the Navigation Area tab or from the Reference Data tab (figure 8.12). In the Navigation Area tab, the references elements are sorted by role, in organisms specific subfolders, in the CLC_References folder (local or on server). In the Reference Data tab, the elements are sorted by role in Data Sets specific folders, including custom data sets.

Note that it is only possible to select an element whose role is the one defined by the list; for example, when browsing for 1000_genomes_project files, it will not be possible to specify a genes track. However, it is possible to create new roles as needed: just type in the name of the custom role in the field and click Add element. There is no restriction on the type of file that can be selected for custom roles.
Once you are ready to save your custom data set, give it a name, and indicate in the description the workflow it is suitable for before clicking on OK. The custom set is now listed to the left side of the wizard. Saving a custom data set on a server is the most efficient way to share it with all other server users. Server admins can choose to lock or unlock reference data set on the server location so that the data sets cannot be deleted or modified.

### 8.3.1 Copy to References

When specifying an Element, it is recommended to use files that were previously saved in the CLC_References folder, but it is also possible to choose a file from any location in the Navigation Area. When using the last option, be aware that this file is not protected as read-only and may be subject to changes. To avoid this, click on "Copy to References" to save the Navigation Area element in the CLC_References file as read-only (figure 8.13).

Once the data has been copied to the CLC_References data set, the custom workflow will automatically refer to the file in the read-only folder rather than from the location in the Navigation Area that was originally specified.

For information about the additional functionalities on the Imported Data Sets, please see the section of the same name in the CLC Genomics Workbench manual.
8.3.2 Export a Custom Data Set

It is possible to export custom data set (figure 8.14). The export format is *cpc, and can be imported by anyone who has installed a workbench (even in Viewing Mode only).

Exporting a custom data set will export the different roles that are included in the data set. The export function can also export the data associated to the role, but it not always necessary. When the Reference Data Type is set to:

- QIAGEN reference data: the data is available in the QIAGEN Sets tab, so it is not necessary to include it in the export file, as it can be downloaded by the recipient of the exported file using the Reference Data Manager.
- Custom reference data: This reference data is not included in the QIAGEN repository, so it may have to be included in the export file to be shared with the recipient.
- Not reference data: A file that does not belong to the CLC_References folder has been chosen as part of the custom data set. This file needs to be imported as a reference (via the Copy to References button) and specified in the custom reference data from its location in the CLC_References folder to be exported.

When the export check box is unchecked, only the role will be exported. If the box is checked, the data associated with the role will also be exported. That way, it is possible to create small export files that only contain roles and custom elements, while the elements that are available in the QIAGEN Reference Sets list can be downloaded by the recipient of the exported file.

8.3.3 Import a Custom Data Set

It is possible to import custom data set *cpc from the Custom Sets tab (figure 8.15).

When importing, you are in fact importing a set of roles. In addition, you are also given options on how to handle the incoming data when present:
Download: The custom data set contains some QIAGEN reference data that was specified, but not exported. By leaving the status to Download, you will save the data directly from the QIAGEN repository to your CLC_References folder. This may take some time for particular elements.

None - already present: this means that the data specified in the custom data set is already saved in your own reference data.

Import: The custom data set includes some custom reference data that was exported together with the list of roles. Importing the data set will then also import the data and save it to a newly defined folder in the CLC_References read-only folder.

You can choose not to import or download the data attached to the roles included in the data set using the drop down menu option present for each role included in the reference data set. If you include data, you can check the progress of the import in the Processes tab of the Toolbox. Once the set is imported, you will find the custom elements in the "Imported" subfolder of the CLC_References folder.

### 8.4 Imported Data

The Imported Data tab enables you to import Data Sets or Elements in the read-only location of the CLC_References folder from two different locations:

- **Copy from the Navigation Area** allows you to select a folder in the Navigation Area for import into the CLC_References folder (for example reference data that was imported through the traditional Import function of the workbench and saved in a specific folder in the Navigation Area)

- **Import from file** allows you to specify a *.cpd data package on your computer for import into the CLC_References folder. A *.cpd file can be generated by exporting a data package as explained below.

It is possible to edit or add information to the data imported with the buttons above: Name of the dataset, Description, Author name, Author email, and Organization. For folders imported using the **Copy to References** button of the Customs Sets tab, the button **Finalize** can be used to add...
the above information (figure 8.16). Finalized imported data means that it is not possible to add additional elements to the imported folder.

Imported folders are listed in the view to the left, under the "Imported Reference Data" header. Upon selecting an imported Reference Data file, one can access the elements it contains by clicking Show in Navigation Area. It is also possible to Export such a file (as a *cpd file), or to Delete the folder (for server admin only if the data is on a server). Note that it is never possible to delete a CLC_References file through the Navigation Area as the folder is a read-only location.

8.4.1 Exporting reference data outside of the Reference Data Manager framework

This can be very useful when using the external applications, i.e., programs that are not part of the CLC workbench framework but that can be run using the same reference data.

To export a reference data set for external applications, you cannot use the Export button from the Reference Data Manager (that would export data set as CPD files), but the Export tool to export the data in the relevant format (VCF, FASTA, etc).

For example, if the Reference Data element "Clinvar" already has been exported, then there might be a folder called /homo_sapiens/clinvar/20131203 with the file Clinvar_20131203.vcf. If the export is invoked again, then the folder will contain two identical files with difference names: Clinvar_20131203.vcf and Clinvar_20131203.1.vcf. The second file will not be used.

No special permissions are required to export reference data, but administrator rights are required to delete reference data. If it becomes necessary to delete exported reference data, an administrator, super user, or some user with administrator rights, must do this. Deletion of exported data has to be done through the operation system, it cannot be done through the Workbench, nor the CLC server.

  9.3.3 Parameters for batch runs ............................... 199
  9.3.4 Running the analysis and organizing the results .... 199

This section describes how to run a tool using singles files as input, as well as how to handle and inspect results. We also review how to run tools using the batch mode when the option is enabled.

9.1 Running tools

All the analyses in the Toolbox are performed in a step-by-step procedure:

- Data elements to be used in the analysis are selected.
- Any configurations necessary for the tool to run are made.
- The results are opened or saved.

You can open a tool from the Toolbox by double clicking on its name in the Toolbox in the bottom left side of the Workbench, or by selecting it from the Toolbox menu at the top. You can also find tools quickly by clicking on the Launch button (Launch button) in the toolboar. Double click on the name of the tool in the table to launch it. If you enter a search term in the field at the top of the Quick launch window, tools with that term in their names or descriptions will be listed.
When you open a tool, a wizard pops up in the center of the View Area. Stepping through a succession of wizard steps, you will select the data to analyze, configure any analysis parameters, and specify how the results should be handled. You can navigate between wizard steps by clicking the buttons **Next** and **Previous** at the bottom of the window.

If you have logged into a **CLC Server** from your Workbench, you will first be asked to select whether the job should be run on the Workbench or submitted to the server. These choices, along with information about data selection and other considerations when launching tasks on a **CLC Server** are provided in section 9.2.1.

Generally, the first analysis configuration step involves selecting the data elements to be used as input. A view of your Navigation Area will be presented to you. That view will show data elements appropriate for use as input for that tool. Folders are also shown. For example, in figure 9.1 you can see a the Workbench Navigation Area (on the left) and a view of the same Navigation Area in the wizard (on top) for the Assemble Sequences tool. This tool only accepts nucleotide sequences and nucleotide sequence lists, so data elements of other types that can be seen in the Workbench Navigation Area, such as the one called "Read mapping", and the amino acid sequence ATP8a1, are not displayed in the wizard Navigation Area.

The data types that can be used as input for a given tool are described in the manual section about that tool. This documentation can be opened directly by clicking on the **Help** button in the bottom left corner of the launch wizard.

![Figure 9.1: You can select input files for the tool from the Navigation Area view presented on the left hand side of the wizard window.](image)

To indicate the data elements to be used in the analysis, either double click on them in the "Navigation Area" view on the left, or select them with a single click and then click on the right hand arrow. These items will then be listed in the "Selected elements" list on the right. If data elements of appropriate types were already selected in the Workbench Navigation Area before launching the tool, these will be automatically entered into the Selected elements list. To remove entries in that list, just double click on them or select them with a single click and then click on the left hand arrow.

When multiple elements are selected, most analysis tools will treat all those elements as a single input data set unless the "Batch" option at the bottom, has been selected. If that option is selected, then the tool will be run multiple times, once for each "batch unit", which may be a data element, or folder containing data elements or containing folders of elements. Batch processing is described in more detail in section 9.3.

Once the data of interest has been selected, click on **Next**. Depending on the tool, there may now be one or more steps for configuring analysis parameters. An example is shown in figure 9.2. Clicking on the **Reset** button resets all parameters in that step to their default values.
CHAPTER 9. RUNNING TOOLS, HANDLING RESULTS AND BATCHING

9.2 Handling results

Some tools can generate several outputs. If there is a choice of which ones to generate, you will be able to configure this in the final wizard step, called "Result handling". The kind of output files generated by a tool are described in the tool specific sections of the manual.

For tasks run on a Workbench (as opposed to a CLC Server) the "Result handling" window also allows you to decide whether you want to open or save your results.

- **Open.** This will open the result of the analysis in a view. This is the default setting.
- **Save** The results will be saved rather than opened. You will be prompted for where you wish the results to be saved (figure 9.3). You can save to an existing area or create a new folder to save the results into.

You may also have an option called "Open log". If checked, a window will open in the View area after the analysis has started and the progress of the job will be reported there line by line.

Click on the button labeled **Finish** to start the analysis.

If you chose the option to open the results, they will open automatically in one or several tabs in the View Area. The data will not have been saved at this point. The name of each tab is in bold,
appended with an asterisk to indicate this. There are several ways to save the results you wish to keep:

- Drag the tab to the relevant location in the Navigation Area.
- Select the tab and then use the key combination Ctrl + S (or ⌘ + S on macOS).
- Right click on the tab and choose "Save" from the context menu.
- Use the "Save" button in the Workbench toolbar.
- Go the the File menu and select the option "Save" or "Save As...".

If you chose to save the results, they will have been saved in the location specified. You can open the results in the Navigation Area directly after the analysis is finished. A quick way to find the results is to click on the little arrow to the right of the analysis name in the Processes tab and choose the option "Show results" or "Find Results", as shown in figure 9.4.

Figure 9.4: Find or open the analysis results by clicking on the little arrow to the right of the analysis name in the Processes tab and choosing the relevant item from the menu.

9.2.1 Running a tool on a CLC Server

When you launch an analysis from a Workbench that is logged into a CLC Server, you are offered the choice of where the analysis should be run, as shown in figure 9.5.

- **Workbench.** Run the analysis on the computer the CLC Workbench is running on.
- **Server.** Run the analysis using the CLC Server. For job node setups, analyses will be run on the job nodes.
- **Grid.** Only offered if the CLC Server setup has grid nodes. Here, jobs are sent from the master CLC Server to be run on grid nodes. The grid queue to submit to can be selected from the drop down list under the Grid option.

You can check the Remember setting and skip this step option if you wish to always use the selected option when submitting analyses that can be run on a CLC Server. If you select this option but later change your mind, just start up an analysis and click on the Previous button. The step with the options for where to run analyses will then be shown.
When launched a task to run on a CLC Server or on grid nodes, there are a few things to be aware of:

- You can only analyze data stored in CLC Server data areas. Thus only these data areas will be offered to select from when configuring an analysis.

- You have to save the analysis results. For a single analysis run on the Workbench, you can normally choose how to handle the results: Open or Save. Results from analyses performed on a CLC Server must be saved.

- After you have launched an analysis, it is submitted to the CLC Server to be handled. You can then close the Workbench or disconnect from the CLC Server if you wish. If an analysis finishes while your Workbench is closed or not connected to the CLC Server, you will see a notification about this when you next log in from the Workbench.

- When importing data into a CLC Server, the location of the data being imported affects when it is safe to close the Workbench or disconnect from the server. Further information about that can be found in section 2.3.

## 9.3 Batch processing

Batch processing refers to running an analysis multiple times, using different inputs for each analysis run. For example, if you have 10 sequence lists and wish to run 10 mapping analyses, one per sequence list, then these 10 analyses could be launched by setting up one batch job. When a job is run in batch mode, parameter settings stay the same for each run. It is just the inputs that are changed.

This section describes batch processing as it applies to most workbench tools and to workflows with a single input element.

Batching installed workflows with multiple input elements, where all input elements will be changed per batch, is done differently (see section 10.5).

### 9.3.1 Standard batch processing

Standard batch mode is activated by clicking the Batch checkbox in the dialog where the input data is selected (figure 9.6).

Unlike launching a single task, you can select a folder as well as, or instead of, individual data elements for the analysis.
A batch unit is the set of data that will be used as a single input set for a given run of an analysis. A given batch unit can consist of one or more data elements.

If a folder is selected as input to a batch analysis, each folder or data element directly under that folder will be considered a batch unit. This means:

- Each individual data element contained directly within the folder is a batch unit.
- Each subfolder directly within this folder is a batch unit, so all elements within a given subfolder will be considered as single input for the purposes of the analysis.
- Elements in any more deeply nested subfolders (e.g. subfolders of subfolders of the originally selected folder) will not be considered for the analysis.

### 9.3.2 Batch overview

The next Wizard step is the batch overview where you have the opportunity to refine the list of data that will be in each batch unit. For example, you could use this step to ensure that only trimmed sequence lists - and not all sequence lists - should be used for the analysis that is being setup.

The batch overview lists the batch units on the left and the contents of the selected batch unit on the right (figure 9.7).

![Batch overview](image)

**Figure 9.7:** Overview of the batch run. At the bottom right, the number of files to be analysed, summed across all batch units, is shown, 92 in this case.
In this example, the two sequences (pcDNA) are defined as separate batch units because they are located at the top level of the Cloning folder. Of the four subfolders of the Cloning folder initially selected, three are listed in this view. In each of these subfolders, any data elements that the analysis could use as input will be used unless action is taken at this point to exclude some of these. So all the elements in the subfolder “Cloning vector library” and shown on the right-hand side of the dialog will be included as part of a single analysis run.

Note that folders that do not contain any data that can be used by the tool being launched will not be shown in that dialog.

Including and excluding data elements in batch units There are three ways to refine the data elements that should be included in a batch unit, and thereby get taken forward into the analysis.

- **Use the fields labeled Only use elements containing and Exclude elements containing at the bottom of the batch overview** This refinement is done based on data element names. For example, only paired reads might be desired for the analysis, in which case, putting the text "paired" into the Only use elements containing field might be useful.

- **Remove a whole batch unit** Right-click on the batch unit to be removed and choose the option Remove Batch Unit.

- **Remove a particular data element from a batch unit** Right click on the element of a batch unit to be removed and choose the option Remove Element. This can be useful when filtering based on name, described in the first option, cannot be used to refine the batch units specifically enough.

9.3.3 Parameters for batch runs

The subsequent dialogs depend on the analysis being run and the data being input. Generally, one of the batch units will be specified as the parameter prototype and will then be used to guide the choices in the dialogs. By default, the first batch unit (marked in bold) is used for this purpose. This can be changed by right-clicking another batch unit and choosing the option Set as Parameter Prototype.

When launching tools normally (non-batch runs), the Workbench does much validation of inputs and parameters. When running in batch, this validation is not performed. This means that some analyses will fail if combinations of input data and parameters are not right. Therefore we recommend that batching is used when the batch units are quite homogenous in terms of the type and size of data.

9.3.4 Running the analysis and organizing the results

The last step in setting up a batch analysis is to choose where to save the outputs (figure 9.8). The options available are:

- **Save in input folder** Save all outputs into the same folder as the input data. If the batch units consisted of folders, then the results of each analysis would be saved into the folder with the data it was generated using. If the batch units were individual data elements, then all the results will be placed into the same folder as those input data elements.
CHAPTER 9. RUNNING TOOLS, HANDLING RESULTS AND BATCHING

Figure 9.8: Options for saving results when the tool was run in batch.

- **Save in specified location** Choose the folder where the outputs should be saved to, where when:
  - **Create subfolders per batch unit** is unchecked, all results for all batch units will be written to the specified folder.
  - **Create subfolders per batch unit** is checked, results for each batch unit will be written to a newly created subfolder of the selected folder. One subfolder is created per batch unit.

When the batch run is started, there will be one "master" process representing the overall batch job, and there will then be a separate process for each batch unit. The behavior this is different for Workbenches and Servers:

- On a Workbench, only one batch unit is run at a time. So when the first batch unit is done, the second will be started and so on. This avoids many parallel analyses that would draw on the same compute resources and slow down the computer.

- On a CLC Server, all the processes are placed in the queue, and the queue takes care of distributing the jobs. This means that if the server set-up includes multiple nodes, different batch unit analyses may be run in parallel.

To stop the whole batch run, stop the "master" process. From the Workbench, this can be done by finding the master process in the Processes tab in the bottom left hand corner. Click on the little triangle on the right hand side of the master process and choose the option **Stop**.

For some analyses, there is an extra option in the final step to create a log of the batch process. This log will be created in the beginning of the process and continually updated with information about the results. The log will either be saved with the results of the analysis or opened in a view with the results, depending on how you chose to handle the results.

The CLC Genomics Workbench provides a framework for creating, distributing, installing and running workflows. A workflow consists of a series of connected tools where the output of one tool is used as input for another tool. Once the workflow is set up, it can be installed (either in your own Workbench or it can be shared with colleagues and installed on a server). In that way it becomes possible to analyze lots of samples using the same standard pipeline, the same reference data and the same parameters.
This chapter will first explain how to create a new workflow, and next go into details about the installation and execution of a workflow.

Workflows created in the Workbench can also be installed on a CLC Genomics Server. For information about installing a workflow on the CLC Genomics Server, please see the user manual at http://www.qiagenbioinformatics.com/support/manuals/.

### 10.1 Creating a workflow

A workflow can be created by pressing the "Workflows" button (/button in the toolbar and then selecting "New Workflow..." (/button).

Alternatively, a workflow can be created via the menu bar:

File | New | Workflow (/button)

This will open a new view with a blank screen where a new workflow can be created.

#### 10.1.1 Adding workflow elements

First, click the Add Element (/button) button at the bottom (or use the shortcut Shift + Alt + E). This will bring up a dialog that lists the elements and tools, which can be added to a workflow (see figure 10.1).

Alternatively elements can be dragged directly from the Toolbox into the workflow. Only workflow enabled elements can be dropped in the workflow.

![Add Elements dialog](image)

Figure 10.1: Adding elements in the workflow.

Elements that can be selected in the dialog are mostly tools from the Toolbox. However, there
are two special elements on the list: the elements that are used for input and output. These are explained in section 10.1.7.

You can select more than one element in the dialog by pressing Ctrl (⌘ on Mac) while selecting. Click OK when you have selected the relevant tools. You can add more later on if you wish.

You will now see the selected elements in the editor (see figure 10.2).

![Figure 10.2: Read mapping and variant calling added to the workflow.](image)

Once added, you can move and rearrange the elements by dragging them with the mouse. To do this, click on part of the box containing the name of the element and then, keeping the mouse button depressed, drag the element to the desired position.
10.1.2 Configuring workflow inputs

There are two kinds of inputs in a workflow (figure 10.3):

- Primary inputs: these inputs vary every time the workflow is run. Primary inputs are shown with a light grey background in the workflow editor. An example of a primary input is the case variant track in the example below.

- Secondary inputs: these inputs are considered more constant. Secondary inputs could be reference data, or a set of controls to evaluate the case sample(s) against. Secondary inputs have a brown background in the workflow editor.

![Diagram of workflow inputs](image)

Figure 10.3: Selecting a particular file to configure the workflow with.

Secondary inputs can be configured to work in two different situations:

- When running the workflow without a Reference Data Set, or when running it with a reference data set that does not have a reference data element with the corresponding role.

- When running the workflow with a Reference Data Set. In this case, the Workflow Role of the workflow input must match the Workflow Role of a reference data element, in order for that element to be used.

To configure a secondary input, double-click the name of the input. You can now select an element under Workflow Input, which will configure the input for situation 1) (as seen in figure 10.4). Or you can enter a Workflow Role to configure the input for situation 2) (figure 10.5). You can either type in a role name of your choice, or choose one from the drop down list, as long as there will be a reference data set with a matching role.
Figure 10.4: Selecting a particular element to configure the workflow with. Remember to lock the configuration before saving the workflow if you want this step not to appear in the workflow’s wizard.

Figure 10.5: Selecting a particular role to configure the workflow with. Remember to lock the configuration before saving the workflow. The workflow’s wizard will include a step where you can choose a reference data set.

Note: When running the workflow, the workflow wizard makes it possible to override the configuration of any unlocked Workflow Input. If you want to make sure that the workflow always runs according to your configuration, then lock the configuration by clicking the Lock icon. Learn more about locking parameters in section 10.1.4.

10.1.3 Configuring workflow tools

Each of the tools can be configured by right-clicking the name of the tool as shown in figure 10.6.

The first option you are presented with is the option to Rename the element. This can be useful when you wish to discriminate between several copies of the same tool in a workflow. The name of the element is also visible as part of the process description when the workflow is run. To rename the element, right click on the tool in the workflow and select the "Rename" option, or click on the tool in the workflow and then press the F2 key.

The Remove option is used to remove elements from the workflow. The shortcut Alt + Shift + R
removes all elements from the workflow.

You can also configure a given element using the **Configure** option from the right click menu or by double-clicking on the element. This opens a dialog with options for setting parameters, selecting reference data, selecting the export destination of specified columns, etc. An example is shown in figure 10.7.

Click through the dialogs using **Next** and press **Finish** when you are done. This saves the parameter settings for that tool. These are then applied when the workflow is executed.

You can also change the name of a parameter if you so wish, for example, to help with usability for the intended users of a workflow. To do this, click on the edit icon (-pencil) and enter a new name.

The lock icons in the dialog are used for specifying whether the parameter should be locked and unlocked as described in the next section. Locking parameters means that the workflow will be run with the same parameters every time; the user will not be prompted to supply values for locked parameters when they launch the workflow.
Once an element has been configured, the workflow element will be shaded with a darker color to help in distinguishing which elements have been configured.

The **Highlight Subsequent Path** option causes the element that was clicked on, and all the elements downstream of that one, to be highlighted. Other elements will be grayed out (figure 10.8). The **Remove Highlighting Subsequent Path** option reverts the highlighting, returning to the normal workflow layout.

Similarly, instead of configuring the various tools individually, the **Configuration Editor** enables the specification of all settings, references, masking parameters etc. through a single wizard window (figure 10.9). This editor is accessed through the (icon) located in the lower left corner.
10.1.4 Locking and unlocking parameters

When creating the workflow, the workflow author can specify which parameters should be locked or unlocked. If a parameter is locked, it cannot be changed in the installation or the execution step. Conversely, if it is left open, that parameter can be changed, either when running the Workflow or when installing it (see section 10.2).

By default, data parameters are unlocked. When installing the workflow on a different system to the one where it was created, the connection to the data needs to be re-established. This is only possible when the parameter is unlocked. Data parameters should only be locked if they should not be set, or if the workflow will only be installed in a setting where there is access to the same data in the same location as the system where the Workflow was created.

10.1.5 Connecting workflow elements

Figure 10.10 explains the different parts of a workflow element.

Figure 10.10: A workflow element consists of three parts: input, name of the tool, and output. The primary inputs are colored with a light grey background, and the secondary inputs (parameter inputs) are colored with a brown background.

At the top of each element a description of the required type of input is found. In the right-hand side, a symbol specifies whether the element accepts multiple incoming connections, e.g. +1 means that more than one output can be connected, and no symbol means that only one can
be connected. At the bottom of each element there are a number of small boxes that represent the different kinds of output that is produced. In the example with the read mapper shown in figure 10.2, the read mapper is able to produce a reads track, a report etc.

Each of the output boxes can be connected to further analysis in three ways:

- **By dragging with the mouse from the output into the input box of the next element.** This is shown in figure 10.11. A green border around the box will tell you when the mouse button can be released, and an arrow will connect the two elements (see figure 10.12).

- **Right-clicking the output box will display a list of the possible elements that this output could be connected to.** You can also right-click the input box of an element and connect this to a matching output of another element.

- **Alternatively, if the element to connect to is not already added, you can right-click the output and choose Add Element to be Connected.** This will bring up the dialog from figure 10.1, but only showing the tools that accepts this particular output. Selecting a tool will both add it to the workflow and connect with the output you selected. You can also add an upstream element of workflow in the same way by right-clicking the input box.

```

<td>Read Mapping</td>
<td>Mapping Report</td>
</tr>
</tbody>
</table>
```

(Click for full image)

**Figure 10.12:** The reads track is now used for variant calling.

All the logic of combining output and input is based on matching the type of input. So the read mapper creates a reads track and a report as output. The variant detection tool accepts reads tracks as input but not mapping reports. This means that you will not be able to connect the mapping report to the variant detection tool.

Figure 10.13 demonstrates how one tool can receive input from two different sources; 1) a reads track that is the input that hold the data that is to be analyzed (in this case reads that is to be locally realigned), and 2) a parameter that can have different functions depending on the tool that it is connected to (in this case the InDel track is used as a guidance track for the local realignment. In other situations the parameter track could be used for e.g. annotation or could provide a reference sequence).
Figure 10.13: A tool can receive input from both the generated output from another tool (in this example a reads track) and from a parameter (in this case indels detected with the InDels and Structural Variants tool).

10.1.6 Output

Besides connecting the elements together, you have to decide what the input and the output of the workflow should be. We will first look at specification of the output, which is done by right-clicking the output box of any tool and selecting Use as Workflow Output as shown in figure 10.14.

Figure 10.14: Selecting a workflow output.

You can mark several outputs this way throughout the workflow. Note that no intermediate results are saved unless they are marked as workflow output. In fact, when the workflow is executed, all the intermediate results are indeed saved temporarily, but they are automatically deleted when the workflow is completed. However, if a workflow fails, the intermediate results are not deleted and will be found in a folder named after the workflow with the mention “intermediate”.

By double-clicking the output box, you can specify how the result should be named as shown in
In this dialog you can enter a name for the output. Dynamic placeholders are available, which can help in setting up specific and standardized names for outputs. If you mouse over the Custom output name field in the dialog, the placeholders are listed. You can also click on Shift+F1 to see the options. The placeholders below are available. They are not case specific.

- `{name}` or `{1}` - default name for the tool’s output
- `{input}` or `{2}` - the name of the workflow input (and not the input to a particular tool within a workflow).
- `{user}` - name of the user who launched the job
- `{host}` - name of the machine the job is run on
- `{year}`, `{month}`, `{day}`, `{hour}`, `{minute}`, and `{second}` - timestamp information based on the time an output is created. Using these placeholders, items generated by a workflow at different times can have different filenames.

When deciding on an output name, you can choose any combination of the placeholders, as well as custom names and punctuation, for example, `{input}({day}-{month}-{year})`. A meaningful name to a variant track could be `{2} variant track` as shown in figure 10.16. Here, if your workflow input was named `Sample 1`, the result would be "Sample 1 variant track".

The placeholders available for exports are slightly different than for other workflow outputs and are described in section 6.6.

It is also possible to save workflow outputs into subfolders by using a forward slash character `/` at the start of the output name definition. For example the custom output name
/variants/{name} refers to a folder "variants" that would lie under the location selected for storing the workflow outputs. When defining subfolders for outputs, all later forward slash characters in the configuration, except the last one, will be interpreted as further levels of subfolders. For example, a name like /variants/level2/level3/myoutput would put the data item called myoutput into a folder called level3 within a folder called level2, which itself is inside a folder called variants. The variants folder would be placed under the location selected for storing the workflow outputs. If the folders specified in the configuration do not already exist, they are created.

Exports are different to other workflow outputs in this regard; subfolders cannot be defined using the Custom file name field. If slash characters are included in the Custom file name field for an export, all text before and including the final slash character is ignored.

### 10.1.7 Input

In addition to output, you also have to specify where the data should go into the workflow by adding an element called Workflow Input. This can be done by:

- Right-clicking the input box of the first tool and choosing Connect to Workflow Input. By dragging from the workflow input box to other input boxes several tools can use the input data directly.

- Pressing the button labeled Add Element (or right-click somewhere in the workflow background area and select Add Element from the menu that appears). The input box must then be connected to the relevant tool(s) in the workflow by dragging from the Workflow Input box to the "input description" part of the relevant tool(s) in the workflow.

At this point you have only prepared the workflow for receiving input data, but not specified which data to use as input.

Multiple input files can be used when:

- Data is generated within the Workflow
- Data is held within the Workbench
- Data is a combination of the two situations above

It can be useful to rename input elements when working with multiple input files, so that it is easy to discriminate between them when they are shown during workflow execution.

**Note:** Once the multiple input feature is used in a workflow, it is not possible to run the workflow in batch mode.

You can choose the order in which inputs will be processed by an element by right clicking on the input parameter box at the top of the element and choosing the option Order Inputs. This is most relevant for elements involved in data visualization. The feature Order Inputs is enabled when there are at least two inputs connected to the element (see figure 10.17). A small window will open, in which you can indicate the preferred order of the inputs to that element by moving them up and down in the list (figure 10.18). From this point forward, the order of the inputs is displayed on the branches connecting the inputs to elements.
The feature **Order Workflow Inputs** allows you to set the order that a user will be asked for each input when they run the workflow. This option is enabled as soon as the workflow has two or more inputs (figure 10.19). Right click on empty space in the Workflow editor to start this tool. A small window will open in which the different inputs can be moved up and down to indicate the desired order (figure 10.20).

The example in figure 10.21 shows how to generate a track list in a workflow. Any track based on a compatible genome can be added to the same track list. This includes reference tracks as well as track results generated by elements of that workflow. In the latter case, only those for
Figure 10.19: Right click on empty space in the Workflow editor to open the Order Workflow Inputs tool.

Figure 10.20: Define the order of the inputs for the workflow.

which a workflow output element has been configured can be included in a track list.

10.1.8 Layout

The workflow layout can be adjusted automatically. Right clicking in the workflow editor will bring up a pop-up menu with the option "Layout". Click on "Layout" to adjust the layout of the selected elements (Figure 10.22). Only elements that have been connected will be adjusted.

Note! The layout can also be adjusted with the quick command Shift + Alt + L.

Note! It is very easy to make an image of the workflow. Simply select the elements in the workflow (this can be done pressing Ctrl + A, by dragging the mouse around the workflow while
Figure 10.21: Generation of a track list including data generated within the Workflow, as well as data held in the Workbench.

Figure 10.22: A workflow layout can be adjusted automatically with the "Layout" function.

holding down the left mouse button, or by right clicking in the editor and then selecting "Select All"), then press the Copy button in the toolbar (COPY) or CTRL + C. Press Ctrl + V to paste the image into the wanted destination e.g. an email or a text or presentation program.
10.1.9 Input modifying tools

An input modifying tool is a tool that manipulates its input objects (e.g. adds annotations) without producing a new object. This behavior differs from the rest of the tools and requires special handling in the workflow.

In the workflow an input modifying tool is marked with the symbol (M) (figure 10.23).

![Figure 10.23: Input modifying tools are marked with the letter M.](image)

Restrictions apply to workflows that contain input modifying tools. For example, branches are not allowed where one of the elements is a modifying tool (see figure 10.24), as it cannot be guaranteed which workflow branch will be executed first, which in turn means that different runs can result in production of different objects. Hence, if a workflow is constructed with a branch where one of the succeeding elements is a modifying tool, a message in red letters will appear saying "Branching before a modifying tool can lead to non-deterministic behavior". In such a situation the "Run" and "Create Installer" buttons will be disabled (figure 10.24).

![Figure 10.24: A branch containing an input modifying tool is not allowed in a workflow.](image)

The problem can be solved by resolving the branch by putting the elements in the right order (with respect to order of execution). This is shown in figure 10.25 that also shows that the "Run" and "Create Installer" buttons are now enabled. In addition, a message in green letters has appeared saying "Validation successful".

As input modifying tools only modify existing objects without producing a new object, it is not possible to add a workflow output element directly after an input modifying tool (figure 10.26). A workflow output element can only be added when other tools than input modifying tools are included in the workflow.
Figure 10.25: A branch containing an input modifying tool has been resolved and the workflow can now be run or installed.

Figure 10.26: A workflow output element cannot be added if the workflow only contains an input modifying tool.

If the situation occurs where more input modifying tools are used successively, a copy of the object will be created in addition to using the modified object as input at the next step of the chain (see figure 10.27). In order to see this output you must right click on the output option (marked with a red arrow in figure 10.27) and select "Use as Workflow Output".

When running a workflow where a workflow output has been added after the first input modifying tool in the chain (see figure 10.28) the output arrow is marked with "copy" to indicate that this is a copy of the result that is used as input at the next level in the chain. When running this workflow you will be able to see the copy of the output from the first input modifying tool in the Navigation Area (at the destination that you selected when running the workflow).

10.1.10 Workflow validation

At the bottom of the view, there is a text with a status of the workflow (see figure 10.29). It will inform about the actions you need to take to finalize the workflow.
Figure 10.27: A workflow output element can be added when more than one input modifying tool is used successively (despite that the workflow only contains input modifying tools). Select "Use as Workflow Output" to make a copy of the output.

Figure 10.28: A workflow output element can be added when more than one input modifying tool is used successively (despite that the workflow only contains input modifying tools). Note that this output is marked with "copy" to indicate that this is a copy of the result that is used as input at the next level in the chain.

Figure 10.29: A workflow is constantly validated at the bottom of the view.

The validation may contain several lines of text. Scroll the list to see more lines. If one of the errors pertain to a specific element in the workflow, clicking the error will highlight this element.

The following needs to be in place before a workflow can be executed:

- All input boxes need to be connected either to the workflow input or to the output of other tools.
- At least one output box from each tool needs to be connected to either a workflow output or to the input box of another tool.
- Additional checks that the workflow is consistent.

Once these conditions are fulfilled, the status will be "Validation successful". Clicking the Run button will enable you to try running a data set through the workflow to test that it produces the
expected results. If reference data has not been configured (see section 10.1.3), there will be a
dialog asking for this as part of the test run.

10.1.11 Workflow creation helper tools

In the workflow editor Side Panel, you will find the following workflow display settings that can be
useful to know (figure 10.30):

Grid

- Enable grid You can display a grid and control the spacing and color of the grid. Per
default, the grid is shown, and the workflow elements snap to the grid when they are
moved around.

View mode

- Collapsed The elements of the workflow can be collapsed to allow a cleaner view and
especially for large workflows this can be useful.
- Highlight used elements Ticking Highlight used elements (or using the shortcut Alt
+ Shift + U) will show all elements that are used in the workflow whereas unused
elements are grayed out.
- Rulers Vertical and horizontal rules can be visualised
- Auto Layout Ticking Auto Layout will ensure rearrangement of elements once new
elements are added.
- Connections to background Connecting arrows are shown behind elements. This may
easy reading of element names and accessible parameters.

Design

- Round elements Enable rounding of the element boxes.
- Show shadow Shadows of element boxes can be added.
- Configured elements Background color can be customized.
- Input elements Background color can be customized.
- Edges Color of connecting arrows can be customized.

10.1.12 Adding to workflows

Additional elements can be added to an already existing workflow by dragging it from the
navigation area into the workflow editor and joining more elements as necessary. The new
workflow must be saved and validated before it can be executed. Two or more workflows can be
joined by dragging and dropping one from the Navigation Area, into another that is already open
in the main viewing area. The output of one must be connected to the input of the next to allow
the whole workflow to run in one go.

Workflows do not need to be valid to be dragged in to the workflow editor, but they must have
been updated to the current version of the workbench.
10.1.13 Snippets in workflows

When creating a new workflow, you will often have a number of connected elements that are shared between workflows. Instead of building workflows from scratch it is possible to reuse components of an existing workflow. These components are called snippets and can exist of e.g. a read mapper and a variant detection tool.

Snippets can be created from an existing workflow by selecting the elements and the arrows connecting the selected elements. Next, you must right-click in the center of one of the selected elements. This will bring up the menu shown in figure 10.31.

When you have clicked on "Install as snippet" the dialog shown in figure 10.32 will appear. The dialog allows you to name the snippet and view the selected elements that are included in the snippet. You are also asked to specify whether or not you want to include the configuration of the selected elements and save it in the snippet or to only save the elements in their default configuration.

Click on the button labeled OK. This will install your snippet and the installed snippet will now appear in the Side Panel under the "Snippets" tab (see figure 10.33).

Right-clicking on the installed snippet in the Side Panel will bring up the following options (figure 10.34):

- **Add** Adds the snippet to the current open workflow
- **View** Opens a dialog showing the snippet, which allows you to see the structure
- **Rename** Allows renaming of the snippet.
- **Configure** Allows to change the configuration of the installed snippet.
Figure 10.31: The selected elements are highlighted with a red box in this figure. Select "Install as snippet".

- **Uninstall** Removes the snippet.
- **Export** Exports the snippet to one's computer, allowing to share it.
- **Update** Updates the snippet (if update is required).

If you right-click on the top-level folder you get the options shown in figure 10.35:

- **Create new group** Creates a new folder under the selected folder.
- **Remove group** Removes the selected group (not available for the top-level folder)
- **Rename group** Renames the selected group (not available for the top-level folder)

In the Side Panel it is possible to drag and drop a snippet between groups to be able to rearrange and order the snippets as desired. An exported snippet can either be installed by clicking on the "Install from file" button or by dragging and dropping the exported file directly into the folder where it should be installed.
Figure 10.32: In the "Create a new snippet" dialog you can name the snippet and select whether or not you would like to include the configuration. In the right-hand side of the dialog you can see the elements that are included in the snippet.

Add a snippet to a workflow  Snippets can be added to a workflow in two different ways; it can either be added by dragging and dropping the snippet from the Side Panel into the workflow editor, or it can be added by using the "Add elements" option that is shown in figure 10.36.

10.1.14 Change the order of tracks in the Track List

When modifying an existing workflow or creating a custom workflow that include the tool Create Track List you may want to be able to adjust the order in which the tracks are shown in the Track List. To do this, display a view of the workflow layout, click once on the top part of the tool Create Track List labeled "Tracks" followed by a right-click. In the pop up menu that appears (figure 10.37), choose the option "Order Workflow Inputs". This opens a new pop up window (figure 10.38 where you can see a list of all the inputs that are connected with the input channel of the Create Track List tool. Use the arrows found in the left-hand side to move the tracks up or down until you have the desired track order in your Track List.

If the workflow also generated several variant tracks, the variant table generated from the uppermost read mapping will open in split view with the Track List. By changing the Order of Inputs you can thus also influence which variant table should open in split view.
10.2 Distributing and installing workflows

Once the workflow has been configured, you can use the Run button (see section 10.1.10) to process data through the workflow, but the real power of the workflow is its ability to be distributed and installed in the Toolbox alongside the other tools that come with the CLC Genomics Workbench, as well as the ability to install the same workflow on a CLC Genomics Server. The mechanism for distributing the workflow is a workflow installer file which can be created from the workflow editor and distributed and installed in any Workbench or Server.
10.2.1 Creating a workflow installation file

At the bottom of the workflow editor, click the **Create Installer** button (or use the shortcut Shift + Alt + I) to bring up a dialog where you provide information about the workflow to be distributed (see an example in figure 10.39).

The information entered in this dialog will be visible for users installing the workflow and will enable them to look up the source of the workflow any time.

**Author name** Provide the name of the author of the workflow.

**Author email** Provide the email of the author of the workflow.

**Author homepage** Provide the homepage of the author of the workflow.
CHAPTER 10. WORKFLOWS

Figure 10.38: Example of Order Inputs window that appears when choosing the option "Order Inputs...".

Figure 10.39: Workflow information for the installer.

**Organization** The organization name is important because it is part of the workflow id (see more in section 10.2.4).

**Workflow name** The workflow name is based on the name used when saving the workflow in the Navigation Area. The workflow name is essential because it is used as part of the workflow id (see more in section 10.2.4). The workflow name can be changed during the installation of the workflow. This is useful whenever you have a workflow that you would like to use e.g. with small variations. The original workflow name will remain the same in the Navigation Area - only the installed workflow will receive the customized name.

**ID** The final id of the workflow.

**Workflow icon** An icon can be provided. This will show up in the installation overview and in the Toolbox once the workflow is installed. The icon should be a 16 x 16 pixels gif or png file. If the icon is larger, it will automatically be resized to fit 16 x 16 pixels.
Workflow version  A major and minor version can be provided.

Workflow description  Provide a textual description of the workflow. This information will be displayed when a user mouses-over the name of the installed Workflow in the Workbench Toolbox, and is also presented in the Description tab for that Workflow in the Manage Workflows tool, described in section 10.2.3. Simple HTML tags are allowed (should be HTML 3.1 compatible, see http://www.w3.org/TR/REC-html32).

If you configured any of the workflow elements with data, clicking Next will give you the following options for the reference data (see figure 10.40). You can choose to

- Ignore. This is the recommended setting when the workflow inputs have been configured with workflow roles. The user installing the workflow on their local system will have to apply their own references.

- Reference. This is the recommended setting when the workflow inputs have been configured by selecting elements in a shared CLC_References directory. The data will not be bundled with the workflow, but the reference data is included in the workflow by pointing to the shared data in the CLC_References directory. This is particularly useful when working with large reference data.

- Bundle. This is the recommended setting when you cannot, or do not wish, to share the data through a CLC_References folder (see section 8.4 for how to transfer data to a CLC_References folder.) This option will include the data in the workflow by directly bundling the reference data with the workflow. Note! Bundling data should only be used to bundle small data sets with the workflow installer.

Click Next and you will be asked to specify where to install the workflow (figure 10.41). You can install your workflow directly on your local computer. If you are logged on a server and are the administrator, the option "Install the workflow on the current server" will be enabled. Finally, you can select to save the workflow as a .cpw file that can be installed on another computer. Click Finish. This will install the workflow directly on the selected destination. If you have selected to save the workflow for installation on another computer, you will be asked where to save the file after clicking Finish. If you chose to bundle data with your workflow installation, you will be asked for a location to put the bundled data on the workbench. Installing a workflow with bundled data on a server, the data will be put in a folder created in the first writable persistence location. Should this location not suit your needs, you can always move it afterwards, using the normal persistence operations.
In cases where an existing workflow that has already been installed is modified, the workflow must be reinstalled. This can be done by first saving the workflow after it has been modified and then pressing the Create Installer button. Click through the wizard and select whether you wish to install the modified workflow on your local computer or on a server. Press Finish. This will open a pop-up dialog "Workflow is already installed" (figure 10.42) with the option that you can force the installation. This will uninstall the existing workflow and install the modified version of the workflow. Note! When forcing installation of the modified workflow, the configuration of the original workflow will be lost.

10.2.2 Installing a workflow

Workflow .cpw files can be installed on a Workbench using the workflow manager:

Help | Manage Workflows ( )

or press the "Workflows" button ( ) in the toolbar and then select "Manage Workflow..." ( ).

To install a workflow, click on Install from File and select a .cpw file. If the workflow has bundled data, you will be prompted for a location for that data. Once installed, the workflow will appear under the Installed Workflows tab (figure 10.43).

Information on how to create a .cpw file can be found section 10.2.1.
10.2.3 Managing workflows

Workflows can be managed from the workflow manager:

- Help | Manage Workflows (\(\mathbb{F}\))

or using the "Workflows" button (\(\mathbb{F}\)) in the toolbar and then select "Manage Workflow..." (\(\mathbb{F}\)).

The workflow manager lists Installed workflows and Ready-to-Use workflows, but the functionalities described below (Configure, Rename, and Uninstall) are only available to custom workflows. You can always create a copy of a Ready-to-Use workflow (by opening the Ready-to-Use workflow and saving a copy in your Navigation Area) to enable the options described below.

Configure  Select the workflow of interest and click on the button labeled Configure. You will be presented with a dialog listing all the reference data that need to be selected. An example is shown in figure 10.44.

This dialog also allows you to lock parameters of the workflow (see more about locking in section 10.1.4).

Note that if the workflow is intended to be executed on a server, it is important to select reference
data that is located on the server.

**Rename** In addition to the configuration option, it is also possible to rename the workflow. This will change the name of the workflow in the Toolbox. The workflow id (see below) remains the same. To rename an element right click on the element name in the Navigation Area and select "Rename" or click on the F2 button.

**Uninstall** Use this button to install a workflow.

**Description, Preview and Information** In the right side of the window, you will find three tabs. **Description** contains the description that was entered when creating the workflow installer (see figure 10.39), the **Preview** shows a graphical representation of the workflow (figure 10.45), and finally you can get **Information** about the workflow (figure 10.46).

![Figure 10.45: Preview of the workflow.](image)

The "Information" field (figure 10.46) contains the following:

![Figure 10.46: Workflow identification and versioning.](image)
**Build id** The date (day month year) followed by the time (based on a 24 hour time) when the workflow was exported to a file through the Installation button at the bottom of the workflow window. If the workflow was installed locally without going through a file, the build ID will reflect the time of installation.

**Download href** The name of the workflow .cpw file

**Id** The unique id of a workflow, by which the workflow is identified

**Major version** The major version of the workflow

**Minor version** The minor version of the workflow

**Name** Name of workflow

**Rev version** Revision version. The functionality is activated but currently not in use

**Vendor id** ID of vendor that has created the workflow

**Version** `<Major version>.<Minor version>`

**Workbench api version** Workbench version

**Workflow api version** Workflow version (a technical number that can be used for troubleshooting)

### 10.2.4 Workflow version and update

A workflow has a version. The version is used to make it easy to distribute an improved version of the same workflow. To do this, create a new installer with an incremented version number. In order to install a new and updated version, the old one has to be uninstalled.

If a workflow needs to be updated, it must be updated before it can be used. Please note that:

- When you update a workflow, the older version is overwritten.
- If new parameters have been added to a tool as part of the update, these parameters will be set to their default values within the updated workflow.

**Updating workflows in the Navigation area** If a workflow stored in a CLC Data Location needs to be updated, this will become apparent when it is opened from the Navigation Area of the Workbench. In this case, an editor appears that lists the tools that need to be updated (figure 10.47). The workflow must be updated before it will be opened in the Workflow editor, and edited or launched. Click on the **OK** button at the bottom of the editor to update the workflow.

**Updating installed workflows within the same major release line**

"Major release line" refers to the first digit in the version number. For example: CLC Genomics Workbench 10.0.1 and 10.5 are releases within the same major release line. The major release number here is 10. CLC Genomics Workbench 9.x is is part of a different major release line than 10.x because the major version number is different (9 versus 10).
You can update installed workflows within the same major release line using the Workflow Manager tool.

Open the "Manage Workflows..." tool by selecting it after clicking on the "Workflows" button in the top toolbar of the Workbench (see figure 10.48) Select the workflow that needs to be updated. Workflows you installed directly will be under the "Custom Workflows" tab. Click on the "Update" button.

To update a workflow you must have permission to write to the area the workflow is stored in. For workflows you installed directly, you will normally be able to do this when running the Workbench as you usually do. To update workflows distributed via plugins, it will usually mean running the Workbench as an administrative user.

**Updating installed workflows between major release lines** To update a workflow between major release lines, a Workbench version the installed workflow can be run on is needed, as well as the latest version of the Workbench.

To start, open a copy of the installed workflow in a version of the Workbench it can currently be run on. This is done by selecting the workflow in the Installed Workflows folder of the Toolbox.
in the bottom left side of the Workbench, then right-clicking on the workflow name and choosing the option “Open Copy of Workflow” (figure 10.49).

Figure 10.49: Open a copy of an installed workflow by right-clicking on its name in the Workbench Toolbox.

Save the copy of the workflow in the Navigation Area. To do this, you can simply drag and drop the tab to the location of your choice in the Navigation Area.

Open the new version of the Workbench and there, open the workflow that was saved in the Navigation Area. Click on the OK button if you are prompted to update the workflow.

You can now check that the workflow has been updated correctly, including that any reference data is configured as expected. Then save the updated version of the workflow. Finally, click the Installation button to install the workflow, if desired.

If the above process does not work when upgrading directly from a much older Workbench version, it may be necessary to upgrade step-wise by upgrading the workflow in sequentially higher major versions of the Workbench.

10.3 Executing a workflow

Once installed and configured, a workflow will appear in the Toolbox under Installed Workflows ( ). If an icon was provided with the workflow installer this will also be shown (see figure 10.50).

Figure 10.50: A workflow is installed and ready to be used.
The workflow is executed just as any other tool in the Toolbox by double-clicking or selecting it in the menu (or with the shortcut Ctrl + Enter). This will open a dialog where you select (and potentially download) relevant reference data, provide input data and configure the tools whose parameters have been left unlocked. Most workflows can also be run in batch mode (see section 9.3). In the last page of the dialog, you can preview all the parameters of the workflow, as well as the input data, before clicking "Next" to choose where to save the output, and then "Finish" to execute the workflow.

If you are connected to a CLC Genomics Server, you will be presented with the option to run the workflow locally on the Workbench or on the Server. When you are selecting where to run the workflow, you should also see a message should there be any missing configurations. There are more details about running Workflows here: http://resources.qiagenbioinformatics.com/manuals/clcgenomicsworkbench/current/index.php?manual=Workflows.html.

When the workflow is started, you can see the log file with detailed information from each step in the process.

If the workflow is not properly configured, you will see that in the dialog when the workflow is started.

10.4 Open copy of installed workflow

A copy of an installed and configured workflow found in the Toolbox under Workflows can be opened in the View Area by clicking once and then right-clicking on the name of the installed workflow in the toolbox (figure 10.51).

Figure 10.51: A copy of an installed workflow can be opened from the Toolbox. The copied workflow will open in the View Area.

An example of a copy of a workflow that has been opened in the View Area is shown in figure 10.52.

10.5 Batch launching workflows with multiple inputs

This section describes the launching of workflows with multiple inputs, where all input elements will be changed per batch. This launch mechanism is not intended for workflows with multiple input elements where one of the input elements remains the same in all batches, such as workflows meant to compare several tissues to a unique control tissue. At the moment, batch launching of such workflows is not possible, unless the common item is saved under different names as many times as there should be batches.

For workflows with multiple inputs where the inputs all need to change for each batch run, information specifying the grouping of the data elements and what role each element plays in a

---

1 If the workflow uses a tool that is part of a plugin, a missing plugin can also be the reason why the workflow is not enabled. A workflow can also become outdated because the underlying tools have changed since the workflow was created (see section 10.2.4)
given analysis needs to be imported into the system from an Excel spreadsheet.

The requirements for launching such workflows in batch mode are:

- **The workflow must be installed on the Workbench**, meaning that the workflow is accessible from the Toolbox (as opposed to workflows accessible from the Navigation Area). See section 10.2 to learn how to install a workflow.

- **The workflow is characterized by more than one input file**, and all input elements are unique per batch. You cannot reuse a common input element (such as control reads for example), unless it has been saved under different names in the Navigation Area.

- **An Excel format file (.xlsx/.xls) must be provided**, with at least 3 different columns:
  
  - **Unique ID** The first column must contain either the exact name of the data elements to be used as inputs, or partial name information such that data elements being entered into the analysis can be uniquely identified and matched with the information contained in the spreadsheet (see section 3.2.3 to learn more about matching partial names).

  - **Grouping** A second column must specify which data elements should be analyzed together in a given batch unit: this would be the ID of a single individual when comparing different tissues from the same individual (one individual per batch); or a family name when identifying variants existing within one family (one family per batch).

  - **Type** The third column must specify the type for each data element: the values in this column distinguish tissue samples from controls, or inform about the disease status
of a family member (affected/non-affected/proband) when identifying disease causing variants.

(Figure 10.53) shows an example of a spreadsheet used in the case of tissue comparison. Note that the "grouping" and "type" are context specific, and will depend on the analysis performed, i.e., on the tools that constitute the workflow.

</tbody>
</table>

Figure 10.53: Example of a spreadsheet necessary to run a workflow in batch, where the workflow intend to compare two tissue samples.

To launch a workflow with multiple input elements in batch mode, right click on the name of the workflow in the Toolbox and select the option "Run in Batch Mode..." (figure 10.54).

A wizard opens and in the first window, you need to specify:

- An Excel file containing the information about the data to be analyzed (figure 10.55). Note that this file does not need to be saved in your Navigation Area. When it has been selected, the table found in the lower part of the wizard will show recapitulate the content of the Excel sheet. The location of the data for this analysis is not yet specified, so a red, no-entry sign is visible in the header of the first column.

- The location of the reads: click on the Navigation button next to the "Location of data" field and specify the folder(s) that contain(s) the data, as shown in figure 10.56.

Data elements within the selected folders are considered for the analysis. Subfolders and their contents are not considered unless the subfolder is also selected. Individual data elements cannot be selected.
CHAPTER 10. WORKFLOWS

Figure 10.55: Select the information about the data to be analyzed and the folder holding the data to analyze. An example of an Excel sheet with the relevant information is shown.

Figure 10.56: Select the folder(s) that contain(s) the data to be analyzed.

- Select the appropriate matching scheme - exact or partial. The matching rules applied are the same as those used for metadata association: "Exact" means that data element names must exactly match an entry in the first column of the Excel file; "Partial" matching allows for data elements names partially matching an entry in the first column. "Exact" is selected by default. Partial matching rules are described in detail in section 3.2.3.

An icon with a green check mark (✓) appears in the table preview next to rows where a data element corresponding to a row of the Excel sheet was uniquely identified. If no match can be made to a given row of the Excel sheet, a question mark (?) is displayed.

Graphical symbols are also presented in the header of the first column of the preview pane to give information about the overall status of the matching of rows in the Excel sheet with data elements in the Workbench:

- When no data elements match information in the Excel sheet, a red, no entry symbol (🚫)
is displayed. In this situation, the button labeled Next is not enabled. This is the expected state before any data elements have been selected.

- A yellow exclamation mark (!) indicates that some, but not all rows in the Excel sheet have been matched to a data element in the selected folder(s).

- A green checkmark (✓) indicates that all rows in the Excel sheet have been matched to a data element in the selected folder(s).

In figure 10.57, the green check mark symbol in the header of the first column in the preview pane indicates that data elements were identified for each of the rows in the Excel sheet. You can click on the button labeled "Next".

![Image](image.png)

Figure 10.57: View of the Data Association table after all samples were successfully associated.

The next wizard window is called "Select grouping parameters and analysis inputs".

- In the Group by drop down menu, select the name of the column containing information that specifies which samples should be analyzed together.

- In the Type drop down menu, select the name of the column containing information that can be mapped to the workflow input type of each data element.

In the same window you will need to further specify the inputs of the workflow. What needs to be specified here is dependant on the workflow itself.

An example is shown in figure 10.58. Group by is set to a column specifying "Patient ID", because each workflow run will analyze a sample pair. Type is set to the "Type" column, because the workflow inputs are either tumor or normal tissues. The sample columns section maps data elements to the different workflow inputs, in this case "Tissue sample" is set to "Tumor", and "Control tissue sample" to "Normal".

The rest of the wizard is dependant of the tools included in the workflow. Fill in the appropriate information and save the results of your workflow in a folder you can create in the Navigation Area.
As in a regular batching mode, you can use the progress bar to see how the job is progressing (figure 10.59); a process called "Batch Process" indicates how many batches have been completed, while the ones situated above show the analysis progress of a particular batch unit.

Figure 10.58: Grouping samples.

Figure 10.59: Check on the progress of your workflow being run in batch mode using the Processes tab below the Toolbox.

11.6 Sequence Lists ...................................................... 263

CLC Genomics Workbench offers five different ways of viewing and editing single sequences as described in the first five sections of this chapter. Furthermore, this chapter also explains how to create a new sequence and how to gather several sequences in a sequence list.

11.1 View sequence

When you double-click a sequence in the Navigation Area, the sequence will open automatically, and you will see the nucleotides or amino acids. The zoom options described in section 2.2 allow you to e.g. zoom out in order to see more of the sequence in one view. There are a number of options for viewing and editing the sequence which are all described in this section.

All the options described in this section also apply to alignments (further described in section 20.2).
11.1.1 Sequence settings in Side Panel

Each view of a sequence has a Side Panel located at the right side of the view (see figure 11.1.

Figure 11.1: Overview of the Side Panel which is always shown to the right of a view.

When you make changes in the Side Panel the view of the sequence is instantly updated. To show or hide the Side Panel:

- select the View | Ctrl + U
- or Click the (↑) at the top right corner of the Side Panel to hide | Click the (↓) to the right to show

Below, each group of settings will be explained. Some of the preferences are not the same for nucleotide and protein sequences, but the differences will be explained for each group of settings.

Note! When you make changes to the settings in the Side Panel, they are not automatically saved when you save the sequence. Click Save/restore Settings (保存) to save the settings (see section 4.6 for more information).

Sequence Layout

These preferences determine the overall layout of the sequence:

- **Spacing.** Inserts a space at a specified interval:
  - No spacing. The sequence is shown with no spaces.
  - Every 10 residues. There is a space every 10 residues, starting from the beginning of the sequence.
  - Every 3 residues, frame 1. There is a space every 3 residues, corresponding to the reading frame starting at the first residue.
  - Every 3 residues, frame 2. There is a space every 3 residues, corresponding to the reading frame starting at the second residue.
  - Every 3 residues, frame 3. There is a space every 3 residues, corresponding to the reading frame starting at the third residue.

- **Wrap sequences.** Shows the sequence on more than one line:
  - No wrap. The sequence is displayed on one line.
  - Auto wrap. Wraps the sequence to fit the width of the view, not matter if it is zoomed in or out (displays minimum 10 nucleotides on each line).
- **Fixed wrap.** Makes it possible to specify when the sequence should be wrapped. In the text field below, you can choose the number of residues to display on each line.

- **Double stranded.** Shows both strands of a sequence (only applies to DNA sequences).

- **Numbers on sequences.** Shows residue positions along the sequence. The starting point can be changed by setting the number in the field below. If you set it to e.g. 101, the first residue will have the position of -100. This can also be done by right-clicking an annotation and choosing **Set Numbers Relative to This Annotation**.

- **Numbers on plus strand.** Whether to set the numbers relative to the positive or the negative strand in a nucleotide sequence (only applies to DNA sequences).

- **Lock numbers.** When you scroll vertically, the position numbers remain visible. (Only possible when the sequence is not wrapped.)

- **Lock labels.** When you scroll horizontally, the label of the sequence remains visible.

- **Sequence label.** Defines the label to the left of the sequence.
  - Name (this is the default information to be shown).
  - Accession (sequences downloaded from databases like GenBank have an accession number).
  - Latin name.
  - Latin name (accession).
  - Common name.
  - Common name (accession).

- **Matching residues as dots** Residues in aligned sequences identical to residues in the first (reference) sequence will be presented as dots. An option that is only available for "Alignments" and "Read mappings".

**Annotation Layout and Annotation Types** See section 11.3.1.

**Restriction sites**
See section 11.1.1.

**Motifs**
See section 14.9.1.

**Residue coloring**
These preferences make it possible to color both the residue letter and set a background color for the residue.

- **Non-standard residues.** For nucleotide sequences this will color the residues that are not C, G, A, T or U. For amino acids only B, Z, and X are colored as non-standard residues.
– **Foreground color.** Sets the color of the letter. Click the color box to change the color.
– **Background color.** Sets the background color of the residues. Click the color box to change the color.

- **Rasmol colors.** Colors the residues according to the Rasmol color scheme.
  – **Foreground color.** Sets the color of the letter. Click the color box to change the color.
  – **Background color.** Sets the background color of the residues. Click the color box to change the color.

- **Polarity colors (only protein).** Colors the residues according to the following categories:
  – **Green** neutral, polar
  – **Black** neutral, nonpolar
  – **Red** acidic, polar
  – **Blue** basic, polar
  – As with other options, you can choose to set or change the coloring for either the residue letter or its background:
    * **Foreground color.** Sets the color of the letter. Click the color box to change the color.
    * **Background color.** Sets the background color of the residues. Click the color box to change the color.

- **Trace colors (only DNA).** Colors the residues according to the color conventions of chromatogram traces: A=green, C=blue, G=black, and T=red.
  – **Foreground color.** Sets the color of the letter.
  – **Background color.** Sets the background color of the residues.

**Nucleotide info**

These preferences only apply to nucleotide sequences.

- **Translation.** Displays a translation into protein just below the nucleotide sequence. Depending on the zoom level, the amino acids are displayed with three letters or one letter. In cases where variants are present in the reads, synonymous variants are shown in orange in the translated sequence whereas non-synonymous are shown in red.
  – **Frame.** Determines where to start the translation.
    * **ORF/CDS.** If the sequence is annotated, the translation will follow the CDS or ORF annotations. If annotations overlap, only one translation will be shown. If only one annotation is visible, the Workbench will attempt to use this annotation to mark the start and stop for the translation. In cases where this is not possible, the first annotation will be used (i.e. the one closest to the 5’ end of the sequence).
    * **Selection.** This option will only take effect when you make a selection on the sequence. The translation will start from the first nucleotide selected. Making a new selection will automatically display the corresponding translation. Read more about selecting in section 11.1.2.
• **+1 to -1.** Select one of the six reading frames.

• **All forward/All reverse.** Shows either all forward or all reverse reading frames.

• **All.** Select all reading frames at once. The translations will be displayed on top of each other.

  - **Table.** The translation table to use in the translation. For more about translation tables, see section 15.5.

  - **Only AUG start codons.** For most genetic codes, a number of codons can be start codons (TTG, CTG, or ATG). These will be colored green, unless selecting the "Only AUG start codons" option, which will result in only the AUG codons colored in green.

  - **Single letter codes.** Choose to represent the amino acids with a single letter instead of three letters.

• **Trace data.** See section 18.1.

• **Quality scores.** For sequencing data containing quality scores, the quality score information can be displayed along the sequence.

  - **Show as probabilities.** Converts quality scores to error probabilities on a 0-1 scale, i.e. not log-transformed.

  - **Foreground color.** Colors the letter using a gradient, where the left side color is used for low quality and the right side color is used for high quality. The sliders just above the gradient color box can be dragged to highlight relevant levels. The colors can be changed by clicking the box. This will show a list of gradients to choose from.

  - **Background color.** Sets a background color of the residues using a gradient in the same way as described above.

  - **Graph.** The quality score is displayed on a graph (Learn how to export the data behind the graph in section 6.8).

    • **Height.** Specifies the height of the graph.

    • **Type.** The graph can be displayed as Line plot, Bar plot or as a Color bar.

    • **Color box.** For Line and Bar plots, the color of the plot can be set by clicking the color box. For Colors, the color box is replaced by a gradient color box as described under Foreground color.

• **G/C content.** Calculates the G/C content of a part of the sequence and shows it as a gradient of colors or as a graph below the sequence.

  - **Window length.** Determines the length of the part of the sequence to calculate. A window length of 9 will calculate the G/C content for the nucleotide in question plus the 4 nucleotides to the left and the 4 nucleotides to the right. A narrow window will focus on small fluctuations in the G/C content level, whereas a wider window will show fluctuations between larger parts of the sequence.

  - **Foreground color.** Colors the letter using a gradient, where the left side color is used for low levels of G/C content and the right side color is used for high levels of G/C content. The sliders just above the gradient color box can be dragged to highlight relevant levels of G/C content. The colors can be changed by clicking the box. This will show a list of gradients to choose from.

  - **Background color.** Sets a background color of the residues using a gradient in the same way as described above.
Graph. The G/C content level is displayed on a graph (Learn how to export the data behind the graph in section 6.8).

- Height. Specifies the height of the graph.
- Type. The graph can be displayed as Line plot, Bar plot or as a Color bar.
- Color box. For Line and Bar plots, the color of the plot can be set by clicking the color box. For Colors, the color box is replaced by a gradient color box as described under Foreground color.

- Secondary structure. Allows you to choose how to display a symbolic representation of the secondary structure along the sequence.

See section 22.2.3 for a detailed description of the settings.

Protein info

These preferences only apply to proteins. The first nine items are different hydrophobicity scales. These are described in section 16.3.1.

- Kyte-Doolittle. The Kyte-Doolittle scale is widely used for detecting hydrophobic regions in proteins. Regions with a positive value are hydrophobic. This scale can be used for identifying both surface-exposed regions as well as transmembrane regions, depending on the window size used. Short window sizes of 5-7 generally work well for predicting putative surface-exposed regions. Large window sizes of 19-21 are well suited for finding transmembrane domains if the values calculated are above 1.6 [Kyte and Doolittle, 1982]. These values should be used as a rule of thumb and deviations from the rule may occur.

- Cornette. Cornette et al. computed an optimal hydrophobicity scale based on 28 published scales [Cornette et al., 1987]. This optimized scale is also suitable for prediction of alpha-helices in proteins.

- Engelman. The Engelman hydrophobicity scale, also known as the GES-scale, is another scale which can be used for prediction of protein hydrophobicity [Engelman et al., 1986]. As the Kyte-Doolittle scale, this scale is useful for predicting transmembrane regions in proteins.

- Eisenberg. The Eisenberg scale is a normalized consensus hydrophobicity scale which shares many features with the other hydrophobicity scales [Eisenberg et al., 1984].

- Rose. The hydrophobicity scale by Rose et al. is correlated to the average area of buried amino acids in globular proteins [Rose et al., 1985]. This results in a scale which is not showing the helices of a protein, but rather the surface accessibility.

- Janin. This scale also provides information about the accessible and buried amino acid residues of globular proteins [Janin, 1979].

- Hopp-Woods. Hopp and Woods developed their hydrophobicity scale for identification of potentially antigenic sites in proteins. This scale is basically a hydrophilic index where apolar residues have been assigned negative values. Antigenic sites are likely to be predicted when using a window size of 7 [Hopp and Woods, 1983].
• **Welling.** [Welling et al., 1985] Welling et al. used information on the relative occurrence of amino acids in antigenic regions to make a scale which is useful for prediction of antigenic regions. This method is better than the Hopp-Woods scale of hydrophobicity which is also used to identify antigenic regions.

• **Kolaskar-Tongaonkar.** A semi-empirical method for prediction of antigenic regions has been developed [Kolaskar and Tongaonkar, 1990]. This method also includes information of surface accessibility and flexibility and at the time of publication the method was able to predict antigenic determinants with an accuracy of 75%.

• **Surface Probability.** Display of surface probability based on the algorithm by [Emini et al., 1985]. This algorithm has been used to identify antigenic determinants on the surface of proteins.

• **Chain Flexibility.** Display of backbone chain flexibility based on the algorithm by [Karplus and Schulz, 1985]. It is known that chain flexibility is an indication of a putative antigenic determinant.

**Find**

The Find function can be used for searching the sequence and is invoked by pressing Ctrl + Shift + F (Ctrl + Shift + F on Mac). Initially, specify the 'search term' to be found, select the type of search (see various options in the following) and finally click on the Find button. The first occurrence of the search term will then be highlighted. Clicking the find button again will find the next occurrence and so on. If the search string is found, the corresponding part of the sequence will be selected.

• **Search term.** Enter the text or number to search for. The search function does not discriminate between lower and upper case characters.

• **Sequence search.** Search the nucleotides or amino acids. For amino acids, the single letter abbreviations should be used for searching. The sequence search also has a set of advanced search parameters:
  
  – Include negative strand. This will search on the negative strand as well.
  
  – Treat ambiguous characters as wildcards in search term. If you search for e.g. ATN, you will find both ATG and ATC. If you wish to find literally exact matches for ATN (i.e. only find ATN - not ATG), this option should not be selected.
  
  – Treat ambiguous characters as wildcards in sequence. If you search for e.g. ATG, you will find both ATG and ATN. If you have large regions of Ns, this option should not be selected.

Note that if you enter a position instead of a sequence, it will automatically switch to position search.

• **Annotation search.** Searches the annotations on the sequence. The search is performed both on the labels of the annotations, but also on the text appearing in the tooltip that you see when you keep the mouse cursor fixed. If the search term is found, the part of the sequence corresponding to the matching annotation is selected. The option "Include translations" means that you can choose to search for translations which are part of
an annotation (in some cases, CDS annotations contain the amino acid sequence in a "/translation" field). But it will not dynamically translate nucleotide sequences, nor will it search the translations that can enabled using the "Nucleotide info" side panel.

- **Position search.** Finds a specific position on the sequence. In order to find an interval, e.g. from position 500 to 570, enter "500..570" in the search field. This will make a selection from position 500 to 570 (both included). Notice the two periods (..) between the start and end number. If you enter positions including thousands separators like 123,345, the comma will just be ignored and it would be equivalent to entering 123345.

- **Include negative strand.** When searching the sequence for nucleotides or amino acids, you can search on both strands.

- **Name search.** Searches for sequence names. This is useful for searching sequence lists and mapping results for example.

This concludes the description of the View Preferences. Next, the options for selecting and editing sequences are described.

**Text format**

These preferences allow you to adjust the format of all the text in the view (both residue letters, sequence name and translations if they are shown).

- **Text size.** Five different sizes.
- **Font.** Shows a list of Fonts available on your computer.
- **Bold residues.** Makes the residues bold.

**Restriction sites in the Side Panel**

Please see section 19.1.1.

### 11.1.2 Selecting parts of the sequence

You can select parts of a sequence:

*Click Selection (mouse icon) in Toolbar | Press and hold down the mouse button on the sequence where you want the selection to start | move the mouse to the end of the selection while holding the button | release the mouse button*

Alternatively, you can search for a specific interval using the find function described above.

If you have made a selection and wish to adjust it:

*drag the edge of the selection (you can see the mouse cursor change to a horizontal arrow*  
*or press and hold the Shift key while using the right and left arrow keys to adjust the right side of the selection.*  

If you wish to select the entire sequence:

*double-click the sequence name to the left*
Selecting several parts at the same time (multiselect) You can select several parts of sequence by holding down the Ctrl button while making selections. Holding down the Shift button lets you extend or reduce an existing selection to the position you clicked.

To select a part of a sequence covered by an annotation:

right-click the annotation | Select annotation

or double-click the annotation

To select a fragment between two restriction sites that are shown on the sequence:

double-click the sequence between the two restriction sites

(Read more about restriction sites in section 11.1.1.)

Open a selection in a new view A selection can be opened in a new view and saved as a new sequence:

right-click the selection | Open selection in New View

This opens the annotated part of the sequence in a new view. The new sequence can be saved by dragging the tab of the sequence view into the Navigation Area.

The process described above is also the way to manually translate coding parts of sequences (CDS) into protein. You simply translate the new sequence into protein. This is done by:

right-click the tab of the new sequence | Toolbox | Classical Sequence Analysis | Nucleotide Analysis | Translate to Protein

A selection can also be copied to the clipboard and pasted into another program:

make a selection | Ctrl + C (⌘ + C on Mac)

Note! The annotations covering the selection will not be copied.

A selection of a sequence can be edited as described in the following section.

11.1.3 Editing the sequence

When you make a selection, it can be edited by:

right-click the selection | Edit Selection

A dialog appears displaying the sequence. You can add, remove or change the text and click OK. The original selected part of the sequence is now replaced by the sequence entered in the dialog. This dialog also allows you to paste text into the sequence using Ctrl + V (⌘ + V on Mac).

If you delete the text in the dialog and press OK, the selected text on the sequence will also be deleted. Another way to delete a part of the sequence is to:

right-click the selection | Delete Selection

If you wish to correct only one residue, this is possible by simply making the selection cover only one residue and then type the new residue.

Another way to edit the sequence is by inserting a restriction site. See section 19.3.4.
Note When editing annotated nucleotide sequences, the annotation content is not updated automatically (but its position is). Please refer to section 11.3.3 for details on annotation editing.

Before exporting annotated nucleotide sequences in GenBank format, ensure that the annotations in the Annotations Table reflect the edits that have been made to the sequence.

### 11.1.4 Sequence region types

The various annotations on sequences cover parts of the sequence. Some cover an interval, some cover intervals with unknown endpoints, some cover more than one interval etc. In the following, all of these will be referred to as **regions**. Regions are generally illustrated by markings (often arrows) on the sequences. An arrow pointing to the right indicates that the corresponding region is located on the positive strand of the sequence. Figure 11.2 is an example of three regions with separate colors.

![Figure 11.2: Three regions on a human beta globin DNA sequence (HUMHBB).](image)

Figure 11.3 shows an artificial sequence with all the different kinds of regions.

![Figure 11.3: Region #1: A single residue, Region #2: A range of residues including both endpoints, Region #3: A range of residues starting somewhere before 30 and continuing up to and including 40, Region #4: A single residue somewhere between 50 and 60 inclusive, Region #5: A range of residues beginning somewhere between 70 and 80 inclusive and ending at 90 inclusive, Region #6: A range of residues beginning somewhere between 100 and 110 inclusive and ending somewhere between 120 and 130 inclusive, Region #7: A site between residues 140 and 141, Region #8: A site between two residues somewhere between 150 and 160 inclusive, Region #9: A region that covers ranges from 170 to 180 inclusive and 190 to 200 inclusive, Region #10: A region on negative strand that covers ranges from 210 to 220 inclusive, Region #11: A region on negative strand that covers ranges from 230 to 240 inclusive and 250 to 260 inclusive.](image)
11.2 Circular DNA

A sequence can be shown as a circular molecule:

Select a sequence in the Navigation Area and right-click on the file name | Hold the mouse over "Show" to enable a list of options | Select "Circular View" (enido)

or If the sequence is already open | Click "Show Circular View" (enido) at the lower left part of the view

This will open a view of the molecule similar to the one in figure 11.4.

Figure 11.4: A molecule shown in a circular view.

This view of the sequence shares some of the properties of the linear view of sequences as described in section 11.1, but there are some differences. The similarities and differences are listed below:

- **Similarities:**
  - The editing options.
  - Options for adding, editing and removing annotations.
  - Restriction Sites, Annotation Types, Find and Text Format preferences groups.

- **Differences:**
  - In the Sequence Layout preferences, only the following options are available in the circular view: Numbers on plus strand, Numbers on sequence and Sequence label.
  - You cannot zoom in to see the residues in the circular molecule. If you wish to see these details, split the view with a linear view of the sequence.
  - In the Annotation Layout, you also have the option of showing the labels as Stacked. This means that there are no overlapping labels and that all labels of both annotations and restriction sites are adjusted along the left and right edges of the view.

11.2.1 Using split views to see details of the circular molecule

In order to see the nucleotides of a circular molecule you can open a new view displaying a circular view of the molecule:

Press and hold the Ctrl button (on Mac) | click Show Sequence (enido) at the bottom of the view
This will open a linear view of the sequence below the circular view. When you zoom in on the linear view you can see the residues as shown in figure 11.5.

**Note!** If you make a selection in one of the views, the other view will also make the corresponding selection, providing an easy way for you to focus on the same region in both views.

### 11.2.2 Mark molecule as circular and specify starting point

You can mark a DNA molecule as circular or linear by right-clicking on its name in either the Sequence view or the Circular view. If the sequence is linear, you will see the option to mark it as circular and vice versa (see figure 11.6).
In the Sequence view, a sequence marked as circular is indicated by the use of double angle brackets at the start and end of the sequence. The linear or circular status of a sequence can also be seen in the Locus line of the Text view for a Sequence, or in the Linear column of the Table view of a Sequence List.

The starting point of a circular sequence can be changed by selecting the position of the new starting point and right-clicking on that selection to choose the option **Move Starting Point to Selection Start** (figure 11.7).

![Figure 11.7: Right-click on a circular sequence to move the starting point to the selected position.](image)

### 11.3 Working with annotations

Annotations provide information about specific regions of a sequence.

A typical example is the annotation of a gene on a genomic DNA sequence.

Annotations derive from different sources:

- Sequences downloaded from databases like GenBank are annotated.
- In some of the data formats that can be imported into *CLC Genomics Workbench*, sequences can have annotations (GenBank, EMBL and Swiss-Prot format).
The result of a number of analyses in CLC Genomics Workbench are annotations on the sequence (e.g. finding open reading frames and restriction map analysis).

A protein structure can be linked with a sequence (section 13.4.2), and atom groups defined on the structure transferred to sequence annotations or vica versa (section 13.4.3).

You can manually add annotations to a sequence (described in the section 11.3.2).

If you would like to extract parts of a sequence (or several sequences) based on its annotations, you can find a description of how to do this in section 32.2.

Note! Annotations are included if you export the sequence in GenBank, Swiss-Prot, EMBL or CLC format. When exporting in other formats, annotations are not preserved in the exported file.

### 11.3.1 Viewing annotations

Annotations can be viewed in a number of different ways:

- As arrows or boxes in all views displaying sequences (sequence lists, alignments etc)
- In the table of annotations
- In the text view of sequences

In the following sections, these view options will be described in more detail.

In all the views except the text view, annotations can be added, modified and deleted. This is described in the following sections.

#### View Annotations in sequence views

Figure 11.8 shows an annotation displayed on a sequence.

![Figure 11.8: An annotation showing a coding region on a genomic dna sequence.](image)

The various sequence views listed in section 11.3.1 have different default settings for showing annotations. However, they all have two groups in the Side Panel in common:

- **Annotation Layout**
- **Annotation Types**
The two groups are shown in figure 11.9.

In the **Annotation layout** group, you can specify how the annotations should be displayed (notice that there are some minor differences between the different sequence views):

- **Show annotations.** Determines whether the annotations are shown.

- **Position.**
  - **On sequence.** The annotations are placed on the sequence. The residues are visible through the annotations (if you have zoomed in to 100%).
  - **Next to sequence.** The annotations are placed above the sequence.
  - **Separate layer.** The annotations are placed above the sequence and above restriction sites (only applicable for nucleotide sequences).

- **Offset.** If several annotations cover the same part of a sequence, they can be spread out.
  - **Piled.** The annotations are piled on top of each other. Only the one at front is visible.
  - **Little offset.** The annotations are piled on top of each other, but they have been offset a little.
  - **More offset.** Same as above, but with more spreading.
  - **Most offset.** The annotations are placed above each other with a little space between. This can take up a lot of space on the screen.

- **Label.** The name of the annotation can shown as a label. Additional information about the sequence is shown if you place the mouse cursor on the annotation and keep it still.
  - **No labels.** No labels are displayed.
  - **On annotation.** The labels are displayed in the annotation’s box.
  - **Over annotation.** The labels are displayed above the annotations.
  - **Before annotation.** The labels are placed just to the left of the annotation.
  - **Flag.** The labels are displayed as flags at the beginning of the annotation.
Stacked. The labels are offset so that the text of all labels is visible. This means that there is varying distance between each sequence line to make room for the labels.

- **Show arrows.** Displays the end of the annotation as an arrow. This can be useful to see the orientation of the annotation (for DNA sequences). Annotations on the negative strand will have an arrow pointing to the left.

- **Use gradients.** Fills the boxes with gradient color.

In the **Annotation types** group, you can choose which kinds of annotations that should be displayed. This group lists all the types of annotations that are attached to the sequence(s) in the view. For sequences with many annotations, it can be easier to get an overview if you deselect the annotation types that are not relevant.

Unchecking the checkboxes in the **Annotation layout** will not remove this type of annotations from the sequence - it will just hide them from the view.

Besides selecting which types of annotations that should be displayed, the **Annotation types** group is also used to change the color of the annotations on the sequence. Click the colored square next to the relevant annotation type to change the color.

This will display a dialog with five tabs: Swatches, HSB, HSI, RGB, and CMYK. They represent five different ways of specifying colors. Apply your settings and click **OK**. When you click **OK**, the color settings cannot be reset. The **Reset** function only works for changes made before pressing **OK**.

Furthermore, the **Annotation types** can be used to easily browse the annotations by clicking the small button ( ) next to the type. This will display a list of the annotations of that type (see figure 11.10).

![Figure 11.10: Browsing the gene annotations on a sequence.](image)

Clicking an annotation in the list will select this region on the sequence. In this way, you can quickly find a specific annotation on a long sequence.

Note: A waved end on an annotation (figure 11.11) means that the annotation is torn, i.e., it extends beyond the sequence displayed. An annotation can be torn when a new, smaller sequence has been created from a larger sequence. A common example of this situation is when you select a section of a stand-alone sequence and open it in a new view. If there are annotations present within this selected region that extend beyond the selection, then the selected sequence shown in the new view will exhibit these torn annotations.
View Annotations in a table

Annotations can also be viewed in a table:

- Select a sequence in the Navigation Area and right-click on the file name | Hold the mouse over "Show" to enable a list of options | Annotation Table ()
- or If the sequence is already open | Click Show Annotation Table () at the lower left part of the view

This will open a view similar to the one in figure 11.12).

In the Side Panel you can show or hide individual annotation types in the table. E.g. if you only wish to see "gene" annotations, de-select the other annotation types so that only "gene" is selected.

Each row in the table is an annotation which is represented with the following information:

- Name.
- Type.
- Region.
- Qualifiers.
The Name, Type and Region for each annotation can be edited simply by double-clicking, typing the change directly, and pressing Enter.

This information corresponds to the information in the dialog when you edit and add annotations (see section 11.3.2).

You can benefit from this table in several ways:

- It provides an intelligible overview of all the annotations on the sequence.
- You can use the filter at the top to search the annotations. Type e.g. "UCP" into the filter and you will find all annotations which have "UCP" in either the name, the type, the region or the qualifiers. Combined with showing or hiding the annotation types in the Side Panel, this makes it easy to find annotations or a subset of annotations.
- You can copy and paste annotations, e.g. from one sequence to another.
- If you wish to edit many annotations consecutively, the double-click editing makes this very fast (see section 11.3.2).

### 11.3.2 Adding annotations

Adding annotations to a sequence can be done in two ways:

**Open the sequence in a sequence view (double-click in the Navigation Area) | make a selection covering the part of the sequence you want to annotate | right-click the selection | Add Annotation**

**or** **Select a sequence in the Navigation Area and right-click on the file name | Hold the mouse over "Show" to enable a list of options | Annotation table | right click anywhere in the annotation table | select Add Annotation**

This will display a dialog like the one in figure 11.13.

The left-hand part of the dialog lists a number of Annotation types. When you have selected an annotation type, it appears in Type to the right. You can also select an annotation directly in this list. Choosing an annotation type is mandatory. If you wish to use an annotation type which is not present in the list, simply enter this type into the Type field

The right-hand part of the dialog contains the following text fields:

- **Name.** The name of the annotation which can be shown on the label in the sequence views. (Whether the name is actually shown depends on the Annotation Layout preferences, see section 11.3.1).

- **Type.** Reflects the left-hand part of the dialog as described above. You can also choose directly in this list or type your own annotation type.

- **Region.** If you have already made a selection, this field will show the positions of the selection. You can modify the region further using the conventions of DDBJ, EMBL

---

1(See section 2.2.3 on how to make selections that are not contiguous.)

2Note that your own annotation types will be converted to "unsure" when exporting in GenBank format. As long as you use the sequence in CLC format, your own annotation type will be preserved
and GenBank. The following are examples of how to use the syntax (based on http://www.ncbi.nlm.nih.gov/collab/FT):

- **467.** Points to a single residue in the presented sequence.
- **340..565.** Points to a continuous range of residues bounded by and including the starting and ending residues.
- **<345..500.** Indicates that the exact lower boundary point of a region is unknown. The location begins at some residue previous to the first residue specified (which is not necessarily contained in the presented sequence) and continues up to and including the ending residue.
- **<1..888.** The region starts before the first sequenced residue and continues up to and including residue 888.
- **1..>888.** The region starts at the first sequenced residue and continues beyond residue 888.
- **(102.110).** Indicates that the exact location is unknown, but that it is one of the residues between residues 102 and 110, inclusive.
- **123..124.** Points to a site between residues 123 and 124.
- **join(12..78,134..202).** Regions 12 to 78 and 134 to 202 should be joined to form one contiguous sequence.
- **complement(34..126).** Start at the residue complementary to 126 and finish at the residue complementary to residue 34 (the region is on the strand complementary to the presented strand).
- **complement(join(2691..4571,4918..5163)).** Joins regions 2691 to 4571 and 4918 to 5163, then complements the joined segments (the region is on the strand complementary to the presented strand).
- **join(complement(4918..5163),complement(2691..4571)).** Complements regions 4918 to 5163 and 2691 to 4571, then joins the complemented segments (the region is on the strand complementary to the presented strand).
• **Annotations.** In this field, you can add more information about the annotation like comments and links. Click the **Add qualifier/key** button to enter information. Select a qualifier which describes the kind of information you wish to add. If an appropriate qualifier is not present in the list, you can type your own qualifier. The pre-defined qualifiers are derived from the GenBank format. You can add as many qualifier/key lines as you wish by clicking the button. Redundant lines can be removed by clicking the delete icon (delete icon). The information entered on these lines is shown in the annotation table (see section 11.3.1) and in the yellow box which appears when you place the mouse cursor on the annotation. If you write a hyperlink in the Key text field, like e.g. "www.qiagenbioinformatics.com", it will be recognized as a hyperlink. Clicking the link in the annotation table will open a web browser.

Click **OK** to add the annotation.

**Note!** The annotation will be included if you export the sequence in GenBank, Swiss-Prot or CLC format. When exporting in other formats, annotations are not preserved in the exported file.

### 11.3.3 Edit annotations

To edit an existing annotation from within a sequence view:

right-click the annotation | **Edit Annotation**

This will show the same dialog as in figure 11.13, with the exception that some of the fields are filled out depending on how much information the annotation contains.

There is another way of quickly editing annotations which is particularly useful when you wish to edit several annotations.

To edit the information, simply double-click and you will be able to edit e.g. the name or the annotation type. If you wish to edit the qualifiers and double-click in this column, you will see the dialog for editing annotations.

**Advanced editing of annotations**

Sometimes you end up with annotations which do not have a meaningful name. In that case there is an advanced batch rename functionality:

Open the Annotation Table | select the annotations that you want to rename | right-click the selection | **Advanced Rename**

This will bring up the dialog shown in figure 11.14.
In this dialog, you have two options:

- **Use this qualifier.** Use one of the qualifiers as name. A list of all qualifiers of all the selected annotations is shown. Note that if one of the annotations do not have the qualifier you have chosen, it will not be renamed. If an annotation has multiple qualifiers of the same type, the first is used for naming.

- **Use annotation type as name.** The annotation’s type will be used as name (e.g. if you have an annotation of type “Promoter”, it will get "Promoter" as its name by using this option).

A similar functionality for batch re-typing annotations is available in the right-click menu as well, in case your annotations are not typed correctly:

Open the Annotation Table | select the annotations that you want to retype | right-click the selection | Advanced Retype

This will bring up the dialog shown in figure **11.15**.

![Figure 11.15: The Advanced Retype dialog.](image11.15)

In this dialog, you have two options:

- **Use this qualifier.** Use one of the qualifiers as type. A list of all qualifiers of all the selected annotations is shown. Note that if one of the annotations do not have the qualifier you have chosen, it will not be retyped. If an annotation has multiple qualifiers of the same type, the first is used for the new type.

- **New type.** You can select from a list of all the pre-defined types as well as enter your own annotation type. All the selected annotations will then get this type.

- **Use annotation name as type.** The annotation’s name will be used as type (e.g. if you have an annotation named “Promoter”, it will get "Promoter" as its type by using this option).

### 11.3.4 Removing annotations

Annotations can be hidden using the **Annotation Types** preferences in the **Side Panel** to the right of the view (see section **11.3.1**). In order to completely remove the annotation:

right-click the annotation | Delete Annotation

If you want to remove all annotations of one type:
right-click an annotation of the type you want to remove | Delete | Delete Annotations of Type "type"

If you want to remove all annotations from a sequence:

right-click an annotation | Delete | Delete All Annotations

The removal of annotations can be undone using Ctrl + Z or Undo (ностей) in the Toolbar.

If you have more sequences (e.g. in a sequence list, alignment or contig), you have two additional options:

right-click an annotation | Delete | Delete All Annotations from All Sequences

right-click an annotation | Delete | Delete Annotations of Type "type" from All Sequences

11.4 Element information

The normal view of a sequence (by double-clicking) shows the annotations as boxes along the sequence, but often there is more information available about sequences. This information is available through the Element info view.

To view the sequence information:

Select a sequence in the Navigation Area and right-click on the file name | Hold the mouse over "Show" to enable a list of options | Element Info (뜻)

Another way to show the text view is to open the sequence in the View Area and click on the "Show Element Info" icon (뜻) found at the bottom of the window.

This will display a view similar to fig 11.16.

Figure 11.16: The initial display of sequence info for the HUMHBB DNA sequence from the Example data.

All the lines in the view are headings, and the corresponding text can be shown by clicking the text. The information available depends on the origin of the sequence.
• **Name.** The name of the sequence which is also shown in sequence views and in the Navigation Area.

• **Description.** A description of the sequence.

• **Metadata.** The Metadata table and the detailed metadata values associated with the sequence.

• **Comments.** The author’s comments about the sequence.

• **Keywords.** Keywords describing the sequence.

• **Db source.** Accession numbers in other databases concerning the same sequence.

• **Gb Division.** Abbreviation of GenBank divisions. See section 3.3 in the GenBank release notes for a full list of GenBank divisions.

• **Length.** The length of the sequence.

• **Modification date.** Modification date from the database. This means that this date does not reflect your own changes to the sequence. See section 2.1.2 for information about the latest changes to the sequence after it was downloaded from the database.

• **Latin name.** Latin name of the organism.

• **Common name.** Scientific name of the organism.

• **Taxonomy name.** Taxonomic classification levels.

• **Read group** Read group identifier "ID", technology used to produced the reads "Platform", and sample name "Sample".

• **Paired Status.** Unpaired or Paired sequences, with in this case the Minimum and Maximum distances as well as the Read orientation set during import.

Some of the information can be edited by clicking the blue Edit text. This means that you can add your own information to sequences that do not derive from databases.

### 11.5 View as text

A sequence can be viewed as text without any layout and text formatting. This displays all the information about the sequence in the GenBank file format. To view a sequence as text:

Select a sequence in the Navigation Area and right-click on the file name | Hold the mouse over "Show" to enable a list of options | Select "Text View" ( 

Another way to show the text view is to open the sequence in the View Area and click on the "Show Text View" icon ( ) found at the bottom of the window.

This makes it possible to see background information about e.g. the authors and the origin of DNA and protein sequences. Selections or the entire text of the Sequence Text View can be copied and pasted into other programs:

Much of the information is also displayed in the Sequence info, where it is easier to get an overview (see section 11.4.)

In the Side Panel, you find a search field for searching the text in the view.
11.6 Sequence Lists

The **Sequence List** is a file containing a number of sequences. Having sequences in a sequence list can help organizing sequence data. A Sequence List can be displayed in a graphical sequence view or in a tabular format. The two different views of the same sequence list are shown in split screen in figure 11.17.

![Sequence List](image)

Figure 11.17: A sequence list containing multiple sequences can be viewed in either a table or in a graphical sequence list. The graphical view is useful for viewing annotations and the sequence itself, while the table view provides other information like sequence lengths, and the number of sequences in the list (number of Rows reported).

The **graphical view of sequence lists** is almost identical to the view of single sequences (see section 11.1). The main difference is that you now can see more than one sequence in the same view, and additionally have a few extra options for sorting, deleting and adding sequences:

- To add extra sequences to the list, right-click an empty (white) space in the view, and select **Add Sequences**.
- To delete a sequence from the list, right-click the sequence’s name and select **Delete Sequence**.
- To sort the sequences in the list, right-click the name of one of the sequences and select **Sort Sequence List by Name** or **Sort Sequence List by Length**.
- To rename a sequence, right-click the name of the sequence and select **Rename Sequence**.

Each sequence in the **table sequence list** is displayed with:
- Name
- Accession
- Description
- Modification date
- Length
- First 50 residues

The number of sequences in the list is reported as the number of Rows at the top of the table view. Adding and removing sequences from the list is easy: adding is done by dragging the sequence from another list or from the Navigation Area and drop it in the table. To delete sequences, simply select them and press **Delete**. To extract a sequence from a sequence list, drag the sequence directly from the table into the Navigation Area. Another option is to extract all sequences found in the list using the **Extract Sequences** tool. A description of how to use the **Extract Sequences** tool can be found in section 14.2.

Sequence lists are generated automatically when you import files containing more than one sequence. They may also be created as the output from particular Workbench tool, including database searches. For more information about creating sequence lists from a database search, see (chapter 7.1).

You can create a subset of a Sequence List: select the relevant sequences, right-click on the selected elements and choose **Create New Sequence List** from the drop down menu. This will generate a new sequence list that only includes the selected sequences.

A **Sequence List** can also be created from single sequences or by merging already existing sequence lists with the Workbench. To do this, select two or more sequences or sequence lists in the Navigation Area, right click on the selected elements and choose

**New | Sequence List**

Alternatively, you can launch this tool via the "File" menu system.

This opens the **Sequence List** Wizard (figure 11.18). The dialog allows you to select more sequences to include in the list, or to remove already chosen sequences from the list.

If you are trying to create a new sequence list from a mixture of paired and unpaired datasets,
A warning message will let you know that the resulting sequence list will be set as unpaired (figure 11.19).

![Figure 11.19: A warning appears when trying to create a new sequence list from a mixture of paired and unpaired datasets.](image)

This warning also appears when trying to create a Sequence List out of paired reads lists for which the Minimum and Maximum distances are different between lists. If that is the case, distances can be edited to be similar for all lists that needs to be merged in a new one.

For this, open all Sequence Lists one after the other and click on the Show Element Info icon at the bottom of the view (figure 11.20). Edit the distances by clicking on the button "Edit" next to the entry "Paired status" and click OK. Save the Sequence lists with the edited Paired statuses before attempting to create a merged sequence List. This final list’s status will be set as Paired reads.

![Figure 11.20: Edit the Minimum and Maximum distances of several sequence lists to be able to merge them into one.](image)

CLC Genomics Workbench offers to conduct BLAST searches on protein and DNA sequences. In short, a BLAST search identifies homologous sequences between your input (query) query sequence and a database of sequences [McGinnis and Madden, 2004]. BLAST (Basic Local Alignment Search Tool), identifies homologous sequences using a heuristic method which finds short matches between two sequences. After initial match BLAST attempts to start local alignments from these initial matches.
If you are interested in the bioinformatics behind BLAST, there is an easy-to-read explanation of this in section 12.5.

Figure 12.8 shows an example of a BLAST result in the CLC Genomics Workbench.

Figure 12.1: Display of the output of a BLAST search. At the top is there a graphical representation of BLAST hits with tool-tips showing additional information on individual hits. Below is a tabular form of the BLAST results.

12.1 Running BLAST searches

With the CLC Genomics Workbench there are two ways of performing BLAST searches: You can either have the BLAST process run on NCBI’s BLAST servers (http://www.ncbi.nlm.nih.gov/) or you can perform the BLAST search on your own computer.

The advantage of running the BLAST search on NCBI servers is that you have readily access to the popular, and often very large, BLAST databases without having to download them to your own computer. The advantages of running BLAST on your own computer include that you can use your own sequence collections as blast databases, and that running big batch BLAST jobs can be faster and more reliable when done locally.

12.1.1 BLAST at NCBI

When running a BLAST search at the NCBI, the Workbench sends the sequences you select to the NCBI’s BLAST servers. When the results are ready, they will be automatically downloaded and displayed in the Workbench. When you enter a large number of sequences for searching with BLAST, the Workbench automatically splits the sequences up into smaller subsets and sends one subset at the time to NCBI. This is to avoid exceeding any internal limits the NCBI places on the number of sequences that can be submitted to them for BLAST searching. The size of the subset created in the CLC software depends both on the number and size of the sequences.

To start a BLAST job to search your sequences against databases held at the NCBI, go to:

Toolbox | BLAST ( ) | BLAST at NCBI ( )

Alternatively, use the keyboard shortcut: Ctrl+Shift+B for Windows and ⌘ +Shift+B on Mac OS.

This opens the dialog seen in figure 12.2

Select one or more sequences of the same type (either DNA or protein) and click Next.
In this dialog, you choose which type of BLAST search to conduct, and which database to search against (figure 12.3). The databases at the NCBI listed in the dropdown box will correspond to the query sequence type you have, DNA or protein, and the type of blast search you can chose among to run. A complete list of these databases can be found in Appendix B. Here you can also read how to add additional databases available the NCBI to the list provided in the dropdown menu.

**BLAST programs for DNA query sequences:**

- **blastn: DNA sequence against a DNA database.** Searches for DNA sequences with homologous regions to your nucleotide query sequence.

- **blastx: Translated DNA sequence against a Protein database.** Automatic translation of your DNA query sequence in six frames; these translated sequences are then used to search a protein database.

- **tblastx: Translated DNA sequence against a Translated DNA database.** Automatic translation of your DNA query sequence and the DNA database, in six frames. The resulting peptide query sequences are used to search the resulting peptide database. Note that this type of search is computationally intensive.

**BLAST programs for protein query sequences:**

- **blastp: Protein sequence against Protein database.** Used to look for peptide sequences with homologous regions to your peptide query sequence.

- **tblastn: Protein sequence against Translated DNA database.** Peptide query sequences are searched against an automatically translated, in six frames, DNA database.
If you search against the Protein Data Bank protein database, homologous sequences are found to the query sequence. These can be downloaded and opened with the 3D view.

Click Next.

This window, see figure 12.4, allows you to choose parameters to tune your BLAST search, to meet your requirements.

![Figure 12.4: Parameters that can be set before submitting a BLAST search.](image)

When choosing blastx or tblastx to conduct a search, you get the option of selecting a translation table for the genetic code. The standard genetic code is set as default. This setting is particularly useful when working with organisms or organelles that have a genetic code different from the standard genetic code.

- **Limit by Entrez query.** BLAST searches can be limited to the results of an Entrez query against the database chosen. This can be used to limit searches to subsets of entries in the BLAST databases. Any terms can be entered that would normally be allowed in an Entrez search session. More information about Entrez queries can be found at [http://www.ncbi.nlm.nih.gov/books/NBK3837/#EntrezHelp.Entrez_Searching_Options](http://www.ncbi.nlm.nih.gov/books/NBK3837/#EntrezHelp.Entrez_Searching_Options). The syntax described there is the same as would be accepted in the CLC interface. Some commonly used Entrez queries are pre-entered and can be chosen in the drop down menu.

- **Choose filter.** You can choose to apply Low-complexity. Mask off segments of the query sequence that have low compositional complexity. Filtering can eliminate statistically significant, but biologically uninteresting reports from the BLAST output (e.g., hits against common acidic-, basic- or proline-rich regions), leaving the more biologically interesting regions of the query sequence available for specific matching against database sequences.

- **Expect.** The threshold for reporting matches against database sequences: the default value is 10, meaning that under the circumstances of this search, 10 matches are expected to be found merely by chance according to the stochastic model of Karlin and Altschul (1990). Details of how E-values are calculated can be found at the NCBI: [http://www.ncbi.nlm.nih.gov/BLAST/tutorial/Altschul-1.html](http://www.ncbi.nlm.nih.gov/BLAST/tutorial/Altschul-1.html). If the E-value ascribed to a match is greater than the EXPECT threshold, the match will not be reported. Lower EXPECT thresholds are more stringent, leading to fewer chance matches being reported. Increasing
the threshold results in more matches being reported, but many may just matching by chance, not due to any biological similarity. Values of E less than one can be entered as decimals, or in scientific notation. For example, 0.001, 1e-3 and 10e-4 would be equivalent and acceptable values.

- **Word Size.** BLAST is a heuristic that works by finding word-matches between the query and database sequences. You may think of this process as finding “hot-spots” that BLAST can then use to initiate extensions that might lead to full-blown alignments. For nucleotide-nucleotide searches (i.e. "BLASTn") an exact match of the entire word is required before an extension is initiated, so that you normally regulate the sensitivity and speed of the search by increasing or decreasing the wordsize. For other BLAST searches non-exact word matches are taken into account based upon the similarity between words. The amount of similarity can be varied so that you normally uses just the wordsizes 2 and 3 for these searches.

- **Match/mismatch** A key element in evaluating the quality of a pairwise sequence alignment is the "substitution matrix", which assigns a score for aligning any possible pair of residues. The matrix used in a BLAST search can be changed depending on the type of sequences you are searching with (see the BLAST Frequently Asked Questions). Only applicable for protein sequences or translated DNA sequences.

- **Gap Cost.** The pull down menu shows the Gap Costs (Penalty to open Gap and penalty to extend Gap). Increasing the Gap Costs and Lambda ratio will result in alignments which decrease the number of Gaps introduced.

- **Max number of hit sequences.** The maximum number of database sequences, where BLAST found matches to your query sequence, to be included in the BLAST report.

The parameters you choose will affect how long BLAST takes to run. A search of a small database, requesting only hits that meet stringent criteria will generally be quite quick. Searching large databases, or allowing for very remote matches, will of course take longer.

Click **Finish** to start the tool.

**BLAST a partial sequence against NCBI** You can search a database using only a part of a sequence directly from the sequence view:

- select the sequence region to send to BLAST | right-click the selection | BLAST Selection Against NCBI

This will go directly to the dialog shown in figure 12.3 and the rest of the options are the same as when performing a BLAST search with a full sequence.

**12.1.2 BLAST against local data**

Running BLAST searches on your local machine can have several advantages over running the searches remotely at the NCBI:

- It can be faster.
- It does not rely on having a stable internet connection.
• It does not depend on the availability of the NCBI BLAST servers.
• You can use longer query sequences.
• You use your own data sets to search against.

On a technical level, CLC Genomics Workbench uses the NCBI’s blast+ software (see ftp://ftp.ncbi.nlm.nih.gov/blast/executables/blast+/LATEST/). Thus, the results of using a particular data set to search the same database with the same search parameters would give the same results, whether run locally or at the NCBI.

There are a number of options for what you can search against:

• You can create a database based on data already imported into your Workbench (see section 12.3.3)
• You can add pre-formatted databases (see section 12.3.1)
• You can use sequence data from the Navigation Area directly, without creating a database first.

To conduct a local BLAST search, go to:

**Toolbox** | **BLAST** ( ) | **BLAST** ( )

This opens the dialog seen in figure 12.5:

![Figure 12.5: Choose one or more sequences to conduct a BLAST search.](image)

Select one or more sequences of the same type (DNA or protein) and click **Next**.

This opens the dialog seen in figure 12.6:

At the top, you can choose between different BLAST programs.

**BLAST programs for DNA query sequences:**

• **blastn**: **DNA sequence against a DNA database.** Searches for DNA sequences with homologous regions to your nucleotide query sequence.

• **blastx**: **Translated DNA sequence against a Protein database.** Automatic translation of your DNA query sequence in six frames; these translated sequences are then used to search a protein database.
Figure 12.6: Choose a BLAST program and a target database.

- **tblastx**: Translated DNA sequence against a Translated DNA database. Automatic translation of your DNA query sequence and the DNA database, in six frames. The resulting peptide query sequences are used to search the resulting peptide database. Note that this type of search is computationally intensive.

**BLAST programs for protein query sequences:**

- **blastp**: Protein sequence against Protein database. Used to look for peptide sequences with homologous regions to your peptide query sequence.

- **tblastn**: Protein sequence against Translated DNA database. Peptide query sequences are searched against an automatically translated, in six frames, DNA database.

In cases where you have selected blastx or tblastx to conduct a search, you will get the option of selecting a translation table for the genetic code. The standard genetic code is set as default. This setting is particularly useful when working with organisms or organelles that have a genetic code that differs from the standard genetic code.

If you search against the Protein Data Bank database and homologous sequences are found to the query sequence, these can be downloaded and opened with the 3D Molecule Viewer (see section 13.1.3).

You then specify the target database to use:

- **Sequences**. When you choose this option, you can use sequence data from the Navigation Area as database by clicking the **Browse and select** icon ( ). A temporary BLAST database will be created from these sequences and used for the BLAST search. It is deleted afterwards. If you want to be able to click in the BLAST result to retrieve the hit sequences from the BLAST database at a later point, you should not use this option; create a create a BLAST database first, see section 12.3.3.

- **BLAST Database**. Select a database already available in one of your designated BLAST database folders. Read more in section 12.4.

When a database or a set of sequences has been selected, click **Next**.

The next dialog allows you to adjust the parameters to meet the requirements of your BLAST search (figure 12.7).
● **Number of threads.** You can specify the number of threads, which should be used if your Workbench is installed on a multi-threaded system.

● **Choose filter.** You can choose to apply **Low-complexity.** Mask off segments of the query sequence that have low compositional complexity. Filtering can eliminate statistically significant, but biologically uninteresting reports from the BLAST output (e.g. hits against common acidic-, basic- or proline-rich regions), leaving the more biologically interesting regions of the query sequence available for specific matching against database sequences.

● **Expect.** The threshold for reporting matches against database sequences: the default value is 10, meaning that under the circumstances of this search, 10 matches are expected to be found merely by chance according to the stochastic model of Karlin and Altschul (1990). Details of how E-values are calculated can be found at the NCBI: [http://www.ncbi.nlm.nih.gov/BLAST/tutorial/Altschul-1.html](http://www.ncbi.nlm.nih.gov/BLAST/tutorial/Altschul-1.html) If the E-value ascribed to a match is greater than the EXPECT threshold, the match will not be reported. Lower EXPECT thresholds are more stringent, leading to fewer chance matches being reported. Increasing the threshold results in more matches being reported, but many may just matching by chance, not due to any biological similarity. Values of E less than one can be entered as decimals, or in scientific notation. For example, 0.001, 1e-3 and 10e-4 would be equivalent and acceptable values.

● **Word Size.** BLAST is a heuristic that works by finding word-matches between the query and database sequences. You may think of this process as finding "hot-spots" that BLAST can then use to initiate extensions that might lead to full-blown alignments. For nucleotide-nucleotide searches (i.e. "BLASTn") an exact match of the entire word is required before an extension is initiated, so that you normally regulate the sensitivity and speed of the search by increasing or decreasing the wordsize. For other BLAST searches non-exact word matches are taken into account based upon the similarity between words. The amount of similarity can be varied so that you normally uses just the wordsizes 2 and 3 for these searches.

● **Match/mismatch** A key element in evaluating the quality of a pairwise sequence alignment is the "substitution matrix", which assigns a score for aligning any possible pair of residues. The matrix used in a BLAST search can be changed depending on the type of sequences you are searching with (see the BLAST Frequently Asked Questions). Only applicable for protein sequences or translated DNA sequences.
• **Gap Cost.** The pull down menu shows the Gap Costs (Penalty to open Gap and penalty to extend Gap). Increasing the Gap Costs and Lambda ratio will result in alignments which decrease the number of Gaps introduced.

• **Max number of hit sequences.** The maximum number of database sequences, where BLAST found matches to your query sequence, to be included in the BLAST report.

**BLAST a partial sequence against a local database** You can search a database using only a part of a sequence directly from the sequence view:

`select the region that you wish to BLAST` | `right-click the selection` | `BLAST Selection Against Local Database` ()

This will go directly to the dialog shown in figure 12.6 and the rest of the options are the same as when performing a BLAST search with a full sequence.

### 12.2 Output from BLAST searches

The output of a BLAST search is similar whether you have chosen to run your search locally or at the NCBI.

If a **single query** sequence was used, then the results will show the hits and High-Scoring Segment Pairs (HSPs) found in that database with that single sequence. If **more than one query** sequence was used, the default view of the results is a summary table, where the description of the top match found for each query sequence and the number of matches found is reported. The summary table is described in detail in section 12.2.2.

#### 12.2.1 Graphical overview for each query sequence

Double clicking on a given row of a tabular blast table opens a graphical overview of the blast results for a particular query sequence, as shown in figure figure 12.8. In cases where only one sequence was entered into a BLAST search, such a graphical overview is the default output.

Figure 12.8 shows an example of a BLAST result for an individual query sequence in the CLC Genomics Workbench.

![Figure 12.8](image_url)

**Figure 12.8:** Default display of the output of a BLAST search for one query sequence. At the top is there a graphical representation of BLAST hits with tooltips showing additional information on individual hits.
Detailed descriptions of the overview BLAST table and the graphical BLAST results view are described below.

12.2.2 Overview BLAST table

In the overview BLAST table for a multi-sequence blast search, as shown in figure 12.9, there is one row for each query sequence. Each row represents the BLAST result for this query sequence.

Double-clicking a row will open the BLAST result for this query sequence, allowing more detailed investigation of the result. You can also select one or more rows and click the Open BLAST Output button at the bottom of the view. Consensus sequence can be extracted by clicking the Extract Consensus button at the bottom. Clicking the Open Query Sequence will open a sequence list with the selected query sequences. This can be useful in work flows where BLAST is used as a filtering mechanism where you can filter the table to include e.g. sequences that have a certain top hit and then extract those.

In the overview table, the following information is shown:

- Query: Since this table displays information about several query sequences, the first column is the name of the query sequence.
- Number of HSPs: The number of High-scoring Segment Pairs (HSPs) for this query sequence.
- For the following list, the value of the best HSP is displayed together with accession number and description of this HSP, with respect to E-value, identity or positive value, hit length or bit score.
  - Lowest E-value
  - Accession (E-value)
  - Description (E-value)
  - Greatest identity %
  - Accession (identity %)
  - Description (identity %)
  - Greatest positive %
  - Accession (positive %)
  - Description (positive %)
  - Greatest HSPs length
  - Accession (HSP length)
12.2.3 BLAST graphics

The BLAST editor shows the sequences hits which were found in the BLAST search. The hit sequences are represented by colored horizontal lines, and when hovering the mouse pointer over a BLAST hit sequence, a tooltip appears, listing the characteristics of the sequence. As default, the query sequence is fitted to the window width, but it is possible to zoom in the windows and see the actual sequence alignments returned from the BLAST server.

There are several settings available in the BLAST Settings side panel.

- **Blast layout.** You can control the level of Compactness for displaying sequences:
  - **Not compact.** Full detail and spaces between the sequences.
  - **Low.** The normal settings where the residues are visible (when zoomed in) but with no extra spaces between.
  - **Medium.** The sequences are represented as lines and the residues are not visible. There is some space between the sequences.
  - **Compact.** Even less space between the sequences.

You can also choose to **Gather sequences at top.** Enabling this option affects the view that is shown when scrolling horizontally along a BLAST result. If selected, the sequence hits which did not contribute to the visible part of the BLAST graphics will be omitted whereas the found BLAST hits will automatically be placed right below the query sequence.

- **BLAST hit coloring.** You can choose whether to color hit sequences and adjust the coloring scale for visualisation of identity level.

The remaining View preferences for BLAST Graphics are the same as those of alignments. See section 11.1.

Some of the information available in the tooltips when hovering over a particular hit sequence is:

- **Name of sequence.** Here is shown some additional information of the sequence which was found. This line corresponds to the description line in GenBank (if the search was conducted on the nr database).

- **Score.** This shows the bit score of the local alignment generated through the BLAST search.

- **Expect.** Also known as the E-value. A low value indicates a homologous sequence. Higher E-values indicate that BLAST found a less homologous sequence.
• **Identities.** This number shows the number of identical residues or nucleotides in the obtained alignment.

• **Gaps.** This number shows whether the alignment has gaps or not.

• **Strand.** This is only valid for nucleotide sequences and shows the direction of the aligned strands. Minus indicate a complementary strand.

The numbers of the query and subject sequences refer to the sequence positions in the submitted and found sequences. If the subject sequence has number 59 in front of the sequence, this means that 58 residues are found upstream of this position, but these are not included in the alignment.

By right clicking the sequence name in the Graphical BLAST output it is possible to download the full hits sequence from NCBI with accompanying annotations and information. It is also possible to just open the actual hit sequence in a new view.

### 12.2.4 BLAST HSP table

In addition to the graphical display of a BLAST result, it is possible to view the BLAST results in a tabular view. In the tabular view, one can get a quick and fast overview of the results. Here you can also select multiple sequences and download or open all of these in one single step. Moreover, there is a link from each sequence to the sequence at NCBI. These possibilities are either available through a right-click with the mouse or by using the buttons below the table.

The **BLAST table** view can be shown in the following way:

*Click the Show BLAST HSP Table button at the bottom of the view*

Figure 12.10 is an example of a BLAST HSP Table.

![Figure 12.10: BLAST HSP Table. The HSPs can be sorted by the different columns, simply by clicking the column heading.](image)

The BLAST HSP Table includes the following information:

• **Query sequence.** The sequence which was used for the search.

• **HSP.** The Name of the sequences found in the BLAST search.

• **Id.** GenBank ID.

• **Description.** Text from NCBI describing the sequence.
- **E-value.** Measure of quality of the match. Higher E-values indicate that BLAST found a less homologous sequence.

- **Score.** This shows the score of the local alignment generated through the BLAST search.

- **Bit score.** This shows the bit score of the local alignment generated through the BLAST search. Bit scores are normalized, which means that the bit scores from different alignments can be compared, even if different scoring matrices have been used.

- **HSP start.** Shows the start position in the HSP sequence.

- **HSP end.** Shows the end position in the HSP sequence.

- **HSP length.** The length of the HSP.

- **Query start.** Shows the start position in the query sequence.

- **Query end.** Shows the end position in the query sequence.

- **Overlap.** Display a percentage value for the overlap of the query sequence and HSP sequence. Only the length of the local alignment is taken into account and not the full length query sequence.

- **Identity.** Shows the number of identical residues in the query and HSP sequence.

- **%Identity.** Shows the percentage of identical residues in the query and HSP sequence.

- **Positive.** Shows the number of similar but not necessarily identical residues in the query and HSP sequence.

- **%Positive.** Shows the percentage of similar but not necessarily identical residues in the query and HSP sequence.

- **Gaps.** Shows the number of gaps in the query and HSP sequence.

- **%Gaps.** Shows the percentage of gaps in the query and HSP sequence.

- **Query Frame/Strand.** Shows the frame or strand of the query sequence.

- **HSP Frame/Strand.** Shows the frame or strand of the HSP sequence.

In the **BLAST table** view you can handle the HSP sequences. Select one or more sequences from the table, and apply one of the following functions.

- **Download and Open.** Download the full sequence from NCBI and opens it. If multiple sequences are selected, they will all open (if the same sequence is listed several times, only one copy of the sequence is downloaded and opened).

- **Download and Save.** Download the full sequence from NCBI and save it. When you click the button, there will be a save dialog letting you specify a folder to save the sequences. If multiple sequences are selected, they will all open (if the same sequence is listed several times, only one copy of the sequence is downloaded and opened).

- **Open at NCBI.** Opens the corresponding sequence(s) at GenBank at NCBI. Here is stored additional information regarding the selected sequence(s). The default Internet browser is used for this purpose.
Open structure. If the HSP sequence contain structure information, the sequence is opened in a text view or a 3D view (3D view in CLC Main Workbench or CLC Genomics Workbench).

The HSPs can be sorted by the different columns, simply by clicking the column heading. In cases where individual rows have been selected in the table, the selected rows will still be selected after sorting the data.

You can do a text-based search in the information in the BLAST table by using the filter at the upper right part of the view. In this way you can search for e.g. species or other information which is typically included in the "Description" field.

The table is integrated with the graphical view described in section 12.2.3 so that selecting a HSP in the table will make a selection on the corresponding sequence in the graphical view.

12.2.5 BLAST hit table

The BLAST Hit table view can be shown in the following way:

Click the Show BLAST Hit Table button at the bottom of the view

Figure 12.11 is an example of a BLAST Hit Table.

The BLAST Hit Table includes the following information:

- **Query sequence.** The sequence which was used for the search.
- **Hit.** The Name of the sequences found in the BLAST search.
- **Id.** GenBank ID.
- **Description.** Text from NCBI describing the sequence.
- **Total Score.** Total score for all HSPs.
- **Max Score.** Maximum score of all HSPs.
- **Min E-value.** Minimum e-value of all HSPs.
CHAPTER 12. BLAST SEARCH

- **Max Bit score.** Maximum Bit score of all HSPs.
- **Max Identity.** Shows the maximum number of identical residues in the query and Hit sequence.
- **Max %Identity.** Shows the percentage of maximum identical residues in the query and Hit sequence.
- **Max Positive.** Shows the maximum number of similar but not necessarily identical residues in the query and Hit sequence.
- **Max %Positive.** Shows the percentage of maximum similar but not necessarily identical residues in the query and Hit sequence.

### 12.2.6 Extracting a consensus sequence from a BLAST result

It is possible to batch extract a consensus sequence from a BLAST result. This is described in more detail in section 25.6.

### 12.3 Local BLAST databases

BLAST databases on your local system can be made available for searches via your CLC Genomics Workbench, (section 12.3.1). To make adding databases even easier, you can download pre-formatted BLAST databases from the NCBI from within your CLC Genomics Workbench, (section 12.3.2). You can also easily create your own local blast databases from sequences within your CLC Genomics Workbench, (section 12.3.3).

#### 12.3.1 Make pre-formatted BLAST databases available

To use databases that have been downloaded or created outside the Workbench, you can either:

- Put the database files in one of the locations defined in the BLAST database manager (see section 12.4). All the files that comprise a given BLAST database must be included. This may be as few as three files, but can be more (figure 12.12).
- Add the location where your BLAST databases are stored using the BLAST database manager (see section 12.4) (figure 12.16).

#### 12.3.2 Download NCBI pre-formatted BLAST databases

Many popular pre-formatted databases are available for download from the NCBI. You can download any of the databases available from the list at ftp://ftp.ncbi.nlm.nih.gov/blast/db/ from within your CLC Genomics Workbench.

You must be connected to the internet to use this tool.

To download a database, go to:

**Toolbox | BLAST | Download BLAST Databases**
CHAPTER 12. BLAST SEARCH

Figure 12.12: BLAST databases are made up of several files. The exact number varies and depends on the tool used to build the databases as well as how large the database is. Large databases will be split into the number of volumes and there will be several files per volume. If you have made your BLAST database, or downloaded BLAST database files, outside the Workbench, you will need to ensure that all the files associated with that BLAST database are available in a CLC Blast database location.

A window like the one in figure 12.13 pops up showing you the list of databases available for download.

In this window, you can see the names of the databases, the date they were made available for download on the NCBI site, the size of the files associated with that database, and a brief description of each database. You can also see whether the database has any dependencies. This aspect is described below.

You can also specify which of your database locations you would like to store the files in. Please see the Manage BLAST Databases section for more on this (section 12.4).

There are two very important things to note if you wish to take advantage of this tool.

- Many of the databases listed are very large. Please make sure you have space for them. If you are working on a shared system, we recommend you discuss your plans with your system administrator and fellow users.

- Some of the databases listed are dependent on others. This will be listed in the Dependencies column of the Download BLAST Databases window. This means that while the database you are interested in may seem very small, it may require that you also download a very big database on which it depends.
An example of the second item above is Swissprot. To download a database from the NCBI that would allow you to search just Swissprot entries, you need to download the whole nr database in addition to the entry for Swissprot.

12.3.3 Create local BLAST databases

In the CLC Genomics Workbench you can create a local database that you can use for local BLAST searches. You can specify a location on your computer to save the BLAST database files to. The Workbench will list the BLAST databases found in these locations when you set up a local BLAST search (see section 12.1.2).

DNA, RNA, and protein sequences located in the Navigation Area can be used to create BLAST databases from. Any given BLAST database can only include one molecule type. If you wish to use a pre-formatted BLAST database instead, see section 12.3.1.

To create a BLAST database, go to:

Toolbox | BLAST | Create BLAST Database

This opens the dialog seen in figure 12.14.

Figure 12.14: Add sequences for the BLAST database.

Select sequences or sequence lists you wish to include in your database and click Next.

In the next dialog, shown in figure 12.15, you provide the following information:

- **Name.** The name of the BLAST database. This name will be used when running BLAST searches and also as the base file name for the BLAST database files.

- **Description.** You can add more details to describe the contents of the database.

- **Location.** You can select the location to save the BLAST database files to. You can add or change the locations in this list using the Manage BLAST Databases tool, see section 12.4.

Click Finish to create the BLAST database. Once the process is complete, the new database will be available in the Manage BLAST Databases dialog, see section 12.4, and when running local BLAST (see section 12.1.2).
12.4 Manage BLAST databases

The BLAST databases available as targets for running local BLAST searches (see section 12.1.2) can be managed through the Manage BLAST Databases dialog (see figure 12.16):

At the top of the dialog, there is a list of the **BLAST database locations**. These locations are folders where the Workbench will look for valid BLAST databases. These can either be created from within the Workbench using the **Create BLAST Database tool**, see section 12.3.3, or they can be pre-formatted BLAST databases.

The list of locations can be modified using the **Add Location** and **Remove Location** buttons. Once the Workbench has scanned the locations, it will keep a cache of the databases (in order to improve performance). If you have added new databases that are not listed, you can press **Refresh Locations** to clear the cache and search the database locations again.

**Note:** The BLAST database location and all folders in its path should **not** have any spaces in their names on Linux or Mac systems.

By default a BLAST database location will be added under your home area in a folder called CLCdatabases. This folder is scanned recursively, through all subfolders, to look for valid databases. All other folder locations are scanned only at the top level.

Below the list of locations, all the BLAST databases are listed with the following information:
• **Name.** The name of the BLAST database.

• **Description.** Detailed description of the contents of the database.

• **Date.** The date the database was created.

• **Sequences.** The number of sequences in the database.

• **Type.** The type can be either nucleotide (DNA) or protein.

• **Total size (1000 residues).** The number of residues in the database, either bases or amino acid.

• **Location.** The location of the database.

Below the list of BLAST databases, there is a button to **Remove Database.** This option will delete the database files belonging to the database selected.

### 12.5 Bioinformatics explained: BLAST

BLAST (Basic Local Alignment Search Tool) has become the *de facto* standard in search and alignment tools [Altschul et al., 1990]. The BLAST algorithm is still actively being developed and is one of the most cited papers ever written in this field of biology. Many researchers use BLAST as an initial screening of their sequence data from the laboratory and to get an idea of what they are working on. BLAST is far from being basic as the name indicates; it is a highly advanced algorithm which has become very popular due to availability, speed, and accuracy. In short, a BLAST search identifies homologous sequences by searching one or more databases usually hosted by NCBI ([http://www.ncbi.nlm.nih.gov/](http://www.ncbi.nlm.nih.gov/)), on the query sequence of interest [McGinnis and Madden, 2004].

BLAST is an open source program and anyone can download and change the program code. This has also given rise to a number of BLAST derivatives; WU-BLAST is probably the most commonly used [Altschul and Gish, 1996].

BLAST is highly scalable and comes in a number of different computer platform configurations which makes usage on both small desktop computers and large computer clusters possible.

BLAST can be used for a lot of different purposes. A few of them are mentioned below.

• **Looking for species.** If you are sequencing DNA from unknown species, BLAST may help identify the correct species or homologous species.

• **Looking for domains.** If you BLAST a protein sequence (or a translated nucleotide sequence) BLAST will look for known domains in the query sequence.

• **Looking at phylogeny.** You can use the BLAST web pages to generate a phylogenetic tree of the BLAST result.

• **Mapping DNA to a known chromosome.** If you are sequencing a gene from a known species but have no idea of the chromosome location, BLAST can help you. BLAST will show you the position of the query sequence in relation to the hit sequences.

• **Annotations.** BLAST can also be used to map annotations from one organism to another or look for common genes in two related species.
**Searching for homology**  Most research projects involving sequencing of either DNA or protein have a requirement for obtaining biological information of the newly sequenced and maybe unknown sequence. If the researchers have no prior information of the sequence and biological content, valuable information can often be obtained using BLAST. The BLAST algorithm will search for homologous sequences in predefined and annotated databases of the users choice.

In an easy and fast way the researcher can gain knowledge of gene or protein function and find evolutionary relations between the newly sequenced DNA and well established data.

After the BLAST search the user will receive a report specifying found homologous sequences and their local alignments to the query sequence.

### 12.5.1 How does BLAST work?

BLAST identifies homologous sequences using a heuristic method which initially finds short matches between two sequences; thus, the method does not take the entire sequence space into account. After initial match, BLAST attempts to start local alignments from these initial matches. This also means that BLAST does not guarantee the optimal alignment, thus some sequence hits may be missed. In order to find optimal alignments, the Smith-Waterman algorithm should be used (see below). In the following, the BLAST algorithm is described in more detail.

**Seeding**  When finding a match between a query sequence and a hit sequence, the starting point is the words that the two sequences have in common. A word is simply defined as a number of letters. For blastp the default word size is 3 \( W=3 \). If a query sequence has a QWRTG, the searched words are QWR, WRT, RTG. See figure 12.17 for an illustration of words in a protein sequence.

![Generation of exact BLAST words with a word size of W=3.](image)

During the initial BLAST seeding, the algorithm finds all common words between the query sequence and the hit sequence(s). Only regions with a word hit will be used to build on an alignment.

BLAST will start out by making words for the entire query sequence (see figure 12.17). For each word in the query sequence, a compilation of neighborhood words, which exceed the threshold of \( T \), is also generated.

A neighborhood word is a word obtaining a score of at least \( T \) when comparing, using a selected scoring matrix (see figure 12.18). The default scoring matrix for blastp is BLOSUM62. The compilation of exact words and neighborhood words is then used to match against the database sequences.

After initial finding of words (seeding), the BLAST algorithm will extend the (only 3 residues long) alignment in both directions (see figure 12.19). Each time the alignment is extended, an
Neighborhood BLAST words based on the BLOSUM62 matrix. Only words where the threshold $T$ exceeds 13 are included in the initial seeding.

alignment score is increases/decreased. When the alignment score drops below a predefined threshold, the extension of the alignment stops. This ensures that the alignment is not extended to regions where only very poor alignment between the query and hit sequence is possible. If the obtained alignment receives a score above a certain threshold, it will be included in the final BLAST result.

Query: 325 SLAALLNKCKTPQQQLVQWIKQPLMDEKNIREDRLNLVEA 365
         +LA+L+     TG R++ +W+ P+ D + ER + A
Subject: 290 TLAVALCTVTENGSRMLKRLWLVMPVRDTRVLLERQQTIGA 330

By tweaking the word size $W$ and the neighborhood word threshold $T$, it is possible to limit the search space. E.g. by increasing $T$, the number of neighboring words will drop and thus limit the search space as shown in figure 12.20.

This will increase the speed of BLAST significantly but may result in loss of sensitivity. Increasing the word size $W$ will also increase the speed but again with a loss of sensitivity.

12.5.2 Which BLAST program should I use?

Depending on the nature of the sequence it is possible to use different BLAST programs for the database search. There are five versions of the BLAST program, blastn, blastp, blastx, tblastn, tblastx:

<table>
<thead>
<tr>
<th>Option</th>
<th>Query Type</th>
<th>DB Type</th>
<th>Comparison</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>blastn</td>
<td>Nucleotide</td>
<td>Nucleotide</td>
<td>Nucleotide-Nucleotide</td>
<td></td>
</tr>
<tr>
<td>blastp</td>
<td>Protein</td>
<td>Protein</td>
<td>Protein-Protein</td>
<td></td>
</tr>
<tr>
<td>tblastn</td>
<td>Protein</td>
<td>Nucleotide</td>
<td>Protein-Protein</td>
<td>The database is translated into protein</td>
</tr>
<tr>
<td>blastx</td>
<td>Nucleotide</td>
<td>Protein</td>
<td>Protein-Protein</td>
<td>The queries are translated into protein</td>
</tr>
<tr>
<td>tblastx</td>
<td>Nucleotide</td>
<td>Nucleotide</td>
<td>Protein-Protein</td>
<td>The queries and database are translated into protein</td>
</tr>
</tbody>
</table>

The most commonly used method is to BLAST a nucleotide sequence against a nucleotide database (blastn) or a protein sequence against a protein database (blastp). But often another
Figure 12.20: Each dot represents a word match. Increasing the threshold of T limits the search space significantly.

BLAST program will produce more interesting hits. E.g., if a nucleotide sequence is translated before the search, it is more likely to find better and more accurate hits than just a blastn search. One of the reasons for this is that protein sequences are evolutionarily more conserved than nucleotide sequences. Another good reason for translating the query sequence before the search is that you get protein hits which are likely to be annotated. Thus you can directly see the protein function of the sequenced gene.

12.5.3 Which BLAST options should I change?

The NCBI BLAST web pages and the BLAST command line tool offer a number of different options which can be changed in order to obtain the best possible result. Changing these parameters can have a great impact on the search result. It is not the scope of this document to comment on all of the options available but merely the options which can be changed with a direct impact on the search result.

**The E-value** The expect value (E-value) can be changed in order to limit the number of hits to the most significant ones. The lower the E-value, the better the hit. The E-value is dependent on the length of the query sequence and the size of the database. For example, an alignment obtaining an E-value of 0.05 means that there is a 5 in 100 chance of occurring by chance alone.

E-values are very dependent on the query sequence length and the database size. Short identical sequence may have a high E-value and may be regarded as "false positive" hits. This is often seen if one searches for short primer regions, small domain regions etc. The default threshold
for the E-value on the BLAST web page is 10. Increasing this value will most likely generate more hits. Below are some rules of thumb which can be used as a guide but should be considered with common sense.

- **E-value < 10e-100** Identical sequences. You will get long alignments across the entire query and hit sequence.
- **10e-100 < E-value < 10e-50** Almost identical sequences. A long stretch of the query protein is matched to the database.
- **10e-50 < E-value < 10e-10** Closely related sequences, could be a domain match or similar.
- **10e-10 < E-value < 1** Could be a true homologue but it is a gray area.
- **E-value > 1** Proteins are most likely not related
- **E-value > 10** Hits are most likely junk unless the query sequence is very short.

**Gap costs** For blastp it is possible to specify gap cost for the chosen substitution matrix. There is only a limited number of options for these parameters. The *open* gap cost is the price of introducing gaps in the alignment, and *extension* gap cost is the price of every extension past the initial opening gap. Increasing the gap costs will result in alignments with fewer gaps.

**Filters** It is possible to set different filter options before running the BLAST search. Low-complexity regions have a very simple composition compared to the rest of the sequence and may result in problems during the BLAST search [Wootton and Federhen, 1993]. A low complexity region of a protein can for example look like this ‘fftfflllss’, which in this case is a region as part of a signal peptide. In the output of the BLAST search, low-complexity regions will be marked in lowercase gray characters (default setting). The low complexity region cannot be thought of as a significant match; thus, disabling the low complexity filter is likely to generate more hits to sequences which are not truly related.

**Word size** Change of the word size has a great impact on the seeded sequence space as described above. But one can change the word size to find sequence matches which would otherwise not be found using the default parameters. For instance the word size can be decreased when searching for primers or short nucleotides. For blastn a suitable setting would be to decrease the default word size of 11 to 7, increase the E-value significantly (1000) and turn off the complexity filtering.

For blastp a similar approach can be used. Decrease the word size to 2, increase the E-value and use a more stringent substitution matrix, e.g. a PAM30 matrix.

**Substitution matrix** For protein BLAST searches, a default substitution matrix is provided. If you are looking at distantly related proteins, you should either choose a high-numbered PAM matrix or a low-numbered BLOSUM matrix. The default scoring matrix for blastp is BLOSUM62.
12.5.4 Explanation of the BLAST output

The BLAST output comes in different flavors. On the NCBI web page the default output is html, and the following description will use the html output as example. Ordinary text and xml output for easy computational parsing is also available.

The default layout of the NCBI BLAST result is a graphical representation of the hits found, a table of sequence identifiers of the hits together with scoring information, and alignments of the query sequence and the hits.

![Color key for alignment scores](image)

Figure 12.21: BLAST graphical view. A simple graphical overview of the hits found aligned to the query sequence. The alignments are color coded ranging from black to red as indicated in the color label at the top.

The graphical output (shown in figure 12.21) gives a quick overview of the query sequence and the resulting hit sequences. The hits are colored according to the obtained alignment scores.

The table view (shown in figure 12.22) provides more detailed information on each hit and furthermore acts as a hyperlink to the corresponding sequence in GenBank.

In the alignment view one can manually inspect the individual alignments generated by the BLAST algorithm. This is particularly useful for detailed inspection of the sequence hit found(sbjct) and the corresponding alignment. In the alignment view, all scores are described for each alignment, and the start and stop positions for the query and hit sequence are listed. The strand and orientation for query sequence and hits are also found here.
CHAPTER 12. BLAST SEARCH

Figure 12.22: BLAST table view. A table view with one row per hit, showing the accession number and description field from the sequence file together with BLAST output scores.

![BLAST table view](image)

Figure 12.23: Alignment view of BLAST results. Individual alignments are represented together with BLAST scores and more.

![Alignment view of BLAST results](image)

In most cases, the table view of the results will be easier to interpret than tens of sequence alignments.
12.5.5 I want to BLAST against my own sequence database, is this possible?

It is possible to download the entire BLAST program package and use it on your own computer, institution computer cluster or similar. This is preferred if you want to search in proprietary sequences or sequences unavailable in the public databases stored at NCBI. The downloadable BLAST package can either be installed as a web-based tool or as a command line tool. It is available for a wide range of different operating systems.

The BLAST package can be downloaded free of charge from the following location http://www.ncbi.nlm.nih.gov/BLAST/download.shtml

Pre-formatted databases are available from a dedicated BLAST ftp site ftp://ftp.ncbi.nlm.nih.gov/blast/db/. Moreover, it is possible to download programs/scripts from the same site enabling automatic download of changed BLAST databases. Thus it is possible to schedule a nightly update of changed databases and have the updated BLAST database stored locally or on a shared network drive at all times. Most BLAST databases on the NCBI site are updated on a daily basis to include all recent sequence submissions to GenBank.

A few commercial software packages are available for searching your own data. The advantage of using a commercial program is obvious when BLAST is integrated with the existing tools of these programs. Furthermore, they let you perform BLAST searches and retain annotations on the query sequence (see figure 12.24). It is also much easier to batch download a selection of hit sequences for further inspection.

![Figure 12.24: Snippet of alignment view of BLAST results. Individual alignments are represented directly in a graphical view. The top sequence is the query sequence and is shown with a selection of annotations.](image)

12.5.6 What you cannot get out of BLAST

Don’t expect BLAST to produce the best available alignment. BLAST is a heuristic method which does not guarantee the best results, and therefore you cannot rely on BLAST if you wish to find all the hits in the database.

Instead, use the Smith-Waterman algorithm for obtaining the best possible local alignments [Smith and Waterman, 1981].

BLAST only makes local alignments. This means that a great but short hit in another sequence may not at all be related to the query sequence even though the sequences align well in a small region. It may be a domain or similar.

It is always a good idea to be cautious of the material in the database. For instance, the
sequences may be wrongly annotated; hypothetical proteins are often simple translations of a
found ORF on a sequenced nucleotide sequence and may not represent a true protein.

Don’t expect to see the best result using the default settings. As described above, the settings
should be adjusted according to the what kind of query sequence is used, and what kind of
results you want. It is a good idea to perform the same BLAST search with different settings to
get an idea of how they work. There is not a final answer on how to adjust the settings for your
particular sequence.

12.5.7 Other useful resources

The BLAST web page hosted at NCBI

Download pages for the BLAST programs

Download pages for pre-formatted BLAST databases

O’Reilly book on BLAST
http://www.oreilly.com/catalog/blast/
Proteins are amino acid polymers that are involved in all aspects of cellular function. The structure of a protein is defined by its particular amino acid sequence, with the amino acid sequence being referred to as the primary protein structure. The amino acids fold up in local structural elements; helices and sheets, also called the secondary structure of the protein. These structural elements are then packed into globular folds, known as the tertiary structure or the three dimensional structure.

In order to understand protein function it is often valuable to see the three dimensional structure of the protein. This is possible when the structure of the protein has been resolved and published. Structure files are usually deposited in the Protein Data Bank (PDB) [http://www.rcsb.org/](http://www.rcsb.org/), where the publicly available protein structure files can be searched and downloaded. The vast majority of the protein structures have been determined by X-ray crystallography (88%) while
the rest of the structures predominantly have been obtained by Nuclear Magnetic Resonance techniques.

In addition to protein structures, the PDB entries also contain structural information about molecules that interact with the protein, such as nucleic acids, ligands, cofactors, and water. There are also entries, which contain nucleic acids and no protein structure. The 3D Molecule Viewer in the CLC Genomics Workbench is an integrated viewer of such structure files.

The 3D Molecule Viewer offers a range of tools for inspection and visualization of molecular structures:

- Automatic sorting of molecules into categories: Proteins, Nucleic acids, Ligands, Cofactors, Water molecules
- Hide/unhide individual molecules from the view
- Four different atom-based molecule visualizations
- Backbone visualization for proteins and nucleic acids
- Molecular surface visualization
- Selection of different color schemes for each molecule visualization
- Customized visualization for user selected atoms
- Alignment of protein structures
- Browse amino acids and nucleic acids from sequence editors started from within the 3D Molecule Viewer
- Link a sequence or alignment to a protein structure
- Transfer annotations between the linked sequence and the structure

13.1 Importing molecule structure files

The supported file format for three dimensional protein structures in the 3D Molecule Viewer is the Protein Data Bank (PDB) format, which upon import is converted to a CLC Molecule Project. PDB files can be imported to a Molecule Project in three different ways:

- from the Protein Data Bank
- from your own file system
- using BLAST search against the PDB database

13.1.1 From the Protein Data Bank

Molecule structures can be imported in the workbench from the Protein Data Bank using the "Download" function:

Toolbar | Download (⬇) | Search for PDB structures at NCBI (⬇)
CHAPTER 13. 3D MOLECULE VIEWER

Figure 13.1: Download protein structure from the Protein Data Bank. It is possible to open a structure file directly from the output of the search by clicking the "Download and Open" button or by double clicking directly on the relevant row.

Type the molecule name or accession number into the search field and click on the "Start search" button (as shown in figure 13.1). The search hits will appear in the table below the search field.

Select the molecule structure of interest and click on the button labeled "Download and Open" - or double click on the relevant row - in the table to open the protein structure.

Pressing the "Download and Save" button will save the molecule structure at a user defined destination in the Navigation Area.

The button "Open at NCBI" links directly to the structure summary page at NCBI: clicking this button will open individual NCBI pages describing each of the selected molecule structures.

13.1.2 From your own file system

A PDB file can also be imported from your own file system using the standard import function:

Toolbar | Import | Standard Import

In the Import dialog, select the structure(s) of interest from a data location and tick "Automatic import" (figure 13.2). Specify where to save the imported PDB file and click Finish.

Double clicking on the imported file in the Navigation Area will open the structure as a Molecule Project in the View Area of the CLC Genomics Workbench. Another option is to drag the PDB file from the Navigation Area to the View Area. This will automatically open the protein structure as a Molecule Project.

13.1.3 BLAST search against the PDB database

It is also possible to make a BLAST search against the PDB database, by going to:

Toolbox | BLAST | BLAST at NCBI

After selecting where to run the analysis, specify which input sequences to use for the BLAST search in the "BLAST at NCBI" dialog, within the box named "Select sequences of same type".
 CHAPTER 13. 3D MOLECULE VIEWER

Figure 13.2: A PDB file can be imported using the Standard Import tool.

More than one sequence can be selected at the same time, as long as the sequences are of the same type (figure 13.3).

Figure 13.3: Select the input sequence of interest. In this example a protein sequence for ATPase class I type 8A member 1 and an ATPase ortholog from S. pombe have been selected.

Click Next and choose program and database (figure 13.4). When a protein sequence has been used as input, select "Program: blastp: Protein sequence and database" and "Database: Protein Data Bank proteins (pdb)".

It is also possible to use mRNA and genomic sequences as input. In such cases the program "blastx: Translated DNA sequence and protein database" should be used.

Figure 13.4: Select database and program.

Please refer to section 12.1.1 for further description of the individual parameters in the wizard steps.

When you click on the button labeled Finish, a BLAST output is generated that shows local
sequence alignments between your input sequence and a list of matching proteins with known structures available.

Note! The BLAST at NCBI search can take up to several minutes, especially when mRNA and genomic sequences are used as input.

Switch to the "BLAST Table" editor view to select the desired entry (figure 13.5). If you have performed a multi BLAST, to get access to the "BLAST Table" view, you must first double click on each row to open the entries individually.

In this view four different options are available:

- **Download and Open** The sequence that has been selected in the table is downloaded and opened in the View Area.
- **Download and Save** The sequence that has been selected in the table is downloaded and saved in the Navigation Area.
- **Open at NCBI** The protein sequence that has been selected in the table is opened at NCBI.
- **Open Structure** Opens the selected structure in a Molecule Project in the View Area.

![Figure 13.5: Top: The output from "BLAST at NCBI". Bottom: The "BLAST table". One of the protein sequences has been selected. This activates the four buttons under the table. Note that the table and the BLAST Graphics are linked, this means that when a sequence is selected in the table, the same sequence will be highlighted in the BLAST Graphics view.](image)

### 13.1.4 Import issues

When opening an imported molecule file for the first time, a notification is briefly shown in the lower left corner of the Molecule Project editor, with information of the number of issues encountered during import of the file. The issues are categorized and listed in a table view in the Issues view. The Issues list can be opened by selecting **Show | Issues** from the menu appearing when right-clicking in an empty space in the 3D view (figure 13.6).
Alternatively, the issues can be accessed from the lower left corner of the view, where buttons are shown for each available view. If you hold down the Ctrl key (Cmd on Mac) while clicking on the Issues icon, the list will be shown in a split view together with the 3D view. The issues list is linked with the molecules in the 3D view, such that selecting an entry in the list will select the implicated atoms in the view, and zoom to put them into the center of the 3D view.

Figure 13.6: At the bottom of the Molecule Project it is possible to switch to the "Show Issues" view by clicking on the "table-with-exclamation-mark" icon.

13.2 Viewing molecular structures in 3D

An example of a 3D structure that has been opened as a Molecule Project is shown in figure 13.7.

Figure 13.7: 3D view of a calcium ATPase. All molecules in the PDB file are shown in the Molecule Project. The Project Tree in the right side of the window lists the involved molecules.

Moving and rotating The molecules can be rotated by holding down the left mouse button while moving the mouse. The right mouse button can be used to move the view. Zooming can be done with the scroll-wheel or by holding down both left and right buttons while moving the mouse up and down.

All molecules in the Molecule Project are listed in categories in the Project Tree. The individual molecules or whole categories can be hidden from the view by un-checking the boxes next to them. It is possible to bring a particular molecule or a category of molecules into focus by selecting the molecule or category of interest in the Project Tree view and double-click on the molecule or
category of interest. Another option is to use the zoom-to-fit button (•••) at the bottom of the Project Tree view.

**Troubleshooting 3D graphics errors**  The 3D viewer uses OpenGL graphics hardware acceleration in order to provide the best possible experience. If you experience any graphics problems with the 3D view, please make sure that the drivers for your graphics card are up-to-date.

If the problems persist after upgrading the graphics card drivers, it is possible to change to a rendering mode, which is compatible with a wider range of graphic cards. To change the graphics mode go to Edit in the menu bar, select “Preferences”, Click on “View”, scroll down to the bottom and find “Molecule Project 3D Editor” and uncheck the box “Use modern OpenGL rendering”.

Finally, it should be noted that certain types of visualization are more demanding than others. In particular, using multiple molecular surfaces may result in slower drawing, and even result in the graphics card running out of available memory. Consider creating a single combined surface (by using a selection) instead of creating surfaces for each single object. For molecules with a large number of atoms, changing to wireframe rendering and hiding hydrogen atoms can also greatly improve drawing speed.

### 13.2.1 Updating old structure files

A completely redesign of the 3D Molecule Viewer was released in August 2013. It is therefore necessary to update older structure files. To update existing structure files, double click on the name in the Navigation Area. This will bring up the dialog shown in figure 13.8, which via the "Download from PDB..." button gives access to downloading the specific structure in PDB format.

![Image](image_url)

**Figure 13.8:** Old structure files are not supported by the new 3D Molecule Viewer and must be updated.
13.3 Customizing the visualization

The molecular visualization of all molecules in the Molecule Project can be customized using different visualization styles. The styles can be applied to one molecule at a time, or to a whole category (or a mixture), by selecting the name of either the molecule or the category. Holding down the Ctrl (Cmd on Mac) or shift key while clicking the entry names in the Project Tree will select multiple molecules/categories.

The six leftmost quick-style buttons below the Project Tree view give access to the molecule visualization styles, while context menus on the buttons (accessible via right-click or left-click-hold) give access to the color schemes available for the visualization styles. Visualization styles and color schemes are also available from context menus directly on the selected entries in the Project Tree. Other quick-style buttons are available for displaying hydrogen bonds between Project Tree entries, for displaying labels in the 3D view and for creating custom atom groups. They are all described in detail below.

Note! Whenever you wish to change the visualization styles by right-clicking the entries in the Project Tree, please be aware that you must first click on the entry of interest, and ensure it is highlighted in blue, before right-clicking.

13.3.1 Visualization styles and colors

Wireframe, Stick, Ball and stick, Space-filling/CPK

Four different ways of visualizing molecules by showing all atoms are provided: Wireframe, Stick, Ball and stick, and Space-filling/CPK.

The visualizations are mutually exclusive meaning that only one style can be applied at a time for each selected molecule or atom group.

Six color schemes are available and can be accessed via right-clicking on the quick-style buttons:

- Color by Element. Classic CPK coloring based on atom type (e.g. oxygen red, carbon gray, hydrogen white, nitrogen blue, sulfur yellow).

- Color by Temperature. For PDB files, this is based on the b-factors. For structure models created with tools in a CLC workbench, this is based on an estimate of the local model quality. The color scale goes from blue (0) over white (50) to red (100). The b-factors as well as the local model quality estimate are measures of uncertainty or disorder in the atom position; the higher the number, the higher the uncertainty.

- Color Carbons by Entry. Each entry (molecule or atom group) is assigned its own specific color. Only carbon atoms are colored by the specific color, other atoms are colored by element.

- Color by Entry. Each entry (molecule or atom group) is assigned its own specific color.

- Custom Color. The user selects a molecule color from a palette.

- Custom Carbon Color. The user selects a molecule color from a palette. Only carbon atoms are colored by the specific color, other atoms are colored by element.
CHAPTER 13. 3D MOLECULE VIEWER

Backbone

For the molecules in the Proteins and Nucleic Acids categories, the backbone structure can be visualized in a schematic rendering, highlighting the secondary structure elements for proteins and matching base pairs for nucleic acids. The backbone visualization can be combined with any of the atom-level visualizations.

Five color schemes are available for backbone structures:

- Color by Residue Position. Rainbow color scale going from blue over green to yellow and red, following the residue number.
- Color by Type. For proteins, beta sheets are blue, helices red and loops/coil gray. For nucleic acids backbone ribbons are white while the individual nucleotides are indicated in green (T/U), red (A), yellow (G), and blue (C).
- Color by Backbone Temperature. For PDB files, this is based on the b-factors for the Cα atoms (the central carbon atom in each amino acid). For structure models created with tools in the workbench, this is based on an estimate of the local model quality. The color scale goes from blue (0) over white (50) to red (100). The b-factors as well as the local model quality estimate are measures of uncertainty or disorder in the atom position; the higher the number, the higher the uncertainty.
- Color by Entry. Each chain/molecule is assigned its own specific color.
- Custom Color. The user selects a molecule color from a palette.

Surfaces

Molecular surfaces can be visualized.

Five color schemes are available for surfaces:

- Color by Charge. Charged amino acids close to the surface will show as red (negative) or blue (positive) areas on the surface, with a color gradient that depends on the distance of the charged atom to the surface.
- Color by Element. Smoothed out coloring based on the classic CPK coloring of the heteroatoms close to the surface.
- Color by Temperature. Smoothed out coloring based on the temperature values assigned to atoms close to the surface (See the "Wireframe, Stick, Ball and stick, Space-filling/CPK" section above).
- Color by Entry. Each surface is assigned its own specific color.
- Custom Color. The user selects a surface color from a palette.
A surface spanning multiple molecules can be visualized by creating a custom atom group that includes all atoms from the molecules (see section 13.3.1). It is possible to adjust the opacity of a surface by adjusting the transparency slider at the bottom of the menu.

![Figure 13.9: Transparent surfaces](image)

Notice that visual artifacts may appear when rotating a transparent surface. These artifacts disappear as soon as the mouse is released.

**Labels**

Labels can be added to the molecules in the view by selecting an entry in the Project Tree and clicking the label button at the bottom of the Project Tree view. The color of the labels can be adjusted from the context menu by right clicking on the selected entry (which must be highlighted in blue first) or on the label button in the bottom of the Project Tree view (see figure 13.10).

![Figure 13.10: The color of the labels can be adjusted in two different ways. Either directly using the label button by right clicking the button, or by right clicking on the molecule or category of interest in the Project Tree.](image)

- For proteins and nucleic acids, each residue is labeled with the PDB name and number.
- For ligands, each atom is labeled with the atom name as given in the input.
- For cofactors and water, one label is added with the name of the molecule.
- For atom groups including protein atoms, each protein residue is labeled with the PDB name and number.
- For atom groups not including protein atoms, each atom is labeled with the atom name as given in the input.

Labels can be removed again by clicking on the label button.

**Hydrogen bonds**

The Show Hydrogen Bond visualization style may be applied to molecules and atom group entries in the project tree. If this style is enabled for a project tree entry, hydrogen bonds will be shown to all other currently visible objects. The hydrogen bonds are updated dynamically: if a molecule is toggled off, the hydrogen bonds to it will not be shown.

It is possible to customize the color of the hydrogen bonds using the context menu.

![Figure 13.11: The hydrogen bond visualization setting, with custom bond color.](image)

**Create atom group**

Often it is convenient to use a unique visualization style or color to highlight a particular set of atoms, or to visualize only a subset of atoms from a molecule. This can be achieved by creating an atom group. Atom groups can be created based on atoms selected in the 3D view or entries selected in the Project Tree. When an atom group has been created, it appears as an entry in the Project Tree in the category "Atom groups". The atoms can then be hidden or shown, and the visualization changed, just as for the molecule entries in the Project Tree.

Note that an atom group entry can be renamed. Select the atom group in the Project Tree and invoke the right-click context menu. Here, the Rename option is found.

**Create atom group based on atoms selected in 3D view**

When atoms are selected in the 3D view, brown spheres indicate which atoms are included in the selection. The selection will appear as the entry "Current" in the Selections category in the Project Tree.

Once a selection has been made, press the "Create Atom Group" button and a context menu will show different options for creating a new atom group based on the selection:
CHAPTER 13. 3D MOLECULE VIEWER

Figure 13.12: An atom group that has been highlighted by adding a unique visualization style.

- **Selected Atoms.** Creates an atom group containing exactly the selected atoms (those indicated by brown spheres). If an entire molecule or residue is selected, this option is not displayed.

- **Selected Residue(s)/Molecules.** Creates an atom group that includes all atoms in the selected residues (for entries in the protein and nucleic acid categories) and molecules (for the other categories).

- **Nearby Atoms.** Creates an atom group that contains residues (for the protein and nucleic acid categories) and molecules (for the other categories) within 5 Å of the selected atoms. Only atoms from currently visible Project Tree entries are considered.

- **Hydrogen Bonded Atoms.** Creates an atom group that contains residues (for the protein and nucleic acid categories) and molecules (for the other categories) that have hydrogen bonds to the selected atoms. Only atoms from currently visible Project Tree entries are considered.

There are several ways to select atoms in the 3D view:

- **Double click to select.** Click on an atom to select it. When you double click on an atom that belongs to a residue in a protein or in a nucleic acid chain, the entire residue will be selected. For small molecules, the entire molecule will be selected.

- **Adding atoms to a selection.** Holding down Ctrl while picking atoms, will pile up the atoms in the selection. All atoms in a molecule or category from the Project Tree, can be added to the "Current" selection by choosing "Add to Current Selection" in the context menu. Similarly, entire molecules can be removed from the current selection via the context menu.

- **Spherical selection.** Hold down the shift-key, click on an atom and drag the mouse away from the atom. Then a sphere centered on the atom will appear, and all atoms inside the sphere, visualized with one of the all-atom representations will be selected. The status bar (lower right corner) will show the radius of the sphere.

- **Show Sequence.** Another option is to select protein or nucleic acid entries in the Project Tree, and click the "Show Sequence" button found below the Project Tree (section 13.4.1).
A split-view will appear with a sequence editor for each of the sequence data types (Protein, DNA, RNA) (figure 13.13). If you then select residues in the sequence view, the backbone atoms of the selected residues will show up as the "Current" selection in the 3D view and the Project Tree view. Notice that the link between the 3D view and the sequence editor is lost if either window is closed, or if the sequence is modified.

- **Align to Existing Sequence.** If a single protein chain is selected in the Project Tree, the "Align to Existing Sequence" button can be clicked (section 13.4.2). This links the protein sequence with a sequence or sequence alignment found in the Navigation Area. A split-view appears with a sequence alignment where the sequence of the selected protein chain is linked to the 3D structure, and atoms can be selected in the 3D view, just as for the "Show Sequence" option.

![Figure 13.13: The protein sequence in the split view is linked with the protein structure. This means that when a part of the protein sequence is selected, the same region in the protein structure will be selected.]

**Create atom group based on entries selected in the Project Tree**

Select one or more entries in the Project Tree, and press the "Create Atom Group" button, then a context menu will show different options for creating a new atom group based on the selected entries:

- **Nearby Atoms.** Creates an atom group that contains residues (for the protein and nucleic acid categories) and molecules (for the other categories) within 5 Å of the selected entries. Only atoms from currently visible Project Tree entries are considered.

- **Hydrogen Bonded Atoms.** Creates an atom group that contains residues (for the protein and nucleic acid categories) and molecules (for the other categories) that have hydrogen bonds to the selected entries. Only atoms from currently visible Project Tree entries are considered.

If a Binding Site Setup is present in the Project Tree (A Binding Site Setup could only be created using the now discontinued CLC Drug Discovery Workbench), and entries from the Ligands or
Docking results categories are selected, two extra options are available under the header **Create Atom Group (Binding Site)**. For these options, atom groups are created considering all molecules included in the Binding Site Setup, and thus not taking into account which Project Tree entries are currently visible.

**Zoom to fit**

The “Zoom to fit” button can be used to automatically move a region of interest into the center of the screen. This can be done by selecting a molecule or category of interest in the Project Tree view followed by a click on the "Zoom to fit" button at the bottom of the Project Tree view (figure 13.14). Double-clicking an entry in the Project Tree will have the same effect.

Figure 13.14: The "Fit to screen" button can be used to bring a particular molecule or category of molecules in focus.

### 13.3.2 Project settings

A number of general settings can be adjusted from the **Side Panel**. Personal settings as well as molecule visualizations can be saved by clicking in the lower right corner of the **Side Panel** (/fixtures). This is described in detail in section 4.6.

**Project Tree Tools**

Just below the Project Tree, the following tools are available

- **Show Sequence** Select molecules which have sequences associated (Protein, DNA, RNA) in the Project Tree, and click this button. Then, a split-view will appear with a sequence editor for each of the sequence data types (Protein, DNA, RNA). This is described in section 13.4.1.

- **Align to Existing Sequence** Select a protein chain in the Project Tree, and click this button. Then protein sequences and sequence alignments found in the Navigation Area, can be
linked with the protein structure. This is described in section 13.4.2.

- **Transfer Annotations** Select a protein chain in the Project Tree, that has been linked with a sequence using either the "Show Sequence" or "Align to Existing Sequence" options. Then it is possible to transfer annotations between the structure and the linked sequence. This is described in section 13.4.3.

- **Align Protein Structure** This will invoke the dialog for aligning protein structures based on global alignment of whole chains or local alignment of e.g. binding sites defined by atom groups. This is described in section 13.5.

**Property viewer**

The Property viewer, found in the Side Panel, lists detailed information about the atoms that the mouse hovers over. For all atoms the following information is listed:

- **Molecule** The name of the molecule the atom is part of.
- **Residue** For proteins and nucleic acids, the name and number of the residue the atom belongs to is listed, and the chain name is displayed in parentheses.
- **Name** The particular atom name, if given in input, with the element type (Carbon, Nitrogen, Oxygen...) displayed in parentheses.
- **Hybridization** The atom hybridization assigned to the atom.
- **Charge** The atomic charge as given in the input file. If charges are not given in the input file, some charged chemical groups are automatically recognized and a charge assigned.

For atoms in molecules imported from a PDB file, extra information is given:

- **Temperature** Here is listed the b-factor assigned to the atom in the PDB file. The b-factor is a measure of uncertainty or disorder in the atom position; the higher the number, the higher the disorder.
- **Occupancy** For each atom in a PDB file, the occupancy is given. It is typically 1, but if atoms are modeled in the PDB file, with no foundation in the raw data, the occupancy is 0. If a residue or molecule has been resolved in multiple positions, the occupancy is between 0 and 1.

For atoms in protein models created by tools in the workbench, the following extra information is given:

- **Temperature** For structure models, the temperature value is an estimate of local structure uncertainty. The three aspects contributing to the assigned atom temperature is also listed, and described in section 27.5.5. The temperature value is a measure of uncertainty or disorder in the atom position; the higher the number, the higher the disorder.
- **Occupancy** For modeled structures and atoms, the occupancy is set to zero.
If an atom is selected, the Property view will be frozen with the details of the selected atom shown. If then a second atom is selected (by holding down Ctrl while clicking), the distance between the two selected atoms is shown. If a third atom is selected, the angle for the second atom selected is shown. If a fourth atom is selected, the dihedral angle measured as the angle between the planes formed by the three first and three last selected atoms is given.

Figure 13.15: Selecting two, three, or four atoms will display the distance, angle, or dihedral angle, respectively.

If a molecule is selected in the Project Tree, the Property view shows information about this molecule. Two measures are always shown:

- **Atoms** Number of atoms in the molecule.
- **Weight** The weight of the molecule in Daltons.

**Visualization settings**

Under "Visualization" five options exist:

- **Hydrogens** Hydrogen atoms can be shown (Show all hydrogens), hidden (Hide all hydrogens) or partially shown (Show only polar hydrogens).

- **Fog** "Fog" is added to give a sense of depth in the view. The strength of the fog can be adjusted or it can be disabled.

- **Clipping plane** This option makes it possible to add an imaginary plane at a specified distance along the camera’s line of sight. Only objects behind this plane will be drawn. It is possible to clip only surfaces, or to clip surfaces together with proteins and nucleic acids. Small molecules, like ligands and water molecules, are never clipped.

- **3D projection** The view is opened up towards the viewer, with a "Perspective" 3D projection. The field of view of the perspective can be adjusted, or the perspective can be disabled by selecting an orthographic 3D projection.

- **Coloring** The background color can be selected from a color palette by clicking on the colored box.

**Snapshots of the molecule visualization** To save the current view as a picture, right-click in the View Area and select "File" and "Export Graphics". Another way to save an image is by pressing
the "Graphics" button in the Workbench toolbar (\[\text{button}\]). Next, select the location where you wish to save the image, select file format (PNG, JPEG, or TIFF), and provide a name, if you wish to use another name than the default name.

You can also save the current view directly on data with a custom name, so that it can later be applied (see section 4.6).

### 13.4 Tools for linking sequence and structure

The CLC Genomics Workbench has functionality that allows you to link a protein sequence to a protein structure. Selections made on the sequence will show up on the structure. This allows you to explore a protein sequence in a 3D structure context. Furthermore, sequence annotations can be transferred to annotations on the structure and annotations on the structure can be transferred to annotations on the sequence (see section 13.4.3).

#### 13.4.1 Show sequence associated with molecule

From the Side Panel, sequences associated with the molecules in the Molecule Project can be opened as separate objects by selecting protein or nucleic acid entries in the Project Tree and clicking the button labeled "Show Sequence" (figure 13.16). This will generate a Sequence or Sequence List for each selected sequence type (protein, DNA, RNA). The sequences can be used to select atoms in the Molecular Project as described in section 13.3.1. The sequences can also be used as input for sequence analysis tools or be saved as independent objects. You can later re-link to the sequence using "Align to Existing Sequence" (see section 13.4.2).

![Figure 13.16: Protein chain sequences and DNA sequences are shown in separate views.](image)

#### 13.4.2 Link sequence or sequence alignment to structure

The "Align to Existing Sequence" button can be used to map and link existing sequences or sequence alignments to a protein structure chain in a Molecule Project (3D view). It can also be used to reconnect a protein structure chain to a sequence or sequence alignment previously created by Show Sequence (section 13.4.1) or Align to Existing Sequence.

Select a single protein chain in the project tree (see figure 13.17). Pressing "Align to Existing
Sequence" then opens a Navigation Area browser, where it is possible to select one or more Sequence, Sequence Lists, or Alignments, to link with the selected protein chain.

Figure 13.17: Select a single protein chain in the Project Tree and invoke "Align to Existing Sequence".

If the sequences or alignments already contain a sequence identical to the protein chain selected in the Molecule Project (i.e. same name and amino acid sequence), this sequence is linked to the protein structure. If no identical sequence is present, a sequence is extracted from the protein structure (as for Show Sequence - section 13.4.1), and a sequence alignment is created between this sequence and the sequences or alignments selected from the Navigation Area. The new sequence alignment is created (see section 20.1) with the following settings:

- Gap open cost: 10.0
- Gap Extension cost: 1.0
- End gap cost: free
- Existing alignments are not redone

When the link is established, selections on the linked sequence in the sequence editor will create atom selections in the 3D view, and it is possible to transfer annotations between the linked sequence and the 3D protein chain (see section 13.4.3). Notice, that the link will be broken if either the sequence or the 3D protein chain is modified.

Two tips if the link is to a sequence in an alignment:

1. Read about how to change the layout of sequence alignments in section 20.2
2. It is only annotations present on the sequence linked to the 3D view that can be transferred to atom groups on the structure. To transfer sequence annotations from other sequences in the alignment, first copy the annotations to the sequence in the alignment that is linked to the structure (see figure 13.20 and section 20.3).

13.4.3 Transfer annotations between sequence and structure

The Transfer Annotations dialog makes it possible to create new atom groups (annotations on structure) based on protein sequence annotations and vice versa.
You can read more about sequence annotations in section 11.3 and more about atom groups in section 13.3.1.

Before it is possible to transfer annotations, a link between a protein sequence editor and a Molecule Project (a 3D view) must be established. This is done either by opening a sequence associated with a protein chain in the 3D view using the 'Show Sequence' button (see section 13.4.1) or by mapping to an existing sequence or sequence alignment using the 'Align to Existing Sequence' button (see section 13.4.2).

Invoke the Transfer Annotations dialog by selecting a linked protein chain in the Project Tree and press 'Transfer Annotations' (see figure 13.18).

The dialog contains two tables (see figure 13.19). The left table shows all atom groups in the Molecule Project, with at least one atom on the selected protein chain. The right table shows all annotations present on the linked sequence. While the Transfer Annotations dialog is open, it is not possible to make changes to neither the sequence nor the Molecule Project, however, changes to the visualization styles are allowed.

How to undo annotation transfers

In order to undo operations made using the Transfer Annotations dialog, the dialog must first be closed. To undo atom groups added to the structure, activate the 3D view by clicking in it and press Undo in the Toolbar. To undo annotations added to the sequence, activate the sequence view by clicking in it and press Undo in the Toolbar.

Transfer sequence annotations from aligned sequences

It is only annotations present on the sequence linked to the 3D view that can be transferred to atom groups on the structure. If you wish to transfer annotations that are found on other sequences in a linked sequence alignment, you need first to copy the sequence annotations to the actual sequence linked to the 3D view (the sequence with the same name as the protein structure). This is done by invoking the context menu on the sequence annotation you wish to
Figure 13.19: The Transfer Annotations dialog allow you to select annotations listed in the two tables, and copy them from structure to sequence or vice versa.

copy (see figure 13.20 and section 20.3).

Figure 13.20: Copy annotations from sequences in the alignment to the sequence linked to the 3D view.

### 13.5 Protein structure alignment

The Align Protein Structure tool allows you to compare a protein or binding pocket in a Molecule Project with proteins from other Molecule Projects. The tool is invoked using the Align Protein Structure action from the Molecule Project Side Panel. This action will open an interactive dialog box (figure 13.21). By default, when the dialog box is closed with an "OK", a new Molecule Project will be opened containing all the input protein structures laid on top of one another. All molecules coming from the same input Molecule Project will have the same color in the initial visualization.
13.5.1 The Align Protein Structure dialog box

The dialog box contains three fields:

- **Select reference (protein chain or atom group)** This drop-down menu shows all the protein chains and residue-containing atom groups in the current Molecule Project. If an atom group is selected, the structural alignment will be optimized in that area. The 'All chains from Molecule Project' option will create a global alignment to all protein chains in the project, fitting e.g. a dimer to a dimer.

- **Molecule Projects with molecules to be aligned** One or more Molecule Projects containing protein chains may be selected.

- **Output options** The default output is a single Molecule Project containing all the input projects rotated onto the coordinate system of the reference. Several alignment statistics, including the RMSD, TM-score, and sequence identity, are added to the History of the output Molecule Project. Additionally, a sequence alignments of the aligned structures may be output, with the sequences linked to the 3D structure view.

13.5.2 Example: alignment of calmodulin

Calmodulin is a calcium binding protein. It is composed of two similar domains, each of which binds two calcium atoms. The protein is especially flexible, which can make structure alignment challenging. Here we will compare the calcium binding loops of two calmodulin crystal structures -- PDB codes 1A29 and 4G28.

**Initial global alignment** The 1A29 project is opened and the Align Protein Structure dialog is filled out as in figure 13.21. Selecting "All chains from 1A29" tells the aligner to make the best possible global alignment, favoring no particular region. The output of the alignment is shown in figure 13.22. The blue chain is from 1A29, the brown chain is the corresponding calmodulin
chain from 4G28 (a calmodulin-binding chain from the 4G28 file has been hidden from the view). Because calmodulin is so flexible, it is not possible to align both of its domains (enclosed in black boxes) at the same time. A good global alignment would require the brown protein to be translated in one direction to match the N-terminal domain, and in the other direction to match the C-terminal domain (see black arrows).

![Figure 13.22: Global alignment of two calmodulin structures (blue and brown). The two domains of calmodulin (shown within black boxes) can undergo large changes in relative orientation. In this case, the different orientation of the domains in the blue and brown structures makes a good global alignment impossible: the movement required to align the brown structure onto the blue is shown by arrows – as the arrows point in opposite directions, improving the alignment of one domain comes at the cost of worsening the alignment of the other.](image)

Focusing the alignment on the N-terminal domain To align only the N-terminal domain, we return to the 1A29 project and select the Show Sequence action from beneath the Project Tree. We highlight the first 62 residues, then convert them into an atom group by right-clicking on the "Current" selection in the Project Tree and choosing "Create Group from Selection" (figure 13.23). Using the new atom group as the reference in the alignment dialog leads to the alignment shown in figure 13.24. In addition to the original input proteins, the output now includes two Atom Groups, which contain the atoms on which the alignment was focused. The History of the output Molecule Project shows that the alignment has 0.9 Å RMSD over the 62 residues.

Aligning a binding site Two bound calcium atoms, one from each calmodulin structure, are shown in the black box of figure 13.24. We now wish to make an alignment that is as good as possible about these atoms so as to compare the binding modes. We return to the 1A29 project, right-click the calcium atom from the cofactors list in the Project Tree and select "Create Nearby Atoms Group". Using the new atom group as the reference in the alignment dialog leads to the alignment shown in figure 13.25.

13.5.3 The Align Protein Structure algorithm

Any approach to structure alignment must make a trade-off between alignment length and alignment accuracy. For example, is it better to align 200 amino acids at an RMSD of 3.0 Å or 150 amino acids at an RMSD of 2.5 Å? The Align Protein Structure algorithm determines
Figure 13.23: Creation of an atom group containing the N-terminal domain of calmodulin.

Figure 13.24: Alignment of the same two calmodulin proteins as in figure 13.22, but this time with a focus on the N-terminal domain. The blue and brown structures are now well-superimposed in the N-terminal region. The black box encloses two calcium atoms that are bound to the structures.

The answer to this question by taking the alignment with the higher TM-score. For an alignment focused on a protein of length \( L \), this is:

\[
\text{TM-score} = \frac{1}{L} \sum_{i} \frac{1}{1 + \frac{d_i}{d(L)^2}}
\]

where \( i \) runs over the aligned pairs of residues, \( d_i \) is the distance between the \( i^{th} \) such pair, and \( d(L) \) is a normalization term that approximates the average distance between two randomly chosen points in a globular protein of length \( L \) [Zhang and Skolnick, 2004]. A perfect alignment has a TM-score of 1.0, and two proteins with a TM-score >0.5 are often said to show structural homology [Xu and Zhang, 2010].

The Align Protein Structure Algorithm attempts to find the structure alignment with the highest TM-score. This problem reduces to finding a sequence alignment that pairs residues in a way that results in a high TM-score. Several sequence alignments are tried including an alignment with the BLOSUM62 matrix, an alignment of secondary structure elements, and iterative refinements of these alignments.
Figure 13.25: Alignment of the same two calmodulin domains as in figure 13.22, but this time with a focus on the calcium atom within the black box of figure 13.24. The calcium atoms are less than 1 Å apart – compatible with thermal motion encoded in the atoms’ temperature factors.

The Align Protein Structure Algorithm is also capable of aligning entire protein complexes. To do this, it must determine the correct pairing of each chain in one complex with a chain in the other. This set of chain pairings is determined by the following procedure:

1. Make structure alignments between every chain in one complex and every chain in the other. Discard pairs of chains that have a TM-score of < 0.4

2. Find all pairs of structure alignments that are consistent with each other i.e. are achieved by approximately the same rotation

3. Use a heuristic to combine consistent pairs of structure alignments into a single alignment

The heuristic used in the last step is similar to that of MM-align [Mukherjee and Zhang, 2009], whereas the first two steps lead to both a considerable speed up and increased accuracy. The alignment of two 30S ribosome subunits, each with 20 protein chains, can be achieved in less than a minute (PDB codes 2QBD and 1FJG).

CLC Genomics Workbench offers different kinds of sequence analyses that apply to both protein and DNA.

The analyses are described in this chapter.

14.1 Extract Annotations

The Extract annotations tool makes it very easy to extract parts of a sequence (or several sequences) based on its annotations. In just a few steps, it becomes possible to:
• extract all tRNA genes from a genome.
• automatically add flanking regions to the annotated sequences.
• search for specific words in all available annotations.
• extract nucleotide sequences of differentially expressed genes or transcripts when using RNA-seq statistical comparisons as input.

The output is a sequence list that contains sequences carrying the annotation specified (including the flanking regions, if this option was selected).

To extract annotations from a sequence, go to:

Toolbox  |  Utility Tools  |  Extract Annotations

This opens the dialog shown in figure 32.9 where you can select one or more annotated sequences, or annotation tracks, or variant tracks, or statistical comparisons. Click Next.

Figure 14.1: Select one or more annotated sequences, annotations, variant tracks or (in this figure) statistical comparisons.

If you selected tracks as input, the next step will ask for a reference sequence track to use for extracting the annotations, or which annotations to use if an annotated sequence was selected as input (figure 32.10).

• Search terms. All annotations and attached information for each annotation will be searched for the entered term. It can be used to make general searches for search terms such as "Gene" or "Exon", or it can be used to make more specific searches. For example, if you have a gene annotation called "MLH1" and another called "MLH3", you can extract both annotations by entering "MLH" in the search term field. If you wish to enter more specific search terms, separate them with commas: "MLH1, Human" will find annotations including both "MLH1" and "Human".

• Annotation types If only certain types of annotations should be extracted, this can be specified here.

The sequence of interest can be extracted with flanking sequences:

• Flanking upstream residues. The output will include this number of extra residues at the 5’ end of the annotation.

• Flanking downstream residues. The output will include this number of extra residues at the 3’ end of the annotation.
The sequences that are created can be named after the annotation name, type etc:

- **Include annotation name.** This will use the name of the annotation in the name of the extracted sequence.

- **Include annotation type.** This corresponds to the type chosen above and will put this information in the name of the resulting sequences. This is useful information if you have chosen to extract "All" types of annotations.

- **Include annotation region.** The region covered by the annotation on the original sequence (i.e. not including flanking regions) will be included in the name.

- **Include sequence/track name.** If you have selected more than one sequence as input, this option enables you to discern the origin of the resulting sequences in the list by putting the name of the original sequence into the name of the resulting sequences.

Click **Finish** to start the tool.

### 14.2 Extract sequences

This tool allows the extraction of sequences from other types of data in the Workbench, such as sequence lists or alignments. The data types you can extract sequences from are:

- Alignments
- BLAST result
- BLAST overview tables
- sequence lists
• Contigs and read mappings
• Read mapping tables
• Read mapping tracks
• RNA-Seq mapping results

**Note!** When the Extract Sequences tool is run via the Workbench toolbox on an entire file of one of the above types, all sequences are extracted from the data used as input. If only a subset of the sequences is desired, for example, the reads from just a small area of a mapping, or the sequences for only a few blast results, then a data set containing just this subsection or subset should be created and the Extract Sequences tool should be run on that.

For extracting a subset of a mapping, please see section 18.7.6 that describes the function "Extract from Selection" that also can be selected from the right click menu (see figure 14.3).

For extracting a subset of a sequence list, you can highlight the sequences of interest in the table view of the sequence list, right click on the selection and launch the Extract Sequences tool.

The Extract Sequences tool can be launched via the Toolbox menu, by going to:

**Toolbox | Classical Sequence Analysis | General Sequence Analysis | Extract Sequences**

Alternatively, on all the data types listed above except sequence lists, the option to run this tool appears by right clicking in the relevant area; a row in a table or in the read area of mapping data. An example is shown in figure 14.3.

Please note that for mappings, only the read sequences are extracted. Reference and consensus sequences are not extracted using this tool. Similarly, when extracting sequences from BLAST results, the sequence hits are extracted, not the original query sequence or a consensus sequence.

"Note also, that paired reads will be extracted in accordance with the read group settings, which is specified during the original import of the reads. If the orientation has since been changed (e.g. using the Element Info tab for the sequence list) the read group information will be modified and reads will be extracted as specified by the modified read group. The default read group orientation is forward-reverse."

The dialog allows you to select the **Destination**. Here you can choose whether the extracted sequences should be extracted as single sequences or placed in a new sequence list. For most data types, it will make most sense to choose to extract the sequences into a sequence list. The exception to this is when working with a sequence list, where choosing to extract to a sequence list would create a copy of the same sequence list. In this case, the other option would generally be chosen. This would then result in the generation of individual sequence objects for each sequence in the sequence list.

Below these options, in the dialog, you can see the number of sequences that will be extracted.

### 14.3 Shuffle sequence

In some cases, it is beneficial to shuffle a sequence. This is an option in the **Toolbox** menu under **General Sequence Analyses**. It is normally used for statistical analyses, e.g. when comparing an...
alignment score with the distribution of scores of shuffled sequences.

Shuffling a sequence removes all annotations that relate to the residues. To launch the tool, go to:

Toolbox | Classical Sequence Analysis | General Sequence Analysis | Shuffle Sequence

Choose a sequence for shuffling. If a sequence was selected before choosing the Toolbox action, this sequence is now listed in the Selected Elements window of the dialog. Use the arrows to add or remove sequences or sequence lists, from the selected elements.

Click Next to determine how the shuffling should be performed.

In this step, shown in figure 14.5:

For nucleotides, the following parameters can be set:

- **Mononucleotide shuffling.** Shuffle method generating a sequence of the exact same mononucleotide frequency

- **Dinucleotide shuffling.** Shuffle method generating a sequence of the exact same dinucleotide frequency

- **Mononucleotide sampling from zero order Markov chain.** Resampling method generating
a sequence of the same expected mononucleotide frequency.

- **Dinucleotide sampling from first order Markov chain.** Resampling method generating a sequence of the same expected dinucleotide frequency.

For proteins, the following parameters can be set:

- **Single amino acid shuffling.** Shuffle method generating a sequence of the exact same amino acid frequency.

- **Single amino acid sampling from zero order Markov chain.** Resampling method generating a sequence of the same expected single amino acid frequency.

- **Dipeptide shuffling.** Shuffle method generating a sequence of the exact same dipeptide frequency.

- **Dipeptide sampling from first order Markov chain.** Resampling method generating a sequence of the same expected dipeptide frequency.

For further details of these algorithms, see [Clote et al., 2005]. In addition to the shuffle method, you can specify the number of randomized sequences to output.

Click **Finish** to start the tool.

This will open a new view in the **View Area** displaying the shuffled sequence. The new sequence is not saved automatically. To save the sequence, drag it into the **Navigation Area** or press ctrl + S (⌘ + S on Mac) to activate a save dialog.

### 14.4 Dot plots

Dot plots provide a powerful visual comparison of two sequences. Dot plots can also be used to compare regions of similarity within a sequence.

A dot plot is a simple, yet intuitive way of comparing two sequences, either DNA or protein, and is probably the oldest way of comparing two sequences [Maizel and Lenk, 1981]. A dot plot is a 2 dimensional matrix where each axis of the plot represents one sequence. By sliding a fixed size window over the sequences and making a sequence match by a dot in the matrix, a diagonal line will emerge if two identical (or very homologous) sequences are plotted against each other. Dot
plots can also be used to visually inspect sequences for direct or inverted repeats or regions with low sequence complexity. Various smoothing algorithms can be applied to the dot plot calculation to avoid noisy background of the plot. Moreover, various substitution matrices can be applied in order to take the evolutionary distance of the two sequences into account.

### 14.4.1 Create dot plots

To create a dot plot, go to:

Toolbox | Classical Sequence Analysis | General Sequence Analysis | Create Dot Plot

In the dialog that opens, select a sequence and click Next to adjust dot plot parameters (figure 14.6).

![Figure 14.6: Setting the dot plot parameters.](image)

There are two parameters for calculating the dot plot:

- **Distance correction (only valid for protein sequences)** In order to treat evolutionary transitions of amino acids, a distance correction measure can be used when calculating the dot plot. These distance correction matrices (substitution matrices) take into account the likeliness of one amino acid changing to another.

- **Window size** A residue by residue comparison (window size = 1) would undoubtedly result in a very noisy background due to a lot of similarities between the two sequences of interest. For DNA sequences the background noise will be even more dominant as a match between only four nucleotide is very likely to happen. Moreover, a residue by residue comparison (window size = 1) can be very time consuming and computationally demanding. Increasing the window size will make the dot plot more 'smooth'.

**Note!** Calculating dot plots takes up a considerable amount of memory in the computer. Therefore, you will see a warning message if the sum of the number of nucleotides/amino acids in the sequences is higher than 8000. If you insist on calculating a dot plot with more residues the Workbench may shut down, but still allowing you to save your work first. However, this depends on your computer’s memory configuration.

Click **Finish** to start the tool.
14.4.2 View dot plots

A view of a dot plot can be seen in figure 14.7. You can select **Zoom in** in the Toolbar and click the dot plot to zoom in to see the details of particular areas.

![Dot plot](image)

Figure 14.7: A view is opened showing the dot plot.

The **Side Panel** to the right let you specify the dot plot preferences. The gradient color box can be adjusted to get the appropriate result by dragging the small pointers at the top of the box. Moving the slider from the right to the left lowers the thresholds which can be directly seen in the dot plot, where more diagonal lines will emerge. You can also choose another color gradient by clicking on the gradient box and choose from the list.

Adjusting the sliders above the gradient box is also practical, when producing an output for printing. (Too much background color might not be desirable). By crossing one slider over the other (the two sliders change side) the colors are inverted, allowing for a white background. (If you choose a color gradient, which includes white). See figure 14.7.

14.4.3 Bioinformatics explained: Dot plots

Dot plots are two-dimensional plots where the x-axis and y-axis each represents a sequence and the plot itself shows a comparison of these two sequences by a calculated score for each position of the sequence. If a window of fixed size on one sequence (one axis) match to the other sequence a dot is drawn at the plot. Dot plots are one of the oldest methods for comparing two sequences [Maizel and Lenk, 1981].

The scores that are drawn on the plot are affected by several issues.

- **Scoring matrix for distance correction.**
  Scoring matrices (BLOSUM and PAM) contain substitution scores for every combination of two amino acids. Thus, these matrices can only be used for dot plots of protein sequences.

- **Window size**
  The single residue comparison (bit by bit comparison(window size = 1)) in dot plots will undoubtedly result in a noisy background of the plot. You can imagine that there are many
successes in the comparison if you only have four possible residues like in nucleotide sequences. Therefore you can set a window size which is smoothing the dot plot. Instead of comparing single residues it compares subsequences of length set as window size. The score is now calculated with respect to aligning the subsequences.

- Threshold
  The dot plot shows the calculated scores with colored threshold. Hence you can better recognize the most important similarities.

Examples and interpretations of dot plots

Contrary to simple sequence alignments dot plots can be a very useful tool for spotting various evolutionary events which may have happened to the sequences of interest.

Below is shown some examples of dot plots where sequence insertions, low complexity regions, inverted repeats etc. can be identified visually.

Similar sequences

The most simple example of a dot plot is obtained by plotting two homologous sequences of interest. If very similar or identical sequences are plotted against each other a diagonal line will occur.

The dot plot in figure 14.9 shows two related sequences of the Influenza A virus nucleoproteins infecting ducks and chickens. Accession numbers from the two sequences are: DQ232610 and DQ023146. Both sequences can be retrieved directly from http://www.ncbi.nlm.nih.gov/gquery/gquery.fcgi.

Repeated regions

Sequence repeats can also be identified using dot plots. A repeat region will typically show up as lines parallel to the diagonal line.

If the dot plot shows more than one diagonal in the same region of a sequence, the regions
CHAPTER 14. GENERAL SEQUENCE ANALYSES

Figure 14.9: Dot plot of DQ232610 vs. DQ023146 (Influenza A virus nucleoproteins) showing and overall similarity

Figure 14.10: Direct and inverted repeats shown on an amino acid sequence generated for demonstration purposes.

depending to the other sequence are repeated. In figure 14.11 you can see a sequence with repeats.

Frame shifts
Frame shifts in a nucleotide sequence can occur due to insertions, deletions or mutations. Such frame shifts can be visualized in a dot plot as seen in figure 14.12. In this figure, three frame shifts for the sequence on the y-axis are found.

1. Deletion of nucleotides
2. Insertion of nucleotides
3. Mutation (out of frame)
Sequence inversions

In dot plots you can see an inversion of sequence as contrary diagonal to the diagonal showing similarity. In figure 14.13 you can see a dot plot (window length is 3) with an inversion.

Low-complexity regions

Low-complexity regions in sequences can be found as regions around the diagonal all obtaining a high score. Low complexity regions are calculated from the redundancy of amino acids within a limited region [Wootton and Federhen, 1993]. These are most often seen as short regions of only a few different amino acids. In the middle of figure 14.14 is a square shows the low-complexity region of this sequence.

14.4.4 Bioinformatics explained: Scoring matrices

Biological sequences have evolved throughout time and evolution has shown that not all changes to a biological sequence is equally likely to happen. Certain amino acid substitutions (change of one amino acid to another) happen often, whereas other substitutions are very rare. For instance, tryptophan (W) which is a relatively rare amino acid, will only — on very rare occasions — mutate into a leucine (L).

Based on evolution of proteins it became apparent that these changes or substitutions of amino
acids can be modeled by a scoring matrix also referred to as a substitution matrix. See an example of a scoring matrix in table 14.1. This matrix lists the substitution scores of every single amino acid. A score for an aligned amino acid pair is found at the intersection of the corresponding column and row. For example, the substitution score from an arginine (R) to a lysine (K) is 2. The diagonal shows scores for amino acids which have not changed. Most substitutions changes have a negative score. Only rounded numbers are found in this matrix.

The two most used matrices are the BLOSUM [Henikoff and Henikoff, 1992] and PAM [Dayhoff and Schwartz, 1978].

**Different scoring matrices**

**PAM**
The first PAM matrix (Point Accepted Mutation) was published in 1978 by Dayhoff et al. The PAM matrix was build through a global alignment of related sequences all having sequence similarity above 85% [Dayhoff and Schwartz, 1978]. A PAM matrix shows the probability that any given amino acid will mutate into another in a given time interval. As an example, PAM1 gives that one amino acid out of a 100 will mutate in a given time interval. In the other end of the scale, a PAM256 matrix, gives the probability of 256 mutations in a 100 amino acids (see figure 14.15).

There are some limitation to the PAM matrices which makes the BLOSUM matrices somewhat more attractive. The dataset on which the initial PAM matrices were build is very old by now, and
the PAM matrices assume that all amino acids mutate at the same rate - this is not a correct assumption.

**BLOSUM**

In 1992, 14 years after the PAM matrices were published, the BLOSUM matrices (BLOcks SUBstitution Matrix) were developed and published [Henikoff and Henikoff, 1992].

Henikoff et al. wanted to model more divergent proteins, thus they used locally aligned sequences where none of the aligned sequences share less than 62% identity. This resulted in a scoring matrix called BLOSUM62. In contrast to the PAM matrices the BLOSUM matrices are calculated from alignments without gaps emerging from the BLOCKS database [http://blocks.fhcrc.org/](http://blocks.fhcrc.org/).

Sean Eddy recently wrote a paper reviewing the BLOSUM62 substitution matrix and how to calculate the scores [Eddy, 2004].

**Use of scoring matrices**

Deciding which scoring matrix you should use in order to obtain the best alignment results is a difficult task. If you have no prior knowledge on the sequence the BLOSUM62 is probably the best choice. This matrix has become the *de facto* standard for scoring matrices and is also used as the default matrix in BLAST searches. The selection of a "wrong" scoring matrix will most probable strongly influence on the outcome of the analysis. In general a few rules apply to the selection of scoring matrices.
For closely related sequences choose BLOSUM matrices created for highly similar alignments, like BLOSUM80. You can also select low PAM matrices such as PAM1.

For distant related sequences, select low BLOSUM matrices (for example BLOSUM45) or high PAM matrices such as PAM250.

The BLOSUM matrices with low numbers correspond to PAM matrices with high numbers. (See figure 14.15) for correlations between the PAM and BLOSUM matrices. To summarize, if you want to find distant related proteins to a sequence of interest using BLAST, you could benefit of using BLOSUM45 or similar matrices.

Figure 14.15: Relationship between scoring matrices. The BLOSUM62 has become a de facto standard scoring matrix for a wide range of alignment programs. It is the default matrix in BLAST.
Table 14.1: The BLOSUM62 matrix. A tabular view of the BLOSUM62 matrix containing all possible substitution scores [Henikoff and Henikoff, 1992].

14.5 Local complexity plot

In CLC Genomics Workbench it is possible to calculate local complexity for both DNA and protein sequences. The local complexity is a measure of the diversity in the composition of amino acids within a given range (window) of the sequence. The K2 algorithm is used for calculating local complexity [Wootton and Federhen, 1993]. To conduct a complexity calculation do the following:

Toolbox | Classical Sequence Analysis ( ) | General Sequence Analysis ( ) | Create Complexity Plot ( )

This opens a dialog. In Step 1 you can use the arrows to change, remove and add DNA and protein sequences in the Selected Elements window.

When the relevant sequences are selected, clicking Next takes you to Step 2. This step allows you to adjust the window size from which the complexity plot is calculated. Default is set to 11 amino acids and the number should always be odd. The higher the number, the less volatile the graph.

Figure 14.16 shows an example of a local complexity plot.

Click Finish to start the tool. The values of the complexity plot approaches 1.0 as the distribution of amino acids become more complex.
CHAPTER 14. GENERAL SEQUENCE ANALYSES

14.6 Sequence statistics

CLC Genomics Workbench can produce an output with many relevant statistics for protein sequences. Some of the statistics are also relevant to produce for DNA sequences. Therefore, this section deals with both types of statistics. The required steps for producing the statistics are the same.

To create a statistic for the sequence, do the following:

1. Toolbox | Classical Sequence Analysis | General Sequence Analysis | Create Sequence Statistics

Select one or more sequence(s) or/and one or more sequence list(s). Note! You cannot create statistics for DNA and protein sequences at the same time, they must be run separately.

Next (figure 14.17), the dialog offers to adjust the following parameters:

- **Individual statistics layout.** If more sequences were selected in Step 1, this function generates separate statistics report for each sequence.

- **Comparative statistics layout.** If more sequences were selected in Step 1, this function generates statistics with comparisons between the sequences.

You can also choose to include Background distribution of amino acids. If this box is ticked, an extra column with amino acid distribution of the chosen species, is included in the table output. (The distributions are calculated from UniProt www.uniprot.org version 6.0, dated September 13 2005.)

Click Finish to start the tool. An example of protein sequence statistics is shown in figure 14.18.
Nucleotide sequence statistics are generated using the same dialog as used for protein sequence statistics. However, the output of Nucleotide sequence statistics is less extensive than that of the protein sequence statistics.

**Note!** The headings of the tables change depending on whether you calculate individual or comparative sequence statistics.

The output of protein sequence statistics includes:

- **Sequence Information:**
  - Sequence type
  - Length
  - Organism
  - Name
  - Description
  - Modification Date
  - Weight. This is calculated like this: \( \sum_{\text{units in sequence}} \text{weight(unit)} - \text{links} \times \text{weight(H2O)} \) where \( \text{links} \) is the sequence length minus one and \( \text{units} \) are amino acids. The atomic composition is defined the same way.
  - Isoelectric point
  - Aliphatic index

- Amino acid counts, frequencies
- Annotation counts
The output of nucleotide sequence statistics include:

- **General statistics:**
  - Sequence type
  - Length
  - Organism
  - Name
  - Description
  - Modification Date
  - Weight (calculated as single-stranded and double-stranded DNA)

- Annotation table

- Nucleotide distribution table

If nucleotide sequences are used as input, and these are annotated with CDS, a section on Codon statistics for Coding Regions is included.

A short description of the different areas of the statistical output is given in section 14.6.1.

### 14.6.1 Bioinformatics explained: Protein statistics

Every protein holds specific and individual features which are unique to that particular protein. Features such as isoelectric point or amino acid composition can reveal important information of a novel protein. Many of the features described below are calculated in a simple way.

- **Molecular weight** The molecular weight is the mass of a protein or molecule. The molecular weight is simply calculated as the sum of the atomic mass of all the atoms in the molecule. The weight of a protein is usually represented in Daltons (Da).

  A calculation of the molecular weight of a protein does not usually include additional posttranslational modifications. For native and unknown proteins it tends to be difficult to assess whether posttranslational modifications such as glycosylations are present on the protein, making a calculation based solely on the amino acid sequence inaccurate. The molecular weight can be determined very accurately by mass-spectrometry in a laboratory.

- **Isoelectric point** The isoelectric point (pI) of a protein is the pH where the proteins has no net charge. The pI is calculated from the pKa values for 20 different amino acids. At a pH below the pI, the protein carries a positive charge, whereas if the pH is above pI the proteins carry a negative charge. In other words, pI is high for basic proteins and low for acidic proteins. This information can be used in the laboratory when running electrophoretic gels. Here the proteins can be separated, based on their isoelectric point.

- **Aliphatic index** The aliphatic index of a protein is a measure of the relative volume occupied by aliphatic side chain of the following amino acids: alanine, valine, leucine and isoleucine. An increase in the aliphatic index increases the thermostability of globular proteins. The index is calculated by the following formula.

</table>

#### Aliphatic index

\[
\text{Aliphatic index} = X(\text{Ala}) + a \times X(\text{Val}) + b \times X(\text{Leu}) + b \times (X)\text{Ile}
\]

\(X(\text{Ala}), X(\text{Val}), X(\text{Ile})\) and \(X(\text{Leu})\) are the amino acid compositional fractions. The constants \(a\) and \(b\) are the relative volume of valine \((a=2.9)\) and leucine/isoleucine \((b=3.9)\) side chains compared to the side chain of alanine [Ikai, 1980].

- **Estimated half-life** The half life of a protein is the time it takes for the protein pool of that particular protein to be reduced to the half. The half life of proteins is highly dependent on the presence of the N-terminal amino acid, thus overall protein stability [Bachmair et al., 1986, Gonda et al., 1989, Tobias et al., 1991]. The importance of the N-terminal residues is generally known as the ‘N-end rule’. The N-end rule and consequently the N-terminal amino acid, simply determines the half-life of proteins. The estimated half-life of proteins have been investigated in mammals, yeast and *E. coli* (see Table 14.2). If leucine is found N-terminally in mammalian proteins the estimated half-life is 5.5 hours.

- **Extinction coefficient** This measure indicates how much light is absorbed by a protein at a particular wavelength. The extinction coefficient is measured by UV spectrophotometry, but can also be calculated. The amino acid composition is important when calculating the extinction coefficient. The extinction coefficient is calculated from the absorbance of cysteine, tyrosine and tryptophan using the following equation:

\[
\text{Ext(Protein)} = \text{count(Cystine)} \times \text{Ext(Cystine)} + \text{count(Tyr)} \times \text{Ext(Tyr)} + \text{count(Trp)} \times \text{Ext(Trp)}
\]

where Ext is the extinction coefficient of amino acid in question. At 280nm the extinction coefficients are: Cys=120, Tyr=1280 and Trp=5690. This equation is only valid under the following conditions:
The extinction coefficient values of the three important amino acids at different wavelengths are found in [Gill and von Hippel, 1989]. Knowing the extinction coefficient, the absorbance (optical density) can be calculated using the following formula:

\[
\text{Absorbance}(\text{Protein}) = \frac{\text{Ext}(\text{Protein})}{\text{Molecular weight}}
\]

Two values are reported. The first value is computed assuming that all cysteine residues appear as half cystines, meaning they form di-sulfide bridges to other cysteines. The second number assumes that no di-sulfide bonds are formed.

- **Atomic composition** Amino acids are indeed very simple compounds. All 20 amino acids consist of combinations of only five different atoms. The atoms which can be found in these simple structures are: Carbon, Nitrogen, Hydrogen, Sulfur, Oxygen. The atomic composition of a protein can for example be used to calculate the precise molecular weight of the entire protein.

- **Total number of negatively charged residues (Asp + Glu)** At neutral pH, the fraction of negatively charged residues provides information about the location of the protein. Intracellular proteins tend to have a higher fraction of negatively charged residues than extracellular proteins.

- **Total number of positively charged residues (Arg + Lys)** At neutral pH, nuclear proteins have a high relative percentage of positively charged amino acids. Nuclear proteins often bind to the negatively charged DNA, which may regulate gene expression or help to fold the DNA. Nuclear proteins often have a low percentage of aromatic residues [Andrade et al., 1998].

- **Amino acid distribution** Amino acids are the basic components of proteins. The amino acid distribution in a protein is simply the percentage of the different amino acids represented in a particular protein of interest. Amino acid composition is generally conserved through family-classes in different organisms which can be useful when studying a particular protein or enzymes across species borders. Another interesting observation is that amino acid composition variate slightly between proteins from different subcellular localizations. This fact has been used in several computational methods, used for prediction of subcellular localization.

- **Annotation table** This table provides an overview of all the different annotations associated with the sequence and their incidence.

- **Dipeptide distribution** This measure is simply a count, or frequency, of all the observed adjacent pairs of amino acids (dipeptides) found in the protein. It is only possible to report neighboring amino acids. Knowledge on dipeptide composition have previously been used for prediction of subcellular localization.

### 14.7 Join sequences

CLC Genomics Workbench can join several nucleotide or protein sequences into one sequence. This feature can for example be used to construct "supergenes" for phylogenetic inference.
by joining several disjoint genes into one. Note, that when sequences are joined, all their
annotations are carried over to the new spliced sequence.

Two (or more) sequences can be joined by:

Toolbox | General Sequence Analyses | Join sequences

This opens the dialog shown in figure 14.19.

![Figure 14.19: Selecting two sequences to be joined.]

If you have selected some sequences before choosing the Toolbox action, they are now listed in
the Selected Elements window of the dialog. Use the arrows to add or remove sequences from
the selected elements. Click Next opens the dialog shown in figure 14.20.

![Figure 14.20: Setting the order in which sequences are joined.]

In step 2 you can change the order in which the sequences will be joined. Select a sequence and
use the arrows to move the selected sequence up or down.

Click Finish to start the tool.

The result is shown in figure 14.21.

![Figure 14.21: The result of joining sequences is a new sequence containing the annotations of the
joined sequences (they each had a HBB annotation).]

14.8 Pattern discovery

With CLC Genomics Workbench you can perform pattern discovery on both DNA and protein
sequences. Advanced hidden Markov models can help to identify unknown sequence patterns
across single or even multiple sequences.
In order to search for unknown patterns:

Choose one or more sequence(s) or sequence list(s). You can perform the analysis on several DNA or several protein sequences at a time. If the analysis is performed on several sequences at a time the method will search for patterns which is common between all the sequences. Annotations will be added to all the sequences and a view is opened for each sequence.

Click **Next** to adjust parameters (see figure 14.22).

![Pattern Discovery](image)

Figure 14.22: Setting parameters for the pattern discovery. See text for details.

In order to search unknown sequences with an already existing model:

Select to use an already existing model which is seen in figure 14.22. Models are represented with the following icon in the **Navigation Area**.

### 14.8.1 Pattern discovery search parameters

Various parameters can be set prior to the pattern discovery. The parameters are listed below and a screenshot of the parameter settings can be seen in figure 14.22.

- **Create and search with new model.** This will create a new HMM model based on the selected sequences. The found model will be opened after the run and presented in a table view. It can be saved and used later if desired.

- **Use existing model.** It is possible to use already created models to search for the same pattern in new sequences.

- **Minimum pattern length.** Here, the minimum length of patterns to search for, can be specified.

- **Maximum pattern length.** Here, the maximum length of patterns to search for, can be specified.

- **Noise (%).** Specify noise-level of the model. This parameter has influence on the level of degeneracy of patterns in the sequence(s). The noise parameter can be 1, 2, 5 or 10 percent.
• **Number of different kinds of patterns to predict.** Number of iterations the algorithm goes through. After the first iteration, we force predicted pattern-positions in the first run to be member of the background: In that way, the algorithm finds new patterns in the second iteration. Patterns marked 'Pattern1' have the highest confidence. The maximal iterations to go through is 3.

• **Include background distribution.** For protein sequences it is possible to include information on the background distribution of amino acids from a range of organisms.

Click **Finish** to start the tool. This will open a view showing the patterns found as annotations on the original sequence (see figure 14.23). If you have selected several sequences, a corresponding number of views will be opened.

![Figure 14.23: Sequence view displaying two discovered patterns.](image)

### 14.8.2 Pattern search output

If the analysis is performed on several sequences at a time the method will search for patterns in the sequences and open a new view for each of the sequences, in which a pattern was discovered. Each novel pattern will be represented as an annotation of the type **Region**. More information on each found pattern is available through the tool-tip, including detailed information on the position of the pattern and quality scores.

It is also possible to get a tabular view of all found patterns in one combined table. Then each found pattern will be represented with various information on obtained scores, quality of the pattern and position in the sequence.

A table view of emission values of the actual used HMM model is presented in a table view. This model can be saved and used to search for a similar pattern in new or unknown sequences.

### 14.9 Motif Search

**CLC Genomics Workbench** offers advanced and versatile options to search for known motifs represented either by a simple sequence or a more advanced regular expression. These advanced search capabilities are available for use in both DNA and protein sequences.

There are two ways to access this functionality:

- When viewing sequences, it is possible to have motifs calculated and shown on the sequence in a similar way as restriction sites (see section 19.1.1). This approach is called **Dynamic motifs** and is an easy way to spot known sequence motifs when working with sequences for cloning etc.

- A more refined and systematic search for motifs can be performed through the **Toolbox**. This will generate a table and optionally add annotations to the sequences.

The two approaches are described below.
14.9.1 Dynamic motifs

In the Side Panel of sequence views, there is a group called Motifs (see figure 14.24).

The Workbench will look for the listed motifs in the sequence that is open and by clicking the check box next to the motif it will be shown in the view as illustrated in figure 14.25.

This case shows the CMV promoter primer sequence which is one of the pre-defined motifs in CLC Genomics Workbench. The motif is per default shown as a faded arrow with no text. The direction of the arrow indicates the strand of the motif.

Placing the mouse cursor on the arrow will display additional information about the motif as illustrated in figure 14.26.

To add Labels to the motif, select the Flag or Stacked option. They will put the name of the motif as a flag above the sequence. The stacked option will stack the labels when there is more than one motif so that all labels are shown.

Below the labels option there are two options for controlling the way the sequence should be searched for motifs:

- Include reverse motifs. This will also find motifs on the negative strand (only available for nucleotide sequences)
• **Exclude matches in N-regions for simple motifs.** The motif search handles ambiguous characters in the way that two residues are different if they do not have any residues in common. For example: For nucleotides, N matches any character and R matches A,G. For proteins, X matches any character and Z matches E,Q. Genome sequence often have large regions with unknown sequence. These regions are very often padded with N’s. Ticking this checkbox will not display hits found in N-regions and if a one residue in a motif matches to an N, it will be treated as a mismatch.

The list of motifs shown in figure 14.24 is a pre-defined list that is included with the workbench, but you can define your own set of motifs to use instead. In order to do this, you can either launch the Create Motif List tool from the Navigation Area or using the Add Motif button in the side panel (see section 14.10). Once your list of custom motif(s) is saved, you can click the Manage Motifs button in the side panel which will bring up the dialog shown in figure 14.27.

![Figure 14.27: Managing the motifs to be shown.](image)

At the top, select a motif list by clicking the Browse button. When the motif list is selected, its motifs are listed in the panel in the left-hand side of the dialog. The right-hand side panel contains the motifs that will be listed in the Side Panel when you click Finish.

### 14.9.2 Motif search from the Toolbox

The dynamic motifs described in section 14.9.1 provide a quick way of routinely scanning a sequence for commonly used motifs, but in some cases a more systematic approach is needed. The motif search in the Toolbox provides an option to search for motifs with a user-specified similarity to the target sequence, and furthermore the motifs found can be displayed in an overview table. This is particularly useful when searching for motifs on many sequences.

To start the Toolbox motif search, go to:

**Toolbox | Classical Sequence Analysis | General Sequence Analysis | Motif Search**

A dialog window will be launched. Use the arrows to add or remove sequences or sequence lists between the Navigation Area and the selected elements.

You can perform the analysis on several DNA or several protein sequences at a time. In this case, the method will search for patterns in the sequences and create an overview table of the motifs found in all sequences.

Click **Next** to adjust parameters (see figure 14.28).

The options for the motif search are:
CHAPTER 14. GENERAL SEQUENCE ANALYSES

Figure 14.28: Setting parameters for the motif search.

- **Motif types.** Choose what kind of motif to be used:
  - Simple motif. Choosing this option means that you enter a simple motif, e.g. ATGATGNNATG.
  - Java regular expression. See section 14.9.3.
  - Prosite regular expression. For proteins, you can enter different protein patterns from the PROSITE database (protein patterns using regular expressions and describing specific amino acid sequences). The PROSITE database contains a great number of patterns and have been used to identify related proteins (see http://www.expasy.org/cgi-bin/prosite-list.pl).
  - Use motif list. Clicking the small button \( \text{\textdollar} \) will allow you to select a saved motif list (see section 14.10).

- **Motif.** If you choose to search with a simple motif, you should enter a literal string as your motif. Ambiguous amino acids and nucleotides are allowed. Example; ATGATGNNATG. If your motif type is Java regular expression, you should enter a regular expression according to the syntax rules described in section 14.9.3. Press Shift + F1 key for options. For proteins, you can search with a Prosite regular expression and you should enter a protein pattern from the PROSITE database.

- **Accuracy.** If you search with a simple motif, you can adjust the accuracy of the motif to the match on the sequence. If you type in a simple motif and let the accuracy be 80%, the motif search algorithm runs through the input sequence and finds all subsequences of the same length as the simple motif such that the fraction of identity between the subsequence and the simple motif is at least 80%. A motif match is added to the sequence as an annotation with the exact fraction of identity between the subsequence and the simple motif. If you use a list of motifs, the accuracy applies only to the simple motifs in the list.

- **Search for reverse motif.** This enables searching on the negative strand on nucleotide sequences.

- **Exclude unknown regions.** Genome sequence often have large regions with unknown sequence. These regions are very often padded with N’s. Ticking this checkbox will not display hits found in N-regions. Motif search handles ambiguous characters in the way that
two residues are different if they do not have any residues in common. For example: For nucleotides, \( N \) matches any character and \( R \) matches \( A,G \). For proteins, \( X \) matches any character and \( Z \) matches \( E,Q \).

Click **Next** to adjust how to handle the results and then click **Finish**. There are two types of results that can be produced:

- **Add annotations.** This will add an annotation to the sequence when a motif is found (an example is shown in figure 14.29).

- **Create table.** This will create an overview table of all the motifs found for all the input sequences.

![Figure 14.29: Sequence view displaying the pattern found. The search string was 'tataaa'.](image)

### 14.9.3 Java regular expressions

A regular expression is a string that describes or matches a set of strings, according to certain syntax rules. They are usually used to give a concise description of a set, without having to list all elements. The simplest form of a regular expression is a literal string. The syntax used for the regular expressions is the Java regular expression syntax (see [http://java.sun.com/docs/books/tutorial/essential/regex/index.html](http://java.sun.com/docs/books/tutorial/essential/regex/index.html)). Below is listed some of the most important syntax rules which are also shown in the help pop-up when you press Shift + F1:

- \([A-Z]\) will match the characters \( A \) through \( Z \) (Range). You can also put single characters between the brackets: The expression \([AG]\) matches the characters \( A \), \( G \) or \( T \).

- \([A-D]\{M-P\}\) will match the characters \( A \) through \( D \) and \( M \) through \( P \) (Union). You can also put single characters between the brackets: The expression \([AG]\{M-P\}\) matches the characters \( A \), \( G \) and \( M \) through \( P \).

- \([A-M]\&\&\{H-P\}\) will match the characters between \( A \) and \( M \) lying between \( H \) and \( P \) (Intersection). You can also put single characters between the brackets. The expression \([A-M]\&\&\{HGTDA\}\) matches the characters \( A \) through \( M \) which is \( H \), \( G \), \( T \), \( D \) or \( A \).

- \([^\{A-M\}\] will match any character except those between \( A \) and \( M \) (Excluding). You can also put single characters between the brackets: The expression \([^\{AG\}\] matches any character except \( A \) and \( G \).

- \([A-Z]\&\&[^\{M-P\}\]) will match any character \( A \) through \( Z \) except those between \( M \) and \( P \) (Subtraction). You can also put single characters between the brackets: The expression \([A-P]\&\&[^\{CG\}\]) matches any character between \( A \) and \( P \) except \( C \) and \( G \).
The symbol . matches any character.

$X[n]$ will match a repetition of an element indicated by following that element with a numerical value or a numerical range between the curly brackets. For example, $ACG[2]$ matches the string ACGG and $(ACG)[2]$ matches ACGACG.

$X[n,m]$ will match a certain number of repetitions of an element indicated by following that element with two numerical values between the curly brackets. The first number is a lower limit on the number of repetitions and the second number is an upper limit on the number of repetitions. For example, $ACT[1,3]$ matches ACT, ACTT and ACTTT.

$X[n,]$ represents a repetition of an element at least $n$ times. For example, $(AC)[2,]$ matches all strings ACAC, ACACAC, ACACACAC, ...

The symbol ¯ restricts the search to the beginning of your sequence. For example, if you search through a sequence with the regular expression ¯AC, the algorithm will find a match if AC occurs in the beginning of the sequence.

The symbol $ restricts the search to the end of your sequence. For example, if you search through a sequence with the regular expression GT$, the algorithm will find a match if GT occurs in the end of the sequence.

**Examples**

The expression $[ACG]¯ACG(2)$ matches all strings of length 4, where the first character is A, C or G and the second is any character except A, C and the third and fourth character is G. The expression $G.[¯A]$ matches all strings of length 3 in the end of your sequence, where the first character is C, the second any character and the third any character except A.

### 14.10 Create motif list

*CLC Genomics Workbench* offers advanced and versatile options to create lists of sequence patterns or known motifs, represented either by a literal string or a regular expression.

A motif list can be created using:

**Toolbox | Classical Sequence Analysis | General Sequence Analysis | Create Motif List**

Click on the Add button at the bottom of the view. This will open a dialog shown in figure 14.30.

![Figure 14.30: Entering a new motif in the list.](image-url)
In this dialog, you can enter the following information:

- **Name.** The name of the motif. In the result of a motif search, this name will appear as the name of the annotation and in the result table.

- **Motif.** The actual motif. See section 14.9.2 for more information about the syntax of motifs.

- **Description.** You can enter a description of the motif. In the result of a motif search, the description will appear in the result table and will be added as a note to the annotation on the sequence (visible in the Annotation table or by placing the mouse cursor on the annotation).

- **Type.** You can enter three different types of motifs: Simple motifs, java regular expressions or PROSITE regular expression. Read more in section 14.9.2.

The motif list can contain a mix of different types of motifs. This is practical because some motifs can be described with the simple syntax, whereas others need the more advanced regular expression syntax.

Instead of manually adding motifs, you can Import From Fasta File. This will show a dialog where you can select a fasta file on your computer and use this to create motifs. This will automatically take the name, description and sequence information from the fasta file, and put it into the motif list. The motif type will be "simple". Note that reformatting Prosite file into FASTA format for import will fail, as only simple motifs can be imported this way and regular expressions are not supported.

Besides adding new motifs, you can also edit and delete existing motifs in the list. To edit a motif, either double-click the motif in the list, or select and click the Edit button at the bottom of the view.

To delete a motif, select it and press the Delete key on the keyboard. Alternatively, click Delete in the Tool bar.

Save the motif list in the Navigation Area, and you will be able to use for Motif Search (see section 14.9).

  15.6.1 Open reading frame parameters .............................. 351

CLC Genomics Workbench offers different kinds of sequence analyses, which only apply to DNA and RNA.

15.1 Convert DNA to RNA

CLC Genomics Workbench lets you convert a DNA sequence into RNA, substituting the T residues (Thymine) for U residues (Uracil):

Toolbox | Classical Sequence Analysis ( ) | Nucleotide Analysis ( ) | Convert DNA to RNA ( )

This opens the dialog displayed in figure 15.1:

Figure 15.1: Translating DNA to RNA.

If a sequence was selected before choosing the Toolbox action, this sequence is now listed in
the *Selected Elements* window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements.

Click **Finish** to start the tool.

**Note!** You can select multiple DNA sequences and sequence lists at a time. If the sequence list contains RNA sequences as well, they will not be converted.

## 15.2 Convert RNA to DNA

*CLC Genomics Workbench* lets you convert an RNA sequence into DNA, substituting the U residues (Uracil) for T residues (Thymine):

1. Choose where to run
2. Select RNA sequences

This opens the dialog displayed in figure 15.2:

![Figure 15.2: Translating RNA to DNA.](image)

If a sequence was selected before choosing the Toolbox action, this sequence is now listed in the *Selected Elements* window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements.

Click **Finish** to start the tool.

This will open a new view in the **View Area** displaying the new DNA sequence. The new sequence is not saved automatically. To save the sequence, drag it into the **Navigation Area** or press Ctrl + S (⌘ + S on Mac) to activate a save dialog.

**Note!** You can select multiple RNA sequences and sequence lists at a time. If the sequence list contains DNA sequences as well, they will not be converted.

## 15.3 Reverse complements of sequences

*CLC Genomics Workbench* is able to create the reverse complement of a nucleotide sequence. By doing that, a new sequence is created which also has all the annotations reversed since they now occupy the opposite strand of their previous location.

To quickly obtain the reverse complement of a sequence or part of a sequence, you may select a region on the negative strand and open it in a new view:
right-click a selection on the negative strand | Open selection in New View

By doing that, the sequence will be reversed. This is only possible when the double stranded view option is enabled. It is possible to copy the selection and paste it in a word processing program or an e-mail. To obtain a reverse complement of an entire sequence:

Toolbox | Classical Sequence Analysis | Nucleotide Analysis | Reverse Complement Sequence

This opens the dialog displayed in figure 15.3:

![Figure 15.3: Creating a reverse complement sequence.](image)

If a sequence was selected before choosing the Toolbox action, the sequence is now listed in the Selected Elements window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements.

Click Finish to start the tool.

This will open a new view in the View Area displaying the reverse complement of the selected sequence. The new sequence is not saved automatically. To save the sequence, drag it into the Navigation Area or press Ctrl + S (⌘ + S on Mac) to activate a save dialog.

15.4 Reverse sequence

**CLC Genomics Workbench** is able to create the reverse of a nucleotide sequence.

**Note!** This is not the same as a reverse complement. If you wish to create the reverse complement, please refer to section 15.3.

To run the tool, go to:

Toolbox | Classical Sequence Analysis | Nucleotide Analysis | Reverse Sequence

This opens the dialog displayed in figure 15.4:

If a sequence was selected before choosing the Toolbox action, the sequence is now listed in the Selected Elements window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements.

Click Finish to start the tool.

The Reverse Sequence tool will output reversed sequences holding the input sequences name with a "-R" suffix.
Note! This is not the same as a reverse complement. If you wish to create the reverse complement, please refer to section 15.3.

15.5 Translation of DNA or RNA to protein

In CLC Genomics Workbench you can translate a nucleotide sequence into a protein sequence using the Toolbox tools. Usually, you use the +1 reading frame which means that the translation starts from the first nucleotide. Stop codons result in an asterisk being inserted in the protein sequence at the corresponding position. It is possible to translate in any combination of the six reading frames in one analysis. To translate, go to:

Toolbox | Classical Sequence Analysis ( ) | Nucleotide Analysis ( ) | Translate to Protein ( )

This opens the dialog displayed in figure 15.5:

If a sequence was selected before choosing the Toolbox action, the sequence is now listed in the Selected Elements window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements.

Clicking Next generates the dialog seen in figure 15.6:

Here you have the following options:

Reading frames If you wish to translate the whole sequence, you must specify the reading frame for the translation. If you select e.g. two reading frames, two protein sequences are generated.

Translate CDS You can choose to translate regions marked by and CDS or ORF annotation. This will generate a protein sequence for each CDS or ORF annotation on the sequence. The
"Extract existing translations from annotation" allows to list the amino acid CDS sequence shown in the tool tip annotation (e.g. interstate from NCBI download) and does therefore not represent a translation of the actual nt sequence.

**Genetic code translation table** Lets you specify the genetic code for the translation. The translation tables are occasionally updated from NCBI. The tables are not available in this printable version of the user manual. Instead, the tables are included in the Help-menu in the **Menu Bar** (in the appendix).

Click **Finish** to start the tool. The newly created protein is shown, but is not saved automatically.

To save a protein sequence, drag it into the **Navigation Area** or press Ctrl + S (**⌘** + S on Mac) to activate a save dialog.

The name for a coding region translation consists of the name of the input sequence followed by the annotation type and finally the annotation name.

**Translate part of a nucleotide sequence** If you want to make separate translations of all the coding regions of a nucleotide sequence, you can check the option: "Translate CDS/ORF..." in the translation dialog (see figure 15.6).

If you want to translate a specific coding region, which is annotated on the sequence, use the following procedure:

Open the nucleotide sequence | right-click the ORF or CDS annotation | Translate CDS/ORF... (**)  

A dialog opens to offer you the following choices (figure 15.7): either a specific genetic code translation table, or to extract the existing translation from annotation (if the annotation contains information about the translation). Choose the option needed and click **Translate**.

The CDS and ORF annotations are colored yellow as default.
15.6 Find open reading frames

The CLC Genomics Workbench Find Open Reading Frames function can be used to find all open reading frames (ORF) in a sequence, or, by choosing particular start codons to use, it can be used as a rudimentary gene finder. ORFs identified will be shown as annotations on the sequence. You have the option of choosing a translation table, the start codons to use, minimum ORF length as well as a few other parameters. These choices are explained in this section.

To find open reading frames:

Toolbox | Classical Sequence Analysis | Nucleotide Analysis | Find Open Reading Frames

This opens the dialog displayed in figure 15.8:

If a sequence was selected before choosing the Toolbox action, the sequence is now listed in the Selected Elements window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements.

The Find Open Reading Frames tool simply looks for start and stop codons and reports any open reading frames that satisfy the parameters. If you want to adjust the parameters for finding open reading frames click Next.

15.6.1 Open reading frame parameters

This opens the dialog displayed in figure 15.9:

The adjustable parameters for the search are:
CHAPTER 15. NUCLEOTIDE ANALYSES

Figure 15.9: Parameters for the Reading Frame tool.

- **Start codon:**
  - **AUG.** Most commonly used start codon.
  - **Any.** Find all open reading frames of specified length. Any combination of three bases that is not a stop-codon is interpreted as a start codon, and translated according to the specified genetic code.
  - **All start codons in genetic code.**
  - **Other.** Here you can specify a number of start codons separated by commas.

- **Both strands.** Finds reading frames on both strands.

- **Open-ended Sequence.** Allows the ORF to start or end outside the sequence. If the sequence studied is a part of a larger sequence, it may be advantageous to allow the ORF to start or end outside the sequence.

- **Genetic code translation table.**

- **Include stop codon in result** The ORFs will be shown as annotations which can include the stop codon if this option is checked. The translation tables are occasionally updated from NCBI. The tables are not available in this printable version of the user manual. Instead, the tables are included in the Help menu in the Menu Bar (in the appendix).

- **Minimum Length.** Specifies the minimum length for the ORFs to be found. The length is specified as number of codons.

Using open reading frames for gene finding is a fairly simple approach which is likely to predict genes which are not real. Setting a relatively high minimum length of the ORFs will reduce the number of false positive predictions, but at the same time short genes may be missed (see figure 15.10).

Click **Finish** to start the tool.
Figure 15.10: The first 12,000 positions of the E. coli sequence NC_000913 downloaded from GenBank. The blue (dark) annotations are the genes while the yellow (brighter) annotations are the ORFs with a length of at least 100 amino acids. On the positive strand around position 11,000, a gene starts before the ORF. This is due to the use of the standard genetic code rather than the bacterial code. This particular gene starts with CTG, which is a start codon in bacteria. Two short genes are entirely missing, while a handful of open reading frames do not correspond to any of the annotated genes.

Finding open reading frames is often a good first step in annotating sequences such as cloning vectors or bacterial genomes. For eukaryotic genes, ORF determination may not always be very helpful since the intron/exon structure is not part of the algorithm.

CLC Genomics Workbench offers a number of analyses of proteins as described in this chapter.

16.1 Protein charge

In CLC Genomics Workbench you can create a graph in the electric charge of a protein as a function of pH. This is particularly useful for finding the net charge of the protein at a given pH. This knowledge can be used e.g. in relation to isoelectric focusing on the first dimension of 2D-gel electrophoresis. The isoelectric point (pI) is found where the net charge of the protein...
is zero. The calculation of the protein charge does not include knowledge about any potential post-translational modifications the protein may have.

The pKa values reported in the literature may differ slightly, thus resulting in different looking graphs of the protein charge plot compared to other programs.

In order to calculate the protein charge:

![Toolbox] Classical Sequence Analysis | Protein Analysis | Create Protein Charge Plot

This opens the dialog displayed in figure 16.1:

![Figure 16.1: Choosing protein sequences to calculate protein charge.]

If a sequence was selected before choosing the Toolbox action, the sequence is now listed in the Selected Elements window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements.

You can perform the analysis on several protein sequences at a time. This will result in one output graph showing protein charge graphs for the individual proteins.

Click Finish to start the tool.

Figure 16.2 shows the electrical charges for three proteins. In the Side Panel to the right, you can modify the layout of the graph.

![Figure 16.2: View of the protein charge.]

See section A in the appendix for information about the graph view.
16.2 Antigenicity

*CLC Genomics Workbench* can help to identify antigenic regions in protein sequences in different ways, using different algorithms. The algorithms provided in the Workbench, merely plot an index of antigenicity over the sequence.

Two different methods are available:

- [Welling et al., 1985] Welling et al. used information on the relative occurrence of amino acids in antigenic regions to make a scale which is useful for prediction of antigenic regions. This method is better than the Hopp-Woods scale of hydrophobicity which is also used to identify antigenic regions.

- A semi-empirical method for prediction of antigenic regions has been developed [Kolaskar and Tongaonkar, 1990]. This method also includes information of surface accessibility and flexibility and at the time of publication the method was able to predict antigenic determinants with an accuracy of 75%.

**Note!** Similar results from the two methods can not always be expected as the two methods are based on different training sets.

Displaying the antigenicity for a protein sequence in a plot is done in the following way:

Toolbox | Classical Sequence Analysis | Protein Analysis | Create Antigenicity Plot

This opens a dialog. The first step allows you to add or remove sequences. If you had already selected sequences in the Navigation Area before running the Toolbox action, these are shown in the **Selected Elements**. Clicking **Next** takes you through to **Step 2**, which is displayed in figure 16.3.

![Create Antigenicity Plot](image)

Figure 16.3: Step two in the Antigenicity Plot allows you to choose different antigenicity scales and the window size.

The **Window size** is the width of the window where, the antigenicity is calculated. The wider the window, the less volatile the graph. You can chose from a number of antigenicity scales. Click **Finish** to start the tool. The result can be seen in figure 16.4.

See section A in the appendix for information about the graph view.

The level of antigenicity is calculated on the basis of the different scales. The different scales add different values to each type of amino acid. The antigenicity score is then calculated as the sum of the values in a ‘window’, which is a particular range of the sequence. The window length
can be set from 5 to 25 residues. The wider the window, the less fluctuations in the antigenicity scores.

Antigenicity graphs along the sequence can be displayed using the Side Panel. The functionality is similar to hydrophobicity (see section 16.3.1).

### 16.3 Hydrophobicity

CLC Genomics Workbench can calculate the hydrophobicity of protein sequences in different ways, using different algorithms. (See section 16.3.2). Furthermore, hydrophobicity of sequences can be displayed as hydrophobicity plots and as graphs along sequences. In addition, CLC Genomics Workbench can calculate hydrophobicity for several sequences at the same time, and for alignments.

Displaying the hydrophobicity for a protein sequence in a plot is done in the following way:

- **Toolbox** | **Classical Sequence Analysis** | **Protein Analysis** | **Create Hydrophobicity Plot**

This opens a dialog. The first step allows you to add or remove sequences. If you had already selected a sequence in the Navigation Area, this will be shown in the Selected Elements. Clicking **Next** takes you through to **Step 2**, which is displayed in figure 16.5.

The **Window size** is the width of the window where the hydrophobicity is calculated. The wider the window, the less volatile the graph. You can chose from a number of hydrophobicity scales which are further explained in section 16.3.2 Click **Finish** to start the tool. The result can be seen in figure 16.6.

See section A in the appendix for information about the graph view.
16.3.1 Hydrophobicity graphs along sequence

Hydrophobicity graphs along sequence can be displayed easily by activating the calculations from the Side Panel for a sequence.

- right-click protein sequence in Navigation Area | Show | Sequence | open Protein info in Side Panel
- or double-click protein sequence in Navigation Area | Show | Sequence | open Protein info in Side Panel

These actions result in the view displayed in figure 16.7.

The level of hydrophobicity is calculated on the basis of the different scales. The different scales add different values to each type of amino acid. The hydrophobicity score is then calculated as the sum of the values in a ‘window’, which is a particular range of the sequence. The window length can be set from 5 to 25 residues. The wider the window, the less fluctuations in the hydrophobicity scores. (For more about the theory behind hydrophobicity, see 16.3.2).

In the following we will focus on the different ways that CLC Genomics Workbench offers to display the hydrophobicity scores. We use Kyte-Doolittle to explain the display of the scores, but the

![Figure 16.5: Step two in the Hydrophobicity Plot allows you to choose hydrophobicity scale and the window size.](image1)

![Figure 16.6: The result of the hydrophobicity plot calculation and the associated Side Panel.](image2)
different options are the same for all the scales. Initially there are three options for displaying the hydrophobicity scores. You can choose one, two or all three options by selecting the boxes. (See figure 16.8).

**Coloring the letters and their background.** When choosing coloring of letters or coloring of their background, the color red is used to indicate high scores of hydrophobicity. A 'color-slider' allows you to amplify the scores, thereby emphasizing areas with high (or low, blue) levels of hydrophobicity. The color settings mentioned are default settings. By clicking the color bar just below the color slider you get the option of changing color settings.

**Graphs along sequences.** When selecting graphs, you choose to display the hydrophobicity scores underneath the sequence. This can be done either by a line-plot or bar-plot, or by coloring. The latter option offers you the same possibilities of amplifying the scores as applies for coloring of letters. The different ways to display the scores when choosing 'graphs' are displayed in figure 16.8. Notice that you can choose the height of the graphs underneath the sequence.

### 16.3.2 Bioinformatics explained: Protein hydrophobicity

Calculation of hydrophobicity is important to the identification of various protein features. This can be membrane spanning regions, antigenic sites, exposed loops or buried residues. Usually, these calculations are shown as a plot along the protein sequence, making it easy to identify the
location of potential protein features.

Figure 16.9: Plot of hydrophobicity along the amino acid sequence. Hydrophobic regions on the sequence have higher numbers according to the graph below the sequence, furthermore hydrophobic regions are colored on the sequence. Red indicates regions with high hydrophobicity and blue indicates regions with low hydrophobicity.

The hydrophobicity is calculated by sliding a fixed size window (of an odd number) over the protein sequence. At the central position of the window, the average hydrophobicity of the entire window is plotted (see figure 16.9).

Hydrophobicity scales Several hydrophobicity scales have been published for various uses. Many of the commonly used hydrophobicity scales are described below.

Kyte-Doolittle scale. The Kyte-Doolittle scale is widely used for detecting hydrophobic regions in proteins. Regions with a positive value are hydrophobic. This scale can be used for identifying both surface-exposed regions as well as transmembrane regions, depending on the window size used. Short window sizes of 5-7 generally work well for predicting putative surface-exposed regions. Large window sizes of 19-21 are well suited for finding transmembrane domains if the values calculated are above 1.6 [Kyte and Doolittle, 1982]. These values should be used as a rule of thumb and deviations from the rule may occur.

Engelman scale. The Engelman hydrophobicity scale, also known as the GES-scale, is another scale which can be used for prediction of protein hydrophobicity [Engelman et al., 1986]. As the Kyte-Doolittle scale, this scale is useful for predicting transmembrane regions in proteins.

Eisenberg scale. The Eisenberg scale is a normalized consensus hydrophobicity scale which shares many features with the other hydrophobicity scales [Eisenberg et al., 1984].

Hopp-Woods scale. Hopp and Woods developed their hydrophobicity scale for identification of potentially antigenic sites in proteins. This scale is basically a hydrophilic index where apolar residues have been assigned negative values. Antigenic sites are likely to be predicted when using a window size of 7 [Hopp and Woods, 1983].

Cornette scale. Cornette et al. computed an optimal hydrophobicity scale based on 28 published scales [Cornette et al., 1987]. This optimized scale is also suitable for prediction of alpha-helices in proteins.

Rose scale. The hydrophobicity scale by Rose et al. is correlated to the average area of buried amino acids in globular proteins [Rose et al., 1985]. This results in a scale which is not showing the helices of a protein, but rather the surface accessibility.

Janin scale. This scale also provides information about the accessible and buried amino acid residues of globular proteins [Janin, 1979].

Welling scale. Welling et al. used information on the relative occurrence of amino acids in
### Table 16.1: Hydrophobicity scales

This table shows seven different hydrophobicity scales which are generally used for prediction of e.g. transmembrane regions and antigenicity.

antigenic regions to make a scale which is useful for prediction of antigenic regions. This method is better than the Hopp-Woods scale of hydrophobicity which is also used to identify antigenic regions.

**Kolaskar-Tongaonkar.** A semi-empirical method for prediction of antigenic regions has been developed [Kolaskar and Tongaonkar, 1990]. This method also includes information of surface accessibility and flexibility and at the time of publication the method was able to predict antigenic determinants with an accuracy of 75%.

**Surface Probability.** Display of surface probability based on the algorithm by [Emini et al., 1985]. This algorithm has been used to identify antigenic determinants on the surface of proteins.

**Chain Flexibility.** Display of backbone chain flexibility based on the algorithm by [Karplus and Schulz, 1985]. It is known that chain flexibility is an indication of a putative antigenic determinant.

Many more scales have been published throughout the last three decades. Even though more advanced methods have been developed for prediction of membrane spanning regions, the simple and very fast calculations are still highly used.

AAindex: Amino acid index database

### 16.4 Pfam domain search

With CLC Genomics Workbench you can perform a search for domains in protein sequences using the Pfam database. The Pfam database [Bateman et al., 2004] at http://pfam.sanger.ac.uk/ was initially developed to aid the annotation of the C. elegans genome. The database
is a large collection of multiple sequence alignments that cover 14831 protein domains and protein families as of March 2014. The database contains profile hidden Markov models (HMMs) for individual domain alignments, which can be used to quickly identify domains in protein sequences.

Many proteins have a unique combination of domains, which can be responsible for e.g. the catalytic activities of enzymes. Annotating sequences based on pairwise alignment methods by simply transferring annotation from a known protein to the unknown partner does not take domain organization into account [Galperin and Koonin, 1998]. For example, a protein may be annotated incorrectly as an enzyme if the pairwise alignment only finds a regulatory domain.

Using the Pfam Domain Search tool in CLC Genomics Workbench, you can search for domains in sequence data which otherwise do not carry any annotation information. The domain search is performed using the hmmsearch tool from the HMMER3 package version 3.1b1 (http://hmmer.janelia.org/). The Pfam search tool annotates protein sequences with all domains in the Pfam database that have a significant match. It is possible to lower the significance cutoff thresholds in the hmmsearch algorithm, which will reduce the number of domain annotations. Individual domain annotations can be removed manually as described in section 11.3.4.

16.4.1 Download of Pfam database

To be able to run the Pfam Domain Search tool you must first download the Pfam database. The Pfam database can be downloaded using:

Toolbox | Classical Sequence Analysis ( ) | Protein Analysis ( ) | Download Pfam Database ( )

Specify where you would like to save the downloaded Pfam database. The output of the Download Pfam Database tool is a database object, which can be selected as a parameter for the Pfam Domain Search tool. It doesn’t really make sense to try to open the database object directly from the Navigation Area as all you can see directly is the element history (which version of the Workbench that has been used and the name of the downloaded files) and the element info, which in this case only provides information about the database name.

16.4.2 Running Pfam Domain Search

When you have downloaded the Pfam database you are ready to perform a Pfam domain search. To do this start the Pfam search tool:

Toolbox | Classical Sequence Analysis ( ) | Protein Analysis ( ) | Pfam Domain Search ( )

If a sequence was selected before choosing the Toolbox action, this sequence is now listed in the Selected Elements window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements.

You can perform the analysis on several protein sequences at a time. This will add annotations to all the sequences. Click Next to adjust parameters (see figure 16.10).

• Database. Choose which database to use when searching for Pfam domains. For information on how to download a Pfam database see section 16.4.1
Figure 16.10: Setting parameters for Pfam Domain Search.

- **Significance cutoff**
  - **Use profile’s gathering cutoffs.** Use cutoffs specifically assigned to each family by the curator instead of manually assigning the **Significance cutoff.**
  - **Significance cutoff.** The E-value (expectation value) describes the number of hits one would expect to see by chance when searching a database of a particular size. Essentially, a hit with a low E-value is more significant compared to a hit with a high E-value. By lowering the significance threshold the domain search will become more specific and less sensitive, i.e. fewer hits will be reported but the reported hits will be more significant on average.

- **Remove overlapping matches from the same clan.** Perform post-processing of the results where overlaps between hits are resolved by keeping the hit with the smallest e-value.

Click **Next** to adjust the output of the tool. The Pfam search tool can produce two types of output. It can add annotations on the input sequences that show the domains found (see figure 16.11) and it can output a table with all the domains found.

Click **Finish** to start the tool.

![Figure 16.11: Annotations (in red) that were added by the Pfam search tool.](image)

Domain annotations added by the Pfam search tool have the type **Region.** If the annotations are not visible they have to be enabled in the side panel. Detailed information for each domain annotation, such as the bit score which is the basis for the prediction of domains, is available through the annotation tool tip.

A more detailed description of the scores provided in the annotation tool tips can be found here: [http://pfam.sanger.ac.uk/help#tabview=tab5](http://pfam.sanger.ac.uk/help#tabview=tab5).
16.5 Secondary structure prediction

An important issue when trying to understand protein function is to know the actual structure of the protein. Many questions that are raised by molecular biologists are directly targeted at protein structure. The alpha-helix forms a coiled rod like structure whereas a beta-sheet show an extended sheet-like structure. Some proteins are almost devoid of alpha-helices such as chymotrypsin (PDB ID: 1AB9) whereas others like myoglobin (PDB ID: 101M) have a very high content of alpha-helices.

With CLC Genomics Workbench one can predict the secondary structure of proteins very fast. Predicted elements are alpha-helix, beta-sheet (same as beta-strand) and other regions.

Based on extracted protein sequences from the protein databank (http://www.rcsb.org/pdb/) a hidden Markov model (HMM) was trained and evaluated for performance. Machine learning methods have shown superior when it comes to prediction of secondary structure of proteins [Rost, 2001]. By far the most common structures are Alpha-helices and beta-sheets which can be predicted, and predicted structures are automatically added to the query as annotation which later can be edited.

In order to predict the secondary structure of proteins:

Toolbox | Classical Sequence Analysis | Protein Analysis | Predict secondary structure

This opens the dialog displayed in figure 16.12:

![Predict Secondary Structure](image)

Figure 16.12: Choosing one or more protein sequences for secondary structure prediction.

If a sequence was selected before choosing the Toolbox action, this sequence is now listed in the Selected Elements window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements.

You can perform the analysis on several protein sequences at a time. This will add annotations to all the sequences and open a view for each sequence.

Click Finish to start the tool.

After running the prediction as described above, the protein sequence will show predicted alpha-helices and beta-sheets as annotations on the original sequence (see figure 16.13).

Each annotation will carry a tooltip note saying that the corresponding annotation is predicted with CLC Genomics Workbench. Additional notes can be added through the Edit Annotation right-click mouse menu. See section 11.3.2.

Undesired alpha-helices or beta-sheets can be removed through the Delete Annotation right-click mouse menu. See section 11.3.4.
16.6 Protein report

CLC Genomics Workbench is able to produce protein reports, a collection of some of the protein analyses described elsewhere in this manual.

To create a protein report do the following:

Toolbox | Classical Sequence Analysis | Protein Analysis | Create Protein Report

This opens a dialog where you can choose which proteins to create a report for. If you had already selected a sequence in the Navigation Area before running the Toolbox action, this will be shown in the Selected Elements. However, you can use the arrows to change this. When the correct one is chosen, click Next.

In the next dialog, you can choose which analyses you want to include in the report. The following list shows which analyses are available and explains where to find more details.

- **Sequence statistics.** Will produce a section called Protein statistics, as described in section 14.6.1.
- **Protein charge plot.** Plot of charge as function of pH, see section 16.1.
- **Hydrophobicity plot.** See section 16.3.
- **Complexity plot.** See section 14.5.
- **Dot plot.** See section 14.4.
- **Secondary structure prediction.** See section 16.5.
- **Pfam domain search.** See section 16.4.
- **BLAST against one or more sequences.** See section 12.1.2.
- **BLAST against NCBI databases.** See section 12.1.1.

When you have selected the relevant analyses, click Next. In the following dialogs, adjust the parameters for the different analyses you selected. The parameters are explained in more details in the relevant chapters or sections (mentioned in the list above).

For sequence statistics:

- **Individual Statistics Layout. Comparative** is disabled because reports are generated for one protein at a time.
• **Include Background Distribution of Amino Acids.** Includes distributions from different organisms. Background distributions are calculated from UniProt [www.uniprot.org](http://www.uniprot.org) version 6.0, dated September 13 2005.

For hydrophobicity plots:

• **Hydrophobicity scales.** Lets you choose between different scales.

• **Window size.** Width of window on sequence (it must be an odd number).

For complexity plots:

• **Window size.** Width of window on sequence (must be odd).

For dot plots:

• **Score model.** Different scoring matrices.

• **Window size.** Width of window on sequence.

For Pfam domain search:

• **Database and search type** lets you choose different databases and specify the search for full domains or fragments.

• **Significance cutoff** lets you set your E-value.

For BLAST search:

• **Program** lets you choose between different BLAST programs.

• **Target** lets you select the sequence(s) against which the BLAST should be targeted.

• **Database** lets you limit your search to a particular database.

Also set the BLAST parameters as explained in section 12.1.2.

For BLAST against NCBI databases:

• **Program** lets you choose between different BLAST programs.

• **Database** lets you limit your search to a particular database.

• **Genetic code** lets you choose a genetic code for the sequence or the database.

Also set the BLAST parameters as explained in section 12.1.1.

An example of Protein report can be seen in figure 16.14.

By double clicking a graph in the output, this graph is shown in a different view (CLC Genomics Workbench generates another tab). The report output and the new graph views can be saved by dragging the tab into the Navigation Area.

The content of the tables in the report can be copy/pasted out of the program and e.g. into Microsoft Excel. You can also [Export](#) the report in Excel format.
16.7 Reverse translation from protein into DNA

A protein sequence can be back-translated into DNA using CLC Genomics Workbench. Due to degeneracy of the genetic code every amino acid could translate into several different codons (only 20 amino acids but 64 different codons). Thus, the program offers a number of choices for determining which codons should be used. These choices are explained in this section. For background information see section 16.7.1.

In order to make a reverse translation:

Toolbox | Classical Sequence Analysis | Protein Analysis | Reverse Translate

This opens the dialog displayed in figure 16.15:

If a sequence was selected before choosing the Toolbox action, the sequence is now listed in the Selected Elements window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements. You can translate several protein sequences at a time.

Adjust the parameters for the translation in the dialog shown in figure 16.16.
Figure 16.16: Choosing parameters for the reverse translation.

- **Use random codon.** This will randomly back-translate an amino acid to a codon assuming the genetic code to be 1, but without using the codon frequency tables. Every time you perform the analysis you will get a different result.

- **Use only the most frequent codon.** On the basis of the selected translation table, this parameter/option will assign the codon that occurs most often. When choosing this option, the results of performing several reverse translations will always be the same, contrary to the other two options.

- **Use codon based on frequency distribution.** This option is a mix of the other two options. The selected translation table is used to attach weights to each codon based on its frequency. The codons are assigned randomly with a probability given by the weights. A more frequent codon has a higher probability of being selected. Every time you perform the analysis, you will get a different result. This option yields a result that is closer to the translation behavior of the organism (assuming you choose an appropriate codon frequency table).

- **Map annotations to reverse translated sequence.** If this checkbox is checked, then all annotations on the protein sequence will be mapped to the resulting DNA sequence. In the tooltip on the transferred annotations, there is a note saying that the annotation derives from the original sequence.

The **Codon Frequency Table** is used to determine the frequencies of the codons. Select a frequency table from the list that fits the organism you are working with. A translation table of an organism is created on the basis of counting all the codons in the coding sequences. Every codon in a **Codon Frequency Table** has its own count, frequency (per thousand) and fraction which are calculated in accordance with the occurrences of the codon in the organism. The tables provided were made using Codon Usage database [http://www.kazusa.or.jp/codon/](http://www.kazusa.or.jp/codon/) that was built on The NCBI-GenBank Flat File Release 160.0 [June 15 2007]. You can customize the list of codon frequency tables for your installation, see Appendix L.

Click **Finish** to start the tool. The newly created nucleotide sequence is shown, and if the analysis was performed on several protein sequences, there will be a corresponding number of views of nucleotide sequences.
16.7.1 Bioinformatics explained: Reverse translation

In all living cells containing hereditary material such as DNA, a transcription to mRNA and subsequent a translation to proteins occur. This is of course simplified but is in general what is happening in order to have a steady production of proteins needed for the survival of the cell. In bioinformatics analysis of proteins it is sometimes useful to know the ancestral DNA sequence in order to find the genomic localization of the gene. Thus, the translation of proteins back to DNA/RNA is of particular interest, and is called reverse translation or back-translation.

The Genetic Code In 1968 the Nobel Prize in Medicine was awarded to Robert W. Holley, Har Gobind Khorana and Marshall W. Nirenberg for their interpretation of the Genetic Code (http://nobelprize.org/medicine/laureates/1968/). The Genetic Code represents translations of all 64 different codons into 20 different amino acids. Therefore it is no problem to translate a DNA/RNA sequence into a specific protein. But due to the degeneracy of the genetic code, several codons may code for only one specific amino acid. This can be seen in the table below. After the discovery of the genetic code it has been concluded that different organism (and organelles) have genetic codes which are different from the "standard genetic code". Moreover, the amino acid alphabet is no longer limited to 20 amino acids. The 21st amino acid, selenocysteine, is encoded by an 'UGA' codon which is normally a stop codon. The discrimination of a selenocysteine over a stop codon is carried out by the translation machinery. Selenocysteines are very rare amino acids.

The table below shows the Standard Genetic Code which is the default translation table.

Solving the ambiguities of reverse translation A particular protein follows from the translation of a DNA sequence whereas the reverse translation need not have a specific solution according to the Genetic Code. The Genetic Code is degenerate which means that a particular amino acid can be translated into more than one codon. Hence there are ambiguities of the reverse translation.
In order to solve these ambiguities of reverse translation you can define how to prioritize the codon selection, e.g:

- Choose a codon randomly.
- Select the most frequent codon in a given organism.
- Randomize a codon, but with respect to its frequency in the organism.

As an example we want to translate an alanine to the corresponding codon. Four different codons can be used for this reverse translation; GCU, GCC, GCA or GCG. By picking either one by random choice we will get an alanine.

The most frequent codon, coding for an alanine in *E. coli* is GCG, encoding 33.7% of all alanines. Then comes GCC (25.5%), GCA (20.3%) and finally GCU (15.3%). The data are retrieved from the Codon usage database, see below. Always picking the most frequent codon does not necessarily give the best answer.

By selecting codons from a distribution of calculated codon frequencies, the DNA sequence obtained after the reverse translation, holds the correct (or nearly correct) codon distribution. It should be kept in mind that the obtained DNA sequence is not necessarily identical to the original one encoding the protein in the first place, due to the degeneracy of the genetic code.

In order to obtain the best possible result of the reverse translation, one should use the codon frequency table from the correct organism or a closely related species. The codon usage of the mitochondrial chromosome are often different from the native chromosome(s), thus mitochondrial codon frequency tables should only be used when working specifically with mitochondria.

### 16.8 Proteolytic cleavage detection

Given a protein sequence, *CLC Genomics Workbench* detects proteolytic cleavage sites in accordance with detection parameters and shows the detected sites as annotations on the sequence as well as in a table below the sequence view.

Detection of proteolytic cleavage sites is initiated by:

Toolbox | Classical Sequence Analysis | Protein Analysis | Proteolytic Cleavage

This opens the dialog shown in figure 16.17. You can select one or several sequences.

In the second dialog, you can select proteolytic cleavage enzymes. Presently, the list contains the enzymes shown in figure 16.18. The full list of enzymes and their cleavage patterns can be seen in Appendix, section C.
You can then set parameters for the detection. This limits the number of detected cleavages (figure 16.19).

- **Min. and max. number of cleavage sites.** Certain proteolytic enzymes cleave at many positions in the amino acid sequence. For instance proteinase K cleaves at nine different amino acids, regardless of the surrounding residues. Thus, it can be very useful to limit the number of actual cleavage sites before running the analysis.

- **Min. and max. fragment length** Likewise, it is possible to limit the output to only display sequence fragments between a chosen length. Both a lower and upper limit can be chosen.
• **Min. and max. fragment mass** The molecular weight is not necessarily directly correlated to the fragment length as amino acids have different molecular masses. For that reason it is also possible to limit the search for proteolytic cleavage sites to mass-range.

For example, if you have one protein sequence but you only want to show which enzymes cut between two and four times. Then you should select "The enzymes has more cleavage sites than 2" and select "The enzyme has less cleavage sites than 4". In the next step you should simply select all enzymes. This will result in a view where only enzymes which cut 2, 3 or 4 times are presented.

Click **Finish** to start the tool. The result of the detection is displayed in figure 16.20.

![Figure 16.20: The result of the proteolytic cleavage detection.](image)

Depending on the settings in the program, the output of the proteolytic cleavage site detection will display two views on the screen. The top view shows the actual protein sequence with the predicted cleavage sites indicated by small arrows. If no labels are found on the arrows they can be enabled by setting the labels in the "annotation layout" in the preference panel. The bottom view shows a text output of the detection, listing the individual fragments and information on these.

### 16.8.1 Bioinformatics explained: Proteolytic cleavage

Proteolytic cleavage is basically the process of breaking the peptide bonds between amino acids in proteins. This process is carried out by enzymes called peptidases, proteases or proteolytic cleavage enzymes.

Proteins often undergo proteolytic processing by specific proteolytic enzymes (proteases/peptidases) before final maturation of the protein. Proteins can also be cleaved as a result of intracellular processing of, for example, misfolded proteins. Another example of proteolytic processing of proteins is secretory proteins or proteins targeted to organelles, which have their signal peptide removed by specific signal peptidases before release to the extracellular environment or specific organelle.

Below a few processes are listed where proteolytic enzymes act on a protein substrate.
N-terminal methionine residues are often removed after translation.

- Signal peptides or targeting sequences are removed during translocation through a membrane.
- Viral proteins that were translated from a monocistronic mRNA are cleaved.
- Proteins or peptides can be cleaved and used as nutrients.
- Precursor proteins are often processed to yield the mature protein.

Proteolytic cleavage of proteins has shown its importance in laboratory experiments where it is often useful to work with specific peptide fragments instead of entire proteins.

Proteases also have commercial applications. As an example proteases can be used as detergents for cleavage of proteinaceous stains in clothing.

The general nomenclature of cleavage site positions of the substrate were formulated by Schechter and Berger, 1967-68 [Schechter and Berger, 1967], [Schechter and Berger, 1968]. They designate the cleavage site between P1-P1', incrementing the numbering in the N-terminal direction of the cleaved peptide bond (P2, P3, P4, etc.). On the carboxyl side of the cleavage site the numbering is incremented in the same way (P1', P2', P3' etc.). This is visualized in figure 16.21.

![Cleavage site diagram](image)

**Figure 16.21: Nomenclature of the peptide substrate. The substrate is cleaved between position P1-P1'**.

Proteases often have a specific recognition site where the peptide bond is cleaved. As an example trypsin only cleaves at lysine or arginine residues, but it does not matter (with a few exceptions) which amino acid is located at position P1' (carboxyterminal of the cleavage site). Another example is trombin which cleaves if an arginine is found in position P1, but not if a D or E is found in position P1' at the same time. (See figure 16.22).

Bioinformatics approaches are used to identify potential peptidase cleavage sites. Fragments can be found by scanning the amino acid sequence for patterns which match the corresponding cleavage site for the protease. When identifying cleaved fragments it is relatively important to know the calculated molecular weight and the isoelectric point.

CLC Genomics Workbench offers graphically and algorithmically advanced design of primers and probes for various purposes. This chapter begins with a brief introduction to the general concepts of the primer designing process. Then follows instructions on how to adjust parameters for primers, how to inspect and interpret primer properties graphically and how to interpret, save
and analyze the output of the primer design analysis. After a description of the different reaction
types for which primers can be designed, the chapter closes with sections on how to match
primers with other sequences and how to create a primer order.

17.1 Primer design - an introduction

Primer design can be accessed in two ways:

- Toolbox | Molecular Biology Tools ( ) | Primers and Probes ( ) | Design Primers ( ) | OK
- right-click sequence in Navigation Area | Show | Primer Designer ( )

In the primer view (see figure 17.1), the basic options for viewing the template sequence are the
same as for the standard sequence view (see section 11.1 for an explanation of these options).
This means that annotations such as known SNPs or exons can be displayed on the template
sequence to guide the choice of primer regions. In addition, traces in sequencing reads can be
shown along with the structure to guide the re-sequencing of poorly resolved regions.

Figure 17.1: The initial view of the sequence used for primer design.

17.1.1 General concept

The concept of the primer view is that the user first chooses the desired reaction type for the
session in the Primer Parameters preference group, e.g. Standard PCR. Reflecting the choice of
reaction type, it is now possibly to select one or more regions on the sequence and to use the
right-click mouse menu to designate these as primer or probe regions (see figure 17.2).

When a region is chosen, graphical information about the properties of all possible primers in
this region will appear in lines beneath it. By default, information is showed using a compact
mode but the user can change to a more detailed mode in the Primer information preference
group.

The number of information lines reflects the chosen length interval for primers and probes. In the
compact information mode one line is shown for every possible primer-length and each of these
lines contain information regarding all possible primers of the given length. At each potential
primer starting position, a circular information point is shown which indicates whether the primer
fulfills the requirements set in the primer parameters preference group. A green circle indicates
a primer which fulfils all criteria and a red circle indicates a primer which fails to meet one or
more of the set criteria. For more detailed information, place the mouse cursor over the circle representing the primer of interest. A tool-tip will then appear on screen, displaying detailed information about the primer in relation to the set criteria. To locate the primer on the sequence, simply left-click the circle using the mouse.

The various primer parameters can now be varied to explore their effect and the view area will dynamically update to reflect this allowing for a high degree of interactivity in the primer design process.

After having explored the potential primers the user may have found a satisfactory primer and choose to export this directly from the view area using a mouse right-click on the primers information point. This does not allow for any design information to enter concerning the properties of primer/probe pairs or sets e.g. primer pair annealing and $T_m$ difference between primers. If the latter is desired the user can use the **Calculate** button at the bottom of the Primer parameter preference group. This will activate a dialog, the contents of which depends on the chosen mode. Here, the user can set primer-pair specific setting such as allowed or desired $T_m$ difference and view the single-primer parameters which were chosen in the Primer parameters preference group.

Upon pressing finish, an algorithm will generate all possible primer sets and rank these based on their characteristics and the chosen parameters. A list will appear displaying the 100 most high scoring sets and information pertaining to these. The search result can be saved to the navigator. From the result table, suggested primers or primer/probe sets can be explored since clicking an entry in the table will highlight the associated primers and probes on the sequence. It is also possible to save individual primers or sets from the table through the mouse right-click menu. For a given primer pair, the amplified PCR fragment can also be opened or saved using the mouse right-click menu.
17.1.2 Scoring primers

CLC Genomics Workbench employs a proprietary algorithm to rank primer and probe solutions. The algorithm considers both the parameters pertaining to single oligos, such as e.g. the secondary structure score and parameters pertaining to oligo-pairs such as e.g. the oligo pair-annealing score. The ideal score for a solution is 100 and solutions are thus ranked in descending order. Each parameter is assigned an ideal value and a tolerance. Consider for example oligo self-annealing, here the ideal value of the annealing score is 0 and the tolerance corresponds to the maximum value specified in the side panel. The contribution to the final score is determined by how much the parameter deviates from the ideal value and is scaled by the specified tolerance. Hence, a large deviation from the ideal and a small tolerance will give a large deduction in the final score and a small deviation from the ideal and a high tolerance will give a small deduction in the final score.

17.2 Setting parameters for primers and probes

The primer-specific view options and settings are found in the Primer parameters preference group in the Side Panel to the right of the view (see figure 17.3).

![Figure 17.3: The two groups of primer parameters (in the program, the Primer information group is listed below the other group).](image)

17.2.1 Primer Parameters

In this preference group a number of criteria can be set, which the selected primers must meet. All the criteria concern single primers, as primer pairs are not generated until the Calculate button is pressed. Parameters regarding primer and probe sets are described in detail for each reaction mode (see below).

- **Length.** Determines the length interval within which primers can be designed by setting a maximum and a minimum length. The upper and lower lengths allowed by the program are 50 and 10 nucleotides respectively.

- **Melting temperature.** Determines the temperature interval within which primers must lie. When the Nested PCR or TaqMan reaction type is chosen, the first pair of melting temperature interval settings relate to the outer primer pair i.e. not the probe. Melting temperatures
are calculated by a nearest-neighbor model which considers stacking interactions between neighboring bases in the primer-template complex. The model uses state-of-the-art thermodynamic parameters [SantaLucia, 1998] and considers the important contribution from the dangling ends that are present when a short primer anneals to a template sequence [Bommarito et al., 2000]. A number of parameters can be adjusted concerning the reaction mixture and which influence melting temperatures (see below). Melting temperatures are corrected for the presence of monovalent cations using the model of [SantaLucia, 1998] and temperatures are further corrected for the presence of magnesium, deoxynucleotide triphosphates (dNTP) and dimethyl sulfoxide (DMSO) using the model of [von Ahsen et al., 2001].

- **Inner melting temperature.** This option is only activated when the Nested PCR or TaqMan mode is selected. In Nested PCR mode, it determines the allowed melting temperature interval for the inner/nested pair of primers, and in TaqMan mode it determines the allowed temperature interval for the TaqMan probe.

- **Advanced parameters.** A number of less commonly used options
  
  - **Buffer properties.** A number of parameters concerning the reaction mixture which influence melting temperatures.
    
    * **Primer concentration.** Specifies the concentration of primers and probes in units of nanomoles (nM). Note that in the case of a mix of primers, the concentration here refers to the individual primer and not the combined primers concentration.
    
    * **Salt concentration.** Specifies the concentration of monovalent cations ([NA⁺], [K⁺] and equivalents) in units of millimoles (mM)
    
    * **Magnesium concentration.** Specifies the concentration of magnesium cations ([Mg++] in units of millimoles (mM)
    
    * **dNTP concentration.** Specifies the combined concentration of all deoxynucleotide triphosphates in units of millimoles (mM)
    
    * **DMSO concentration.** Specifies the concentration of dimethyl sulfoxide in units of volume percent (vol. %)
  
  - **GC content.** Determines the interval of CG content (% C and G nucleotides in the primer) within which primers must lie by setting a maximum and a minimum GC content.
  
  - **Self annealing.** Determines the maximum self annealing value of all primers and probes. This determines the amount of base-pairing allowed between two copies of the same molecule. The self annealing score is measured in number of hydrogen bonds between two copies of primer molecules, with A-T base pairs contributing 2 hydrogen bonds and G-C base pairs contributing 3 hydrogen bonds.
  
  - **Self end annealing.** Determines the maximum self end annealing value of all primers and probes. This determines the number of consecutive base pairs allowed between the 3’ end of one primer and another copy of that primer. This score is calculated in number of hydrogen bonds (the example below has a score of 4 - derived from 2 A-T base pairs each with 2 hydrogen bonds).

AATTCCCTACAATCCCCAAA

||

AAACCCCTAAGATCCCCCTTAA
Secondary structure. Determines the maximum score of the optimal secondary DNA structure found for a primer or probe. Secondary structures are scored by the number of hydrogen bonds in the structure, and 2 extra hydrogen bonds are added for each stacking base-pair in the structure.

- 3’ end G/C restrictions. When this checkbox is selected it is possible to specify restrictions concerning the number of G and C molecules in the 3’ end of primers and probes. A low G/C content of the primer/probe 3’ end increases the specificity of the reaction. A high G/C content facilitates a tight binding of the oligo to the template but also increases the possibility of mispriming. Unfolding the preference groups yields the following options:
  - End length. The number of consecutive terminal nucleotides for which to consider the C/G content
  - Max no. of G/C. The maximum number of G and C nucleotides allowed within the specified length interval
  - Min no. of G/C. The minimum number of G and C nucleotides required within the specified length interval

- 5’ end G/C restrictions. When this checkbox is selected it is possible to specify restrictions concerning the number of G and C molecules in the 5’ end of primers and probes. A high G/C content facilitates a tight binding of the oligo to the template but also increases the possibility of mis-priming. Unfolding the preference groups yields the same options as described above for the 3’ end.

- Mode. Specifies the reaction type for which primers are designed:
  - Standard PCR. Used when the objective is to design primers, or primer pairs, for PCR amplification of a single DNA fragment.
  - Nested PCR. Used when the objective is to design two primer pairs for nested PCR amplification of a single DNA fragment.
  - Sequencing. Used when the objective is to design primers for DNA sequencing.
  - TaqMan. Used when the objective is to design a primer pair and a probe for TaqMan quantitative PCR.

Each mode is described further below.

- Calculate. Pushing this button will activate the algorithm for designing primers

17.3 Graphical display of primer information

The primer information settings are found in the Primer information preference group in the Side Panel to the right of the view (see figure 17.3).

There are two different ways to display the information relating to a single primer, the detailed and the compact view. Both are shown below the primer regions selected on the sequence.
17.3.1 Compact information mode

This mode offers a condensed overview of all the primers that are available in the selected region. When a region is chosen primer information will appear in lines beneath it (see figure 17.4).

The number of information lines reflects the chosen length interval for primers and probes. One line is shown for every possible primer-length, if the length interval is widened more lines will appear. At each potential primer starting position a circle is shown which indicates whether the primer fulfills the requirements set in the primer parameters preference group. A green primer indicates a primer which fulfills all criteria and a red primer indicates a primer which fails to meet one or more of the set criteria. For more detailed information, place the mouse cursor over the circle representing the primer of interest. A tool-tip will then appear on screen displaying detailed information about the primer in relation to the set criteria. To locate the primer on the sequence, simply left-click the circle using the mouse.

The various primer parameters can now be varied to explore their effect and the view area will dynamically update to reflect this. If e.g. the allowed melting temperature interval is widened more green circles will appear indicating that more primers now fulfill the set requirements and if e.g. a requirement for 3’ G/C content is selected, rec circles will appear at the starting points of the primers which fail to meet this requirement.

17.3.2 Detailed information mode

In this mode a very detailed account is given of the properties of all the available primers. When a region is chosen primer information will appear in groups of lines beneath it (see figure 17.5).

The number of information-line-groups reflects the chosen length interval for primers and probes. One group is shown for every possible primer length. Within each group, a line is shown for every primer property that is selected from the checkboxes in the primer information preference group. Primer properties are shown at each potential primer starting position and are of two types:

Properties with numerical values are represented by bar plots. A green bar represents the starting point of a primer that meets the set requirement and a red bar represents the starting point of a primer that fails to meet the set requirement:
Properties with Yes - No values. If a primer meets the set requirement a green circle will be shown at its starting position and if it fails to meet the requirement a red dot is shown at its starting position:

- C/G at 3’ end
- C/G at 5’ end

Common to both sorts of properties is that mouse clicking an information point (filled circle or bar) will cause the region covered by the associated primer to be selected on the sequence.

### 17.4 Output from primer design

The output generated by the primer design algorithm is a table of proposed primers or primer pairs with the accompanying information (see figure 17.6).

In the preference panel of the table, it is possible to customize which columns are shown in the table. See the sections below on the different reaction types for a description of the available information.

The columns in the output table can be sorted by the present information. For example the user can choose to sort the available primers by their score (default) or by their self annealing score, simply by right-clicking the column header.
The output table interacts with the accompanying primer editor such that when a proposed combination of primers and probes is selected in the table the primers and probes in this solution are highlighted on the sequence.

**Saving primers** Primer solutions in a table row can be saved by selecting the row and using the right-click menu. This opens a dialog that allows the user to save the primers to the desired location. Primers and probes are saved as DNA sequences in the program. This means that all available DNA analyzes can be performed on the saved primers. Furthermore, the primers can be edited using the standard sequence view to introduce e.g. mutations and restriction sites.

**Saving PCR fragments** The PCR fragment generated from the primer pair in a given table row can also be saved by selecting the row and using the right-click menu. This opens a dialog that allows the user to save the fragment to the desired location. The fragment is saved as a DNA sequence and the position of the primers is added as annotation on the sequence. The fragment can then be used for further analysis and included in e.g. an in-silico cloning experiment using the cloning editor.

**Adding primer binding annotation** You can add an annotation to the template sequence specifying the binding site of the primer: Right-click the primer in the table and select **Mark primer annotation on sequence**.
17.5 Standard PCR

This mode is used to design primers for a PCR amplification of a single DNA fragment.

In this mode the user must define either a Forward primer region, a Reverse primer region, or both. These are defined by making a selection on the sequence and right-clicking the selection. It is also possible to define a Region to amplify in which case a forward- and a reverse primer region are automatically placed so as to ensure that the designated region will be included in the PCR fragment. If areas are known where primers must not bind (e.g. repeat rich areas), one or more No primers here regions can be defined.

If two regions are defined, it is required that at least a part of the Forward primer region is located upstream of the Reverse primer region.

After exploring the available primers (see section 17.3) and setting the desired parameter values in the Primer Parameters preference group, the Calculate button will activate the primer design algorithm.

17.5.1 When a single primer region is defined

If only a single region is defined, only single primers will be suggested by the algorithm.

After pressing the Calculate button a dialog will appear (see figure 17.7).

![Figure 17.7: Calculation dialog for PCR primers when only a single primer region has been defined.](image)

The top part of this dialog shows the parameter settings chosen in the Primer parameters preference group which will be used by the design algorithm.

**Mispriming:** The lower part contains a menu where the user can choose to include mispriming as an exclusion criteria in the design process. If this option is selected the algorithm will search for competing binding sites of the primer within the rest of the sequence, to see if the primer would match to multiple locations. If a competing site is found (according to the parameters set), the primer will be excluded.

The adjustable parameters for the search are:
• **Exact match.** Choose only to consider exact matches of the primer, i.e. all positions must base pair with the template for mispriming to occur.

• **Minimum number of base pairs required for a match.** How many nucleotides of the primer that must base pair to the sequence in order to cause mispriming.

• **Number of consecutive base pairs required in 3’ end.** How many consecutive 3’ end base pairs in the primer that MUST be present for mispriming to occur. This option is included since 3’ terminal base pairs are known to be essential for priming to occur.

**Note!** Including a search for potential mispriming sites will prolong the search time substantially if long sequences are used as template and if the minimum number of base pairs required for a match is low. If the region to be amplified is part of a very long molecule and mispriming is a concern, consider extracting part of the sequence prior to designing primers.

### 17.5.2 When both forward and reverse regions are defined

If both a forward and a reverse region are defined, primer pairs will be suggested by the algorithm. After pressing the **Calculate** button a dialog will appear (see figure 17.8).

![Figure 17.8: Calculation dialog for PCR primers when two primer regions have been defined.](image)

Again, the top part of this dialog shows the parameter settings chosen in the Primer parameters preference group which will be used by the design algorithm. The lower part again contains a menu where the user can choose to include mispriming of both primers as a criteria in the design process (see section 17.5.1). The central part of the dialog contains parameters pertaining to primer pairs. Here three parameters can be set:

• **Maximum percentage point difference in G/C content** - if this is set at e.g. 5 points a pair of primers with 45% and 49% G/C nucleotides, respectively, will be allowed, whereas a pair of primers with 45% and 51% G/C nucleotides, respectively will not be included.
• Maximal difference in melting temperature of primers in a pair - the number of degrees Celsius that primers in a pair are all allowed to differ.

• Max hydrogen bonds between pairs - the maximum number of hydrogen bonds allowed between the forward and the reverse primer in a primer pair.

• Max hydrogen bonds between pair ends - the maximum number of hydrogen bonds allowed in the consecutive ends of the forward and the reverse primer in a primer pair.

• Maximum length of amplicon - determines the maximum length of the PCR fragment.

### 17.5.3 Standard PCR output table

If only a single region is selected the following columns of information are available:

• Sequence - the primer’s sequence.

• Score - measures how much the properties of the primer (or primer pair) deviates from the optimal solution in terms of the chosen parameters and tolerances. The higher the score, the better the solution. The scale is from 0 to 100.

• Region - the interval of the template sequence covered by the primer

• Self annealing - the maximum self annealing score of the primer in units of hydrogen bonds

• Self annealing alignment - a visualization of the highest maximum scoring self annealing alignment

• Self end annealing - the maximum score of consecutive end base-pairings allowed between the ends of two copies of the same molecule in units of hydrogen bonds

• GC content - the fraction of G and C nucleotides in the primer

• Melting temperature of the primer-template complex

• Secondary structure score - the score of the optimal secondary DNA structure found for the primer. Secondary structures are scored by adding the number of hydrogen bonds in the structure, and 2 extra hydrogen bonds are added for each stacking base-pair in the structure

• Secondary structure - a visualization of the optimal DNA structure found for the primer

If both a forward and a reverse region are selected a table of primer pairs is shown, where the above columns (excluding the score) are represented twice, once for the forward primer (designated by the letter F) and once for the reverse primer (designated by the letter R).

Before these, and following the score of the primer pair, are the following columns pertaining to primer pair information available:

• Pair annealing - the number of hydrogen bonds found in the optimal alignment of the forward and the reverse primer in a primer pair

• Pair annealing alignment - a visualization of the optimal alignment of the forward and the reverse primer in a primer pair.
17.6 Nested PCR

Nested PCR is a modification of Standard PCR, aimed at reducing product contamination due to the amplification of unintended primer binding sites (mispriming). If the intended fragment can not be amplified without interference from competing binding sites, the idea is to seek out a larger outer fragment which can be unambiguously amplified and which contains the smaller intended fragment. Having amplified the outer fragment to large numbers, the PCR amplification of the inner fragment can proceed and will yield amplification of this with minimal contamination.

Primer design for nested PCR thus involves designing two primer pairs, one for the outer fragment and one for the inner fragment.

In Nested PCR mode the user must thus define four regions a Forward primer region (the outer forward primer), a Reverse primer region (the outer reverse primer), a Forward inner primer region, and a Reverse inner primer region. These are defined by making a selection on the sequence and right-clicking the selection. If areas are known where primers must not bind (e.g. repeat rich areas), one or more No primers here regions can be defined.

It is required that the Forward primer region, is located upstream of the Forward inner primer region, that the Forward inner primer region, is located upstream of the Reverse inner primer region, and that the Reverse inner primer region, is located upstream of the Reverse primer region.

In Nested PCR mode the Inner melting temperature menu in the Primer parameters panel is activated, allowing the user to set a separate melting temperature interval for the inner and outer primer pairs.

After exploring the available primers (see section 17.3) and setting the desired parameter values in the Primer parameters preference group, the Calculate button will activate the primer design algorithm.

After pressing the Calculate button a dialog will appear (see figure 17.9).

The top and bottom parts of this dialog are identical to the Standard PCR dialog for designing primer pairs described above.

The central part of the dialog contains parameters pertaining to primer pairs and the comparison between the outer and the inner pair. Here five options can be set:

- Maximum percentage point difference in G/C content (described above under Standard PCR) - this criteria is applied to both primer pairs independently.
- Maximal difference in melting temperature of primers in a pair - the number of degrees Celsius that primers in a pair are all allowed to differ. This criteria is applied to both primer pairs independently.
- Maximum pair annealing score - the maximum number of hydrogen bonds allowed between
the forward and the reverse primer in a primer pair. This criteria is applied to all possible combinations of primers.

- Minimum difference in the melting temperature of primers in the inner and outer primer pair - all comparisons between the melting temperature of primers from the two pairs must be at least this different, otherwise the primer set is excluded. This option is applied to ensure that the inner and outer PCR reactions can be initiated at different annealing temperatures. Please note that to ensure flexibility there is no directionality indicated when setting parameters for melting temperature differences between inner and outer primer pair, i.e. it is not specified whether the inner pair should have a lower or higher $T_m$. Instead this is determined by the allowed temperature intervals for inner and outer primers that are set in the primer parameters preference group in the side panel. If a higher $T_m$ of inner primers is desired, choose a $T_m$ interval for inner primers which has higher values than the interval for outer primers.

- Two radio buttons allowing the user to choose between a fast and an accurate algorithm for primer prediction.

**Nested PCR output table** In nested PCR there are four primers in a solution, forward outer primer (FO), forward inner primer (FI), reverse inner primer (RI) and a reverse outer primer (RO).

The output table can show primer-pair combination parameters for all four combinations of primers and single primer parameters for all four primers in a solution (see section on Standard PCR for an explanation of the available primer-pair and single primer information).

The fragment length in this mode refers to the length of the PCR fragment generated by the inner primer pair, and this is also the PCR fragment which can be exported.
17.7 TaqMan

CLC Genomics Workbench allows the user to design primers and probes for TaqMan PCR applications.

TaqMan probes are oligonucleotides that contain a fluorescent reporter dye at the 5’ end and a quenching dye at the 3’ end. Fluorescent molecules become excited when they are irradiated and usually emit light. However, in a TaqMan probe the energy from the fluorescent dye is transferred to the quencher dye by fluorescence resonance energy transfer as long as the quencher and the dye are located in close proximity i.e. when the probe is intact. TaqMan probes are designed to anneal within a PCR product amplified by a standard PCR primer pair. If a TaqMan probe is bound to a product template, the replication of this will cause the Taq polymerase to encounter the probe. Upon doing so, the 5’ exonuclease activity of the polymerase will cleave the probe. This cleavage separates the quencher and the dye, and as a result the reporter dye starts to emit fluorescence.

The TaqMan technology is used in Real-Time quantitative PCR. Since the accumulation of fluorescence mirrors the accumulation of PCR products it can be monitored in real-time and used to quantify the amount of template initially present in the buffer.

The technology is also used to detect genetic variation such as SNP’s. By designing a TaqMan probe which will specifically bind to one of two or more genetic variants it is possible to detect genetic variants by the presence or absence of fluorescence in the reaction.

A specific requirement of TaqMan probes is that a G nucleotide can not be present at the 5’ end since this will quench the fluorescence of the reporter dye. It is recommended that the melting temperature of the TaqMan probe is about 10 degrees celsius higher than that of the primer pair.

Primer design for TaqMan technology involves designing a primer pair and a TaqMan probe. In TaqMan the user must thus define three regions: a Forward primer region, a Reverse primer region, and a TaqMan probe region. The easiest way to do this is to designate a TaqMan primer/probe region spanning the sequence region where TaqMan amplification is desired. This will automatically add all three regions to the sequence. If more control is desired about the placing of primers and probes the Forward primer region, Reverse primer region and TaqMan probe region can all be defined manually. If areas are known where primers or probes must not bind (e.g. repeat rich areas), one or more No primers here regions can be defined. The regions are defined by making a selection on the sequence and right-clicking the selection.

It is required that at least a part of the Forward primer region is located upstream of the TaqMan Probe region, and that the TaqMan Probe region, is located upstream of a part of the Reverse primer region.

In TaqMan mode the Inner melting temperature menu in the primer parameters panel is activated allowing the user to set a separate melting temperature interval for the TaqMan probe.

After exploring the available primers (see section 17.3) and setting the desired parameter values in the Primer Parameters preference group, the Calculate button will activate the primer design algorithm.

After pressing the Calculate button a dialog will appear (see figure 17.10) which is similar to the Nested PCR dialog described above (see section 17.6).

In this dialog the options to set a minimum and a desired melting temperature difference between
CHAPTER 17. PRIMERS

Figure 17.10: Calculation dialog for taqman primers.

outer and inner refers to primer pair and probe respectively.

Furthermore, the central part of the dialog contains an additional parameter

- Maximum length of amplicon - determines the maximum length of the PCR fragment generated in the TaqMan analysis.

**TaqMan output table** In TaqMan mode there are two primers and a probe in a given solution, forward primer (F), reverse primer (R) and a TaqMan probe (TP).

The output table can show primer/probe-pair combination parameters for all three combinations of primers and single primer parameters for both primers and the TaqMan probe (see section on Standard PCR for an explanation of the available primer-pair and single primer information).

The fragment length in this mode refers to the length of the PCR fragment generated by the primer pair, and this is also the PCR fragment which can be exported.

### 17.8 Sequencing primers

This mode is used to design primers for DNA sequencing.

In this mode the user can define a number of **Forward primer regions** and **Reverse primer regions** where a sequencing primer can start. These are defined by making a selection on the sequence and right-clicking the selection. If areas are known where primers must not bind (e.g. repeat rich areas), one or more **No primers here** regions can be defined.

No requirements are instated on the relative position of the regions defined.

After exploring the available primers (see section 17.3) and setting the desired parameter values in the Primer Parameters preference group, the **Calculate** button will activate the primer design algorithm.
After pressing the **Calculate** button a dialog will appear (see figure 17.11).

![Calculation dialog for sequencing primers.](image)

Figure 17.11: Calculation dialog for sequencing primers.

Since design of sequencing primers does not require the consideration of interactions between primer pairs, this dialog is identical to the dialog shown in **Standard PCR** mode when only a single primer region is chosen (see section 17.5 for a description).

**Sequencing primers output table** In this mode primers are predicted independently for each region, but the optimal solutions are all presented in one table. The solutions are numbered consecutively according to their position on the sequence such that the forward primer region closest to the 5’ end of the molecule is designated F1, the next one F2 etc.

For each solution, the single primer information described under **Standard PCR** is available in the table.

### 17.9 Alignment-based primer and probe design

**CLC Genomics Workbench** allows the user to design PCR primers and TaqMan probes based on an alignment of multiple sequences.

The primer designer for alignments can be accessed with:

```
Toolbox | Molecular Biology Tools | Primers and Probes | Design Primers
```

Or if the alignment is already open, click **Primer Designer** in the lower left part of the view.

In the alignment primer view (see figure 17.12), the basic options for viewing the template alignment are the same as for the standard view of alignments (see section 20 for an explanation of these options). This means that annotations such as known SNPs or exons can be displayed on the template sequence to guide the choice of primer regions.
17.9.1 Specific options for alignment-based primer and probe design

Compared to the primer view of a single sequence, the most notable difference is that the alignment primer view has no available graphical information. Furthermore, the selection boxes found to the left of the names in the alignment play an important role in specifying the oligo design process.

The Primer Parameters group in the Side Panel has the same options as the ones defined for primers design based on single sequences, but differs by the following submenus (see figure 17.12):

- In the Mode submenu, specify either:
  - Standard PCR. Used when the objective is to design primers, or primer pairs, for PCR amplification of a single DNA fragment.
  - TaqMan. Used when the objective is to design a primer pair and a probe set for TaqMan quantitative PCR.

- In the Primer solution submenu, specify requirements for the match of a PCR primer against the template sequences. These options are described further below. It contains the following options:
  - Perfect match
  - Allow degeneracy
  - Allow mismatches

The workflow when designing alignment based primers and probes is as follows (see figure 17.12):

- Use selection boxes to specify groups of included and excluded sequences. To select all the sequences in the alignment, right-click one of the selection boxes and choose Mark All.
- Mark either a single forward primer region, a single reverse primer region or both on the sequence (and perhaps also a TaqMan region). Selections must cover all sequences in
the included group. You can also specify that there should be no primers in a region (No Primers Here) or that a whole region should be amplified (Region to Amplify).

- Adjust parameters regarding single primers in the preference panel.
- Click the Calculate button.

### 17.9.2 Alignment based design of PCR primers

In this mode, a single or a pair of PCR primers are designed. CLC Genomics Workbench allows the user to design primers which will specifically amplify a group of included sequences but not amplify the remainder of the sequences, the excluded sequences. The selection boxes are used to indicate the status of a sequence, if the box is checked the sequence belongs to the included sequences, if not, it belongs to the excluded sequences. To design primers that are general for all primers in an alignment, simply add them all to the set of included sequences by checking all selection boxes. Specificity of priming is determined by criteria set by the user in the dialog box which is shown when the Calculate button is pressed (see below).

Different options can be chosen concerning the match of the primer to the template sequences in the included group:

- **Perfect match.** Specifies that the designed primers must have a perfect match to all relevant sequences in the alignment. When selected, primers will thus only be located in regions that are completely conserved within the sequences belonging to the included group.

- **Allow degeneracy.** Designs primers that may include ambiguity characters where heterogeneities occur in the included template sequences. The allowed fold of degeneracy is user defined and corresponds to the number of possible primer combinations formed by a degenerate primer. Thus, if a primer covers two 4-fold degenerate site and one 2-fold degenerate site the total fold of degeneracy is $4 \times 4 \times 2 = 32$ and the primer will, when supplied from the manufacturer, consist of a mixture of 32 different oligonucleotides. When scoring the available primers, degenerate primers are given a score which decreases with the fold of degeneracy.
• **Allow mismatches.** Designs primers which are allowed a specified number of mismatches to the included template sequences. The melting temperature algorithm employed includes the latest thermodynamic parameters for calculating $T_m$ when single-base mismatches occur.

When in Standard PCR mode, clicking the **Calculate** button will prompt the dialog shown in figure 17.14.

The top part of this dialog shows the single-primer parameter settings chosen in the Primer parameters preference group which will be used by the design algorithm.

The central part of the dialog contains parameters pertaining to primer specificity (this is omitted if all sequences belong to the included group). Here, three parameters can be set:

- Minimum number of mismatches - the minimum number of mismatches that a primer must have against all sequences in the excluded group to ensure that it does not prime these.
- Minimum number of mismatches in 3' end - the minimum number of mismatches that a primer must have in its 3’ end against all sequences in the excluded group to ensure that it does not prime these.
- Length of 3’ end - the number of consecutive nucleotides to consider for mismatches in the 3’ end of the primer.

The lower part of the dialog contains parameters pertaining to primer pairs (this is omitted when only designing a single primer). Here, three parameters can be set:

- Maximum percentage point difference in G/C content - if this is set at e.g. 5 points a pair of primers with 45% and 49% G/C nucleotides, respectively, will be allowed, whereas a pair of primers with 45% and 51% G/C nucleotides, respectively will not be included.
- Maximal difference in melting temperature of primers in a pair - the number of degrees Celsius that primers in a pair are all allowed to differ.
- Max hydrogen bonds between pairs - the maximum number of hydrogen bonds allowed between the forward and the reverse primer in a primer pair.
- Maximum length of amplicon - determines the maximum length of the PCR fragment.

The output of the design process is a table of single primers or primer pairs as described for primer design based on single sequences. These primers are specific to the included sequences in the alignment according to the criteria defined for specificity. The only novelty in the table, is that melting temperatures are displayed with both a maximum, a minimum and an average value to reflect that degenerate primers or primers with mismatches may have heterogeneous behavior on the different templates in the group of included sequences.

### 17.9.3 Alignment-based TaqMan probe design

**CLC Genomics Workbench** allows the user to design solutions for TaqMan quantitative PCR which consist of four oligos: a general primer pair which will amplify all sequences in the alignment, a specific TaqMan probe which will match the group of **included** sequences but **not** match
the excluded sequences and a specific TaqMan probe which will match the group of excluded sequences but not match the included sequences. As above, the selection boxes are used to indicate the status of a sequence, if the box is checked the sequence belongs to the included sequences, if not, it belongs to the excluded sequences. We use the terms included and excluded here to be consistent with the section above although a probe solution is presented for both groups. In TaqMan mode, primers are not allowed degeneracy or mismatches to any template sequence in the alignment, variation is only allowed/required in the TaqMan probes.

Pushing the Calculate button will cause the dialog shown in figure 17.15 to appear.

The top part of this dialog is identical to the Standard PCR dialog for designing primer pairs described above.

The central part of the dialog contains parameters to define the specificity of TaqMan probes. Two parameters can be set:

- Minimum number of mismatches - the minimum total number of mismatches that must exist between a specific TaqMan probe and all sequences which belong to the group not recognized by the probe.
- Minimum number of mismatches in central part - the minimum number of mismatches in the central part of the oligo that must exist between a specific TaqMan probe and all sequences which belong to the group not recognized by the probe.

The lower part of the dialog contains parameters pertaining to primer pairs and the comparison between the outer oligos(primers) and the inner oligos (TaqMan probes). Here, five options can be set:

- Maximum percentage point difference in G/C content (described above under Standard PCR).
- Maximal difference in melting temperature of primers in a pair - the number of degrees Celsius that primers in the primer pair are all allowed to differ.
- Maximum pair annealing score - the maximum number of hydrogen bonds allowed between the forward and the reverse primer in an oligo pair. This criteria is applied to all possible combinations of primers and probes.

- Minimum difference in the melting temperature of primer (outer) and TaqMan probe (inner) oligos - all comparisons between the melting temperature of primers and probes must be at least this different, otherwise the solution set is excluded.

- Desired temperature difference in melting temperature between outer (primers) and inner (TaqMan) oligos - the scoring function discounts solution sets which deviate greatly from this value. Regarding this, and the minimum difference option mentioned above, please note that to ensure flexibility there is no directionality indicated when setting parameters for melting temperature differences between probes and primers, i.e. it is not specified whether the probes should have a lower or higher \( T_m \). Instead this is determined by the allowed temperature intervals for inner and outer oligos that are set in the primer parameters preference group in the side panel. If a higher \( T_m \) of probes is required, choose a \( T_m \) interval for probes which has higher values than the interval for outer primers.

The output of the design process is a table of solution sets. Each solution set contains the following: a set of primers which are general to all sequences in the alignment, a TaqMan probe which is specific to the set of included sequences (sequences where selection boxes are checked) and a TaqMan probe which is specific to the set of excluded sequences (marked by *). Otherwise, the table is similar to that described above for TaqMan probe prediction on single sequences.

![Figure 17.15: Calculation dialog shown when designing alignment based TaqMan probes.](image)

### 17.10 Analyze primer properties

*CLC Genomics Workbench* can calculate and display the properties of predefined primers and probes:

[Toolbox](#)  |  [Molecular Biology Tools](#)  |  [Primers and Probes](#)  |  [Analyze Primer Properties](#)
If a sequence was selected before choosing the Toolbox action, this sequence is now listed in the Selected Elements window of the dialog. Use the arrows to add or remove a sequence from the selected elements. (Primers are represented as DNA sequences in the Navigation Area).

Clicking Next generates the dialog seen in figure 17.16:

![Figure 17.16: The parameters for analyzing primer properties.](image)

In the Concentrations panel a number of parameters can be specified concerning the reaction mixture and which influence melting temperatures:

- **Primer concentration.** Specifies the concentration of primers and probes in units of nanomoles (nM)
- **Salt concentration.** Specifies the concentration of monovalent cations ([\(Na^+\), \(K^+\)] and equivalents) in units of millimoles (mM)

In the Template panel the sequences of the chosen primer and the template sequence are shown. The template sequence is as default set to the reverse complement of the primer sequence i.e. as perfectly base-pairing. However, it is possible to edit the template to introduce mismatches which may affect the melting temperature. At each side of the template sequence a text field is shown. Here, the dangling ends of the template sequence can be specified. These may have an important affect on the melting temperature [Bommarito et al., 2000]

Click Finish to start the tool. The result is shown in figure 17.17:

![Figure 17.17: Properties of a primer.](image)
In the Side Panel you can specify the information to display about the primer. The information parameters of the primer properties table are explained in section 17.5.3.

### 17.11 Find binding sites and create fragments

In *CLC Genomics Workbench* you have the possibility of matching known primers against one or more DNA sequences or a list of DNA sequences. This can be applied to test whether a primer used in a previous experiment is applicable to amplify a homologous region in another species, or to test for potential mispriming. This functionality can also be used to extract the resulting PCR product when two primers are matched. This is particularly useful if your primers have extensions in the 5' end. Note that this tool is not meant to analyze rapidly high-throughput data. The maximum amount of sequences the tool will handle in a reasonable amount of time depends on your computer processing capabilities.

To search for primer binding sites:

![Toolbox](image)

If a sequence was already selected in the Navigation Area, this sequence is now listed in the Selected Elements window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements.

Click Next when all the sequence have been added.

**Note!** You should not add the primer sequences at this step.

#### 17.11.1 Binding parameters

This opens the dialog displayed in figure 17.18:

![Figure 17.18: Search parameters for finding primer binding sites.](image)

At the top, select one or more primers by clicking the browse button. In *CLC Genomics Workbench*, primers are just DNA sequences like any other, but there is a filter on the length of the sequence. Only sequences up to 400 bp can be added.

The **Match criteria** for matching a primer to a sequence are:
• **Exact match.** Choose only to consider exact matches of the primer, i.e. all positions must base pair with the template.

• **Minimum number of base pairs required for a match.** How many nucleotides of the primer that must base pair to the sequence in order to cause priming/mispriming.

• **Number of consecutive base pairs required in 3’ end.** How many consecutive 3’ end base pairs in the primer that MUST be present for priming/mispriming to occur. This option is included since 3’ terminal base pairs are known to be essential for priming to occur.

Note that the number of mismatches is reported in the output, so you will be able to filter on this afterwards (see below).

Below the match settings, you can adjust **Concentrations** concerning the reaction mixture. This is used when reporting melting temperatures for the primers.

- **Primer concentration.** Specifies the concentration of primers and probes in units of nanomoles (nM)
- **Salt concentration.** Specifies the concentration of monovalent cations ([Na⁺], [K⁺] and equivalents) in units of millimoles (mM)

### 17.11.2 Results - binding sites and fragments

Specify the output options as shown in figure **17.19**:

![Figure 17.19: Output options include reporting of binding sites and fragments.](image)

The output options are:

- **Add binding site annotations.** This will add annotations to the input sequences (see details below).
- **Create binding site table.** Creates a table of all binding sites. Described in details below.
- **Create fragment table.** Showing a table of all fragments that could result from using the primers. Note that you can set the minimum and maximum sizes of the fragments to be shown. The table is described in detail below.
Click **Finish** to start the tool.

An example of a **binding site annotation** is shown in figure 17.20.

The annotation has the following information:

- **Sequence of the primer.** Positions with mismatches will be in lower-case (see the fourth position in figure 17.20 where the primer has an `a` and the template sequence has a `T`).

- **Number of mismatches.**

- **Number of other hits on the same sequence.** This number can be useful to check specificity of the primer.

- **Binding region.** This region ends with the 3’ exact match and is simply the primer length upstream. This means that if you have 5’ extensions to the primer, part of the binding region covers sequence that will actually not be annealed to the primer.

An example of the **primer binding site table** is shown in figure 17.21.

The information here is the same as in the primer annotation and furthermore you can see additional information about melting temperature etc. by selecting the options in the **Side Panel**. See a more detailed description of this information in section 17.5.3. You can use this table to browse the binding sites. If you make a split view of the table and the sequence (see
section 2.1.6), you can browse through the binding positions by clicking in the table. This will cause the sequence view to jump to the position of the binding site.

An example of a fragment table is shown in figure 17.22.

The table first lists the names of the forward and reverse primers, then the length of the fragment and the region. The last column tells if there are other possible fragments fulfilling the length criteria on this sequence. This information can be used to check for competing products in the PCR. In the Side Panel you can show information about melting temperature for the primers as well as the difference between melting temperatures.

You can use this table to browse the fragment regions. If you make a split view of the table and the sequence (see section 2.1.6), you can browse through the fragment regions by clicking in the table. This will cause the sequence view to jump to the start position of the fragment.

There are some additional options in the fragment table. First, you can annotate the fragment on the original sequence. This is done by right-clicking (Ctrl-click on Mac) the fragment and choose Annotate Fragment as shown in figure 17.23.

This will put a PCR fragment annotations on the input sequence covering the region specified in the table. As you can see from figure 17.23, you can also choose to Open Fragment. This will create a new sequence representing the PCR product that would be the result of using these two primers. Note that if you have extensions on the primers, they will be used to construct the new sequence.
If you are doing restriction cloning using primers with restriction site extensions, you can use this functionality to retrieve the PCR fragment for us in the cloning editor (see section 19.3).

17.12 Order primers

To facilitate the ordering of primers and probes, CLC Genomics Workbench offers an easy way of displaying and saving a textual representation of one or more primers:

Toolbox | Molecular Biology Tools | Primers and Probes | Order Primers

This opens a dialog where you can choose primers to generate a textual representation of the primers (see figure 17.24).

The first line states the number of primers being ordered and after this follows the names and nucleotide sequences of the primers in 5’-3’ orientation. From the editor, the primer information can be copied and pasted to web forms or e-mails. This file can also be saved and exported as a text file.

Figure 17.24: A primer order for 4 primers.

18.9 Secondary peak calling ......................................................... 426

This chapter explains the features in CLC Genomics Workbench for handling data analysis of low-throughput conventional Sanger sequencing data. For analysis of high-throughput sequencing data, please refer to part IV.

This chapter first explains how to trim sequence reads. Next follows a description of how to assemble reads into contigs both with and without a reference sequence. In the final section, the options for viewing and editing contigs are explained.
18.1 Importing and viewing trace data

A number of different binary trace data formats can be imported into the program, including Standard Chromatogram Format (.SCF), ABI sequencer data files (.ABI and .AB1), PHRED output files (.PHD) and PHRAP output files (.ACE) (see section 6.1).

After import, the sequence reads and their trace data are saved as DNA sequences. This means that all analyses that apply to DNA sequences can be performed on the sequence reads.

You can see additional information about the quality of the traces by holding the mouse cursor on the imported sequence. This will display a tool tip as shown in figure 18.1.

Figure 18.1: A tooltip displaying information about the quality of the chromatogram.

The qualities are based on the phred scoring system, with scores below 19 counted as low quality, scores between 20 and 39 counted as medium quality, and those 40 and above counted as high quality.

If the trace file does not contain information about quality, only the sequence length will be shown.

To view the trace data, open the sequence read in a standard sequence view.

The traces can be scaled by dragging the trace vertically as shown in figure 18.2. The Workbench automatically adjust the height of the traces to be readable, but if the trace height varies a lot, this manual scaling is very useful.

The height of the area available for showing traces can be adjusted in the Side Panel as described in section 18.1.1.

Figure 18.2: Grab the traces to scale.

18.1.1 Trace settings in the Side Panel

In the Nucleotide info preference group the display of trace data can be selected and unselected. When selected, the trace data information is shown as a plot beneath the sequence. The appearance of the plot can be adjusted using the following options (see figure 18.3):

- **Nucleotide trace.** For each of the four nucleotides the trace data can be selected and unselected.
- **Scale traces.** A slider which allows the user to scale the height of the trace area. Scaling the traces individually is described in section 18.1.
When working with stand-alone mappings containing reads with trace data, you can view the traces by turning on the trace setting options as described here and choosing Not compact in the Read layout setting for the mapping.

Please see section 25.2.3.

18.2 Trim sequences

Trimming as described in this section involves marking of low quality and/or vector sequence with a Trim annotation as shown in figure 18.4. Such annotated regions are then ignored when using downstream analysis tools located in the same section of the Workbench toolbox, for example Assembly (see section 18.3). The trimming described here annotates, but does not remove data, allowing you to explore the output of different trimming schemes easily.

Trimming as a separate task can be done manually or using a tool designed specifically for this task.

To remove existing trimming information from a sequence, simply remove its trim annotation (see section 11.3.2).

Note! If you wish to remove regions that are trimmed, you should instead use the NGS trim tool (see section 24.2).

When exporting sequences in fasta format, there is an option to remove the parts of the sequence...
18.2.1  Trimming using the Trim tool

Sequence reads can be trimmed based on a number of different criteria. Using a trimming tool for this is particularly useful if:

- You have many sequences to trim.
- You wish to trim vector contamination from sequencing reads.
- You wish to ensure that consistency when trimming. That is, you wish to ensure the same criteria are used for all the sequences in a set.

To start up the Trim tool in the Workbench, go to the menu option:

Toolbox | Molecular Biology Tools ( ) | Sanger Sequencing Analysis ( ) | Trim Sequences ( )

This opens a dialog where you can choose the sequences to trim, by using the arrows to move them between the Navigation Area and the 'Selected Elements' box.

You can then specify the trim parameters as displayed in figure 18.5.

![Figure 18.5: Setting parameters for trimming.](image)

The following parameters can be adjusted in the dialog:

- **Ignore existing trim information.** If you have previously trimmed the sequences, you can check this to remove existing trimming annotation prior to analysis.

- **Trim using quality scores.** If the sequence files contain quality scores from a base caller algorithm this information can be used for trimming sequence ends. The program uses the modified-Mott trimming algorithm for this purpose (Richard Mott, personal communication):

  Quality scores in the Workbench are on a Phred scale, and formats using other scales will be converted during import. The Phred quality scores \( Q \), defined as:

  \[ Q = -10 \log_{10}(P) \]

  where \( P \) is the base-calling error probability, can then be used to calculate the error probabilities, which in turn can be used to set the limit for, which bases should be trimmed.
Hence, the first step in the trim process is to convert the quality score \( Q \) to an error probability: 
\[
    p_{\text{error}} = 10^{-\frac{Q}{10}}.
\]
(This now means that low values are high quality bases.)

Next, for every base a new value is calculated: 
\[
    \text{Limit} - p_{\text{error}}.
\]
This value will be negative for low quality bases, where the error probability is high.

For every base, the Workbench calculates the running sum of this value. If the sum drops below zero, it is set to zero. The part of the sequence not trimmed will be the region ending at the highest value of the running sum and starting at the last zero value before this highest score. Everything before and after this region will be trimmed. A read will be completely removed if the score never makes it above zero.

- **Trim ambiguous nucleotides.** This option trims the sequence ends based on the presence of ambiguous nucleotides (typically N). Note that the automated sequencer generating the data must be set to output ambiguous nucleotides in order for this option to apply. The algorithm takes as input the maximal number of ambiguous nucleotides allowed in the sequence after trimming. If this maximum is set to e.g. 3, the algorithm finds the maximum length region containing 3 or fewer ambiguities and then trims away the ends not included in this region. The "Trim ambiguous nucleotides" option trims all types of ambiguous nucleotides (see Appendix G).

- **Trim contamination from vectors in UniVec database.** If selected, the program will match the sequence reads against all vectors in the UniVec database and mark sequence ends with significant matches with a 'Trim' annotation (the database is included when you install the CLC Genomics Workbench). A list of all the vectors in the UniVec database can be found at [http://www.ncbi.nlm.nih.gov/VecScreen/replist.html](http://www.ncbi.nlm.nih.gov/VecScreen/replist.html).

  - **Hit limit.** Specifies how strictly vector contamination is trimmed. Since vector contamination usually occurs at the beginning or end of a sequence, different criteria are applied for terminal and internal matches. A match is considered terminal if it is located within the first 25 bases at either sequence end. Three match categories are defined according to the expected frequency of an alignment with the same score occurring between random sequences. The CLC Genomics Workbench uses the same settings as VecScreen ([http://www.ncbi.nlm.nih.gov/VecScreen/VecScreen.html](http://www.ncbi.nlm.nih.gov/VecScreen/VecScreen.html)):
    - **Weak.** Expect 1 random match in 40 queries of length 350 kb
      - Terminal match with Score 16 to 18.
      - Internal match with Score 23 to 24.
    - **Moderate.** Expect 1 random match in 1,000 queries of length 350 kb
      - Terminal match with Score 19 to 23.
      - Internal match with Score 25 to 29.
    - **Strong.** Expect 1 random match in 1,000,000 queries of length 350 kb
      - Terminal match with Score \( \geq 24 \).
      - Internal match with Score \( \geq 30 \).

    Note that selecting **Weak** will also include matches in the **Moderate** and **Strong** categories.

- **Trim contamination from saved sequences.** This option lets you select your own vector sequences that you have imported into the Workbench. If you select this option, you will be able to select one or more sequences when you click **Next**.
Click **Finish** to start the tool. This will start the trimming process. Views of each trimmed sequence will be shown, and you can inspect the result by looking at the "Trim" annotations (they are colored red as default). Note that the trim annotations are used to signal that this part of the sequence is to be ignored during further analyses, hence the trimmed sequences are not deleted. If there are no trim annotations, the sequence has not been trimmed.

### 18.2.2 Manual trimming

Sequence reads can be trimmed manually while inspecting their trace and quality data.

Trimming sequences manually involves adding an annotation of type Trim, with the special condition that this annotation can only be applied to the ends of a sequence:

- **double-click the sequence to trim in the Navigation Area**
- **select the region you want to trim**
- **right-click the selection**
- **Trim sequence left/right to determine the direction of the trimming**

This will add a trimming annotation to the end of the sequence in the selected direction. No sequence is being deleted here. Rather, the regions covered by trim annotations are noted by downstream analyses (in the same section of the Workbench Toolbox as the Trim tool) as regions to be ignored.

### 18.3 Assemble sequences

This section describes how to assemble a number of sequence reads into a contig without the use of a reference sequence (a known sequence that can be used for comparison with the other sequences, see section 18.4).

**Note!** You can assemble a maximum of 10,000 sequences at a time.

To assemble more sequences, please use the **De Novo Assembly** tool under **De Novo Sequencing** in the Toolbox instead.

To perform the assembly:

1. **Toolbox** | **Molecular Biology Tools** | **Sanger Sequencing Analysis** | **Assemble Sequences**

This will open a dialog where you can select sequences to assemble. If you already selected sequences in the Navigation Area, these will be shown in 'Selected Elements'. You can alter your choice of sequences to assemble, or add others, by using the arrows to move sequences between the Navigation Area and the 'Selected Elements' box. You can also add sequence lists.

When the sequences are selected, click **Next**. This will show the dialog in figure 18.6

This dialog gives you the following options for assembly:

- **Minimum aligned read length.** The minimum number of nucleotides in a read which must be successfully aligned to the contig. If this criteria is not met by a read, the read is excluded from the assembly.

- **Alignment stringency.** Specifies the stringency (Low, Medium or High) of the scoring function used by the alignment step in the contig assembly algorithm. A higher stringency
level will tend to produce contigs with fewer ambiguities but will also tend to omit more sequencing reads and to generate more and shorter contigs.

- **Conflicts.** If there is a conflict, i.e. a position where there is disagreement about the residue (A, C, T or G), you can specify how the contig sequence should reflect the conflict:
  
  - **Vote (A, C, G, T).** The conflict will be solved by counting instances of each nucleotide and then letting the majority decide the nucleotide in the contig. In case of equality, ACGT are given priority over one another in the stated order.
  
  - **Unknown nucleotide (N).** The contig will be assigned an 'N' character in all positions with conflicts (conflicts are registered already when two nucleotides differ).
  
  - **Ambiguity nucleotides (R, Y, etc.).** The contig will display an ambiguity nucleotide reflecting the different nucleotides found in the reads (nucleotide ambiguity is registered already when two nucleotides differ). For an overview of ambiguity codes, see Appendix G.

Note, that conflicts will always be highlighted no matter which of the options you choose. Furthermore, each conflict will be marked as annotation on the contig sequence and will be present if the contig sequence is extracted for further analysis. As a result, the details of any experimental heterogeneity can be maintained and used when the result of single-sequence analyzes is interpreted. Read more about conflicts in section 18.7.4.

- **Create full contigs, including trace data.** This will create a contig where all the aligned reads are displayed below the contig sequence. (You can always extract the contig sequence without the reads later on.) For more information on how to use the contigs that are created, see section 18.7.

- **Show tabular view of contigs.** A contig can be shown both in a graphical as well as a tabular view. If you select this option, a tabular view of the contig will also be opened (Even if you do not select this option, you can show the tabular view of the contig later on by clicking Table at the bottom of the view.) For more information about the tabular view of contigs, see section 18.7.7.

- **Create only consensus sequences.** This will not display a contig but will only output the assembled contig sequences as single nucleotide sequences. If you choose this option it is not possible to validate the assembly process and edit the contig based on the traces.
When the assembly process has ended, a number of views will be shown, each containing a contig of two or more sequences that have been matched. If the number of contigs seem too high or low, try again with another Alignment stringency setting. Depending on your choices of output options above, the views will include trace files or only contig sequences. However, the calculation of the contig is carried out the same way, no matter how the contig is displayed.

See section 18.7 on how to use the resulting contigs.

**18.4 Assemble sequences to reference**

This section describes how to assemble a number of sequence reads into a contig using a reference sequence, a process called read mapping. A reference sequence can be particularly helpful when the objective is to characterize SNP variation in the data.

**Note!** You can assemble a maximum of 10,000 sequences at a time.

To assemble more sequences, please use the Map Reads to Reference under Resequencing Analysis in the Toolbox.

To start the assembly:

**Toolbox | Molecular Biology Tools | Sanger Sequencing Analysis | Assemble Sequences to Reference**

This opens a dialog where you can alter your choice of sequences to assemble. If you have already selected sequences in the Navigation Area, these will be shown in Selected Elements, however you can remove these or add others, by using the arrows to move sequences between the Navigation Area and Selected Elements boxes. You can also add sequence lists.

When the sequences are selected, click **Next**, and you will see the dialog shown in figure 18.7

![Parameter dialog for assembling sequences to a reference sequence.](image)

Figure 18.7: Parameters for how the reference should be handled when assembling sequences to a reference sequence.

This dialog gives you the following options for assembling:

- **Reference sequence.** Click the **Browse and select element** icon in order to select one or more sequences to use as reference(s).

- **Include reference sequence(s) in contig(s).** This will create a contig for each reference with
the corresponding reference sequence at the top and the aligned sequences below. This option is useful when comparing sequence reads to a closely related reference sequence e.g. when sequencing for SNP characterization.

- **Only include part of reference sequence(s) in the contig(s).** If the aligned sequences only cover a small part of a reference sequence, it may not be desirable to include the whole reference sequence in a contig. When this option is selected, you can specify the number of residues from reference sequences that should be included on each side of regions spanned by aligned sequences using the Extra residues field.

- **Do not include reference sequence(s) in contig(s).** This will produce contigs without any reference sequence where the input sequences have been assembled using reference sequences as a scaffold. The input sequences are first aligned to the reference sequence(s). Next, the consensus sequence for regions spanned by aligned sequences are extracted and output as contigs. This option is useful when performing assembling sequences where the reference sequences that are not closely related to the input sequencing.

When the reference sequence has been selected, click Next, to see the dialog shown in figure 18.8

![Figure 18.8: Options for how the input sequences should be aligned and how nucleotide conflicts should be handled.](image)

In this dialog, you can specify the following options:

- **Minimum aligned read length.** The minimum number of nucleotides in a read which must match a reference sequence. If an input sequence does not meet this criteria, the sequence is excluded from the assembly.

- **Alignment stringency.** Specifies the stringency (Low, Medium or High) of the scoring function used for aligning the input sequences to the reference sequence(s). A higher stringency level often produce contigs with lower levels of ambiguity but also reduces the ability to align distant homologs or sequences with a high error rate to reference sequences. The result of a higher stringency level is often that the number of contigs increases and the average length of contigs decreases while the quality of each contig increases.

The stringency settings Low, Medium and High are based on the following score values (mt=match, ti=transition, tv=transversion, un=unknown):
### Score values

<table>
<thead>

### Conflicts resolution

- **Unknown nucleotide (N).** The contig will be assigned an 'N' character in all positions with conflicts (conflicts are registered already when two nucleotides differ).

- **Ambiguity nucleotides (R, Y, etc.).** The contig will display an ambiguity nucleotide reflecting the different nucleotides found in the aligned sequences (nucleotide ambiguity is registered when two nucleotides differ). For an overview of ambiguity codes, see Appendix G.

- **Vote (A, C, G, T).** The conflict will be solved by counting instances of each nucleotide and then letting the majority decide the nucleotide in the contig. In case of equality, ACGT are given priority over one another in the stated order.

Note, that conflicts will be highlighted for all options. Furthermore, conflicts will be marked with an annotation on each contig sequence which are preserved if the contig sequence is extracted for further analysis. As a result, the details of any experimental heterogeneity can be maintained and used when the result of single-sequence analyzes is interpreted.

### Trimming options

When aligning sequences to a reference sequence, trimming is generally not necessary, but if you wish to use trimming you can check this box. It requires that the sequence reads have been trimmed beforehand (see section 18.2 for more information about trimming).

Click **Finish** to start the tool. This will start the assembly process. See section 18.7 on how to use the resulting contigs.

### 18.5 Sort sequences by name

With this functionality you will be able to group sequencing reads based on their file name. A typical example would be that you have a list of files named like this:
... 
A02__Asp_F_016_2007-01-10
A02__Asp_R_016_2007-01-10
A02__Gln_F_016_2007-01-11
A02__Gln_R_016_2007-01-11
A03__Asp_F_031_2007-01-10
A03__Asp_R_031_2007-01-10
A03__Gln_F_031_2007-01-11
A03__Gln_R_031_2007-01-11
...

In this example, the names have five distinct parts (we take the first name as an example):

- **A02** which is the position on the 96-well plate
- **Asp** which is the name of the gene being sequenced
- **F** which describes the orientation of the read (forward/reverse)
- **016** which is an ID identifying the sample
- **2007-01-10** which is the date of the sequencing run

To start mapping these data, you probably want to have them divided into groups instead of having all reads in one folder. If, for example, you wish to map each sample separately, or if you wish to map each gene separately, you cannot simply run the mapping on all the sequences in one step.

That is where **Sort Sequences by Name** comes into play. It will allow you to specify which part of the name should be used to divide the sequences into groups. We will use the example described above to show how it works:

**Toolbox** | **Molecular Biology Tools (.SetParent) | Sanger Sequencing Analysis (SetSelection) | Sort Sequences by Name** (SetSelected)

This opens a dialog where you can add the sequences you wish to sort, by using the arrows to move them between the Navigation Area and 'Selected Elements'. You can also add sequence lists or the contents of an entire folder by right-clicking the folder and choose: **Add folder contents**.

When you click **Next**, you will be able to specify the details of how the grouping should be performed. First, you have to choose how each part of the name should be identified. There are three options:

- **Simple.** This will simply use a designated character to split up the name. You can choose a character from the list:
  - Underscore _
  - Dash -
  - Hash (number sign / pound sign) #
  - Pipe |
- Tilde ~
- Dot .

- **Positions**. You can define a part of the name by entering the start and end positions, e.g. from character number 6 to 14. For this to work, the names have to be of equal lengths.

- **Java regular expression**. This is an option for advanced users where you can use a special syntax to have total control over the splitting. See more below.

In the example above, it would be sufficient to use a simple split with the underscore _ character, since this is how the different parts of the name are divided.

When you have chosen a way to divide the name, the parts of the name will be listed in the table at the bottom of the dialog. There is a checkbox next to each part of the name. This checkbox is used to specify which of the name parts should be used for grouping. In the example above, if we want to group the reads according to date and analysis position, these two parts should be checked as shown in figure 18.9.

**Figure 18.9:** Splitting up the name at every underscore (_) and using the date and analysis position for grouping.

At the middle of the dialog there is a preview panel listing:

- **Sequence name**. This is the name of the first sequence that has been chosen. It is shown here in the dialog in order to give you a sample of what the names in the list look like.

- **Resulting group**. The name of the group that this sequence would belong to if you proceed with the current settings.

- **Number of sequences**. The number of sequences chosen in the first step.

- **Number of groups**. The number of groups that would be produced when you proceed with the current settings.
This preview cannot be changed. It is shown to guide you when finding the appropriate settings.

Click **Finish** to start the tool. A new sequence list will be generated for each group. It will be named according to the group, e.g. `2004-08-24_A02` will be the name of one of the groups in the example shown in figure 18.9.

**Advanced splitting using regular expressions**

You can see a more detail explanation of the regular expressions syntax in section 14.9.3.

In this section you will see a practical example showing how to create a regular expression. Consider a list of files as shown below:

```plaintext
...
adk-29_adk1n-F
adk-29_adk2n-R
adk-3_adk1n-F
adk-3_adk2n-R
adk-66_adk1n-F
adk-66_adk2n-R
atp-29_atpA1n-F
atp-29_atpA2n-R
atp-3_atpA1n-F
atp-3_atpA2n-R
atp-66_atpA1n-F
atp-66_atpA2n-R
...
```

In this example, we wish to group the sequences into three groups based on the number after the "-" and before the "_" (i.e. 29, 3 and 66). The simple splitting as shown in figure 18.9 requires the same character before and after the text used for grouping, and since we now have both a "-" and a "_", we need to use the regular expressions instead (note that dividing by position would not work because we have both single and double digit numbers (3, 29 and 66)).

The regular expression for doing this would be `(.*)-(.*)(_.*))` as shown in figure 18.10.

The round brackets () denote the part of the name that will be listed in the groups table at the bottom of the dialog. In this example we actually did not need the first and last set of brackets, so the expression could also have been `.*-(.*)_.*` in which case only one group would be listed in the table at the bottom of the dialog.

### 18.6 Add sequences to an existing contig

This section describes how to assemble sequences to an existing contig. This feature can be used for example to provide a steady work-flow when a number of exons from the same gene are sequenced one at a time and assembled to a reference sequence.

Note that the new sequences will be added to the existing contig which will not be extended. If the new sequences extend beyond the existing contig, they will be cut off.

To start the assembly:
Figure 18.10: Dividing the sequence into three groups based on the number in the middle of the name.

Toolbox in the Menu Bar | Molecular Biology Tools | Sanger Sequencing Analysis | Add Sequences to Contig

or right-click in the empty white area of the contig | Add Sequences to Contig

This opens a dialog where you can select one contig and a number of sequences to assemble. If you have already selected sequences in the Navigation Area, these will be shown in the ‘Selected Elements’ box. However, you can remove these, or add others, by using the arrows to move sequences between the Navigation Area and Selected Elements boxes. You can also add sequence lists.

Often, the results of the assembly will be better if the sequences are trimmed first (see section 18.2.1).

When the elements are selected, click Next, and you will see the dialog shown in figure 18.11.

Figure 18.11: Setting assembly parameters when assembling to an existing contig.
The options in this dialog are similar to the options that are available when assembling to a reference sequence (see section 18.4).

Click Finish to start the tool. This will start the assembly process. See section 18.7 on how to use the resulting contig.

Note that the new sequences will be added to the existing contig which will not be extended. If the new sequences extend beyond the existing contig, they will be cut off.

### 18.7 View and edit contigs and read mappings

The results of the assembly or mapping (assembly to a reference) are respectively contigs or a read mapping. In both cases the sequence reads have been aligned (see figure 18.12). If multiple reference sequences were used, this information will be in a table where the actual visual mapping can be opened by double-clicking.

Figure 18.12: The view of a contig. Note that you can zoom to a very detailed level.

You can see that the color of the residues and trace at the end of one of the reads has been faded. This indicates that this region has not contributed to the contig or mapping. This may be due to trimming before or during the assembly or to misalignment to the other reads.

You can easily adjust the trimmed area to include more of the read in the contig or mapping: simply drag the edge of the faded area as shown in figure 18.13.

**Note!** The handles for dragging are only available at the zoom level where residues can be seen. This means that you need to have zoomed in to 100% or more and chosen Compactness levels "Not compact", "Low" or "Packed".

Residues are colored green unless they were reversed to map. In which case they will be red. The colors can be changed in the Side Panel as described in section 18.7.1.
If you find out that the reversed reads should have been the forward reads and vice versa, you can reverse complement the whole contig or mapping. Right-click in the empty white area of the contig or mapping and choose to **Reverse Complement Sequence**.

### 18.7.1 View settings in the Side Panel

The View Settings panel for assemblies and read mappings with fewer than 2000 reads resembles that of alignments (see section 20.2) but has some extra preferences described below (figure 18.14).

- **Read layout.** This section appears at the top of the Side Panel when viewing a stand-alone read mapping:
- **Compactness.** The compactness setting options let you control the level of detail to be displayed. This setting affects many of the other settings in the Side Panel as well as the general behavior of the view. For example: if the compactness is set to **Compact**, you will not be able to see quality scores or annotations on the reads, even if these are turned on via the "Nucleotide info" palette of the Side Panel. You can change the Compactness setting in the Side Panel directly, or you can use the shortcut: press and hold the Alt key while you scroll with the mouse wheel or touchpad.
  - **Not compact.** This allows the mapping to be viewed in full detail, including quality scores and trace data for the reads, where this is relevant. To view such information, additional viewing options under the Nucleotide info view settings must also selected. For further details on these, please see section 18.1.1 and section 11.1.
  - **Low.** Hides trace data, quality scores and puts the reads’ annotations on the sequence.
  - **Medium.** The labels of the reads and their annotations are hidden, and the residues of the reads cannot be seen.
  - **Compact.** Even less space between the reads.
  - **Packed.** All the other compactness settings will stack the reads on top of each other, but the packed setting will use all space available for displaying the reads. When zoomed in to 100%, you can see the residues but when zoomed out the reads will be represented as lines just as with the Compact setting. The packed mode is very useful when viewing large amounts of data. However certain functionality possible with other views are not available in packed view. For example, no editing of the read mapping or selections of it can be done and color coding changes are not possible.

- **Gather sequences at top.** Enabling this option affects the view that is shown when scrolling horizontally. If selected, the sequence reads which did not contribute to the visible part of the mapping will be omitted whereas the contributing sequence reads will automatically be placed right below the reference. This setting is not relevant when the compactness is packed.

- **Show sequence ends.** Regions that have been trimmed are shown with faded traces and residues. This illustrates that these regions have been ignored during the assembly.

- **Show mismatches.** When the compactness is packed, you can highlight mismatches which will get a color according to the Rasmol color scheme. A mismatch is whenever the base is different from the reference sequence at this position. This setting also causes the reads that have mismatches to be floated at the top of the view.

- **Disconnect pairs.** This option will break up the paired reads in the display (they are still marked as pairs - this just affects the visualization). The reads are marked with colors for the direction (default red and green) instead of the color for pairs (default blue). This is particularly useful when investigating overlapping pairs in packed view and when the strand / read orientation is important.

- **Packed read height.** When the compactness is set to "packed", you can choose the height of the visible reads. When there are more reads than the height specified, an overflow graph will be displayed below the reads. The overflow graph is shown in the same colors as the sequences, and mismatches in reads are shown as narrow vertical lines. The colors of the small lines represent the mismatching residue. The color
codes for the horizontal lines correspond to the color used for highlighting mismatches in the sequences (red = A, blue = C, yellow = G, and green = T), meaning that a red line with half the height of the blue part of the overflow graph will represent a mismatching "A" in half of the paired reads at this particular position.

- **Find Conflict.** Residues that are different from the reference are colored (as default), providing an overview of the conflicts. Clicking this button selects the next position where there is an conflict between the sequence reads. You can also use the Space key to find the next conflict.

- **Low coverage threshold.** All regions with coverage up to and including this value are considered low coverage. When clicking the 'Find low coverage' button the next region in the read mapping with low coverage will be selected.

- **Alignment info.** There is one additional parameter:
  - **Coverage:** Shows how many sequence reads that are contributing information to a given position in the mapping. The level of coverage is relative to the overall number of sequence reads.
    - *Foreground color.* Colors the letters using a gradient, where the left side color is used for low coverage and the right side is used for maximum coverage.
    - *Background color.* Colors the background of the letters using a gradient, where the left side color is used for low coverage and the right side is used for maximum coverage.
    - *Graph.* The coverage is displayed as a graph (Learn how to export the data behind the graph in section 6.8).
      - *Height.* Specifies the height of the graph.
      - *Type.* The graph can be displayed as Line plot, Bar plot or as a Color bar.
      - *Color box.* For Line and Bar plots, the color of the plot can be set by clicking the color box. If a Color bar is chosen, the color box is replaced by a gradient color box as described under Foreground color.

- **Residue coloring.** There is one additional parameter:
  - **Sequence colors.** This option lets you use different colors for the reads.
    - *Main.* The color of the consensus and reference sequence. Black per default.
    - *Forward.* The color of forward reads (single reads). Green per default.
    - *Paired.* The color of paired reads. Blue per default. Note that reads from broken pairs are colored according to their Forward/Reverse orientation or as a Non-specific match, but with a darker nuance than ordinary single reads.
    - *Non-specific matches.* When a read would have matched equally well another place in the mapping, it is considered a non-specific match. This color will "overrule" the other colors. Note that if you are mapping with several reference sequences, a read is considered a double match when it matches more than once across all the contigs/references. A non-specific match is yellow per default.

- **Sequence layout.**
  - **Matching residues as dots** Matching residues will be presented as dots. Only the top sequence will be preserved in its original format.
There are many other viewing options available, both general and aimed as specific elements of a contig or a mapping, which can be adjusted in the View settings. Those covered here were the key ones relevant for standard review of the results.

### 18.7.2 Editing a contig or read mapping

When editing contigs and read mappings, you are typically interested in confirming or changing single bases, and this can be done simply by:

- selecting the base  |  typing the right base

Some users prefer to use lower-case letters in order to be able to see which bases were altered when they use the results later on. In *CLC Genomics Workbench* all changes are recorded in the history log (see section 2.1.2), allowing the user to quickly reconstruct the actions performed in the editing session.

There are three shortcut keys for easily finding the positions where there are conflicts:

- Space bar: Finds the next conflict.
- "." (punctuation mark key): Finds the next conflict.
- "," (comma key): Finds the previous conflict.

In the contig or mapping view, you can use **Zoom in** to zoom to a greater level of detail than in other views (see figure 18.12). This is useful for discerning the trace curves.

If you want to replace a residue with a gap, use the **Delete** key.

If you wish to edit a selection of more than one residue:

- right-click the selection  |  Edit Selection

This will show a warning dialog, but you can choose never to see this dialog again by clicking the checkbox at the bottom of the dialog.

Note that for contigs or mappings with more than 1,000 reads, you can only do single-residue replacements (you can’t delete or edit a selection). When the compactness is **Packed**, you cannot edit any of the reads.

### 18.7.3 Sorting reads

If you wish to change the order of the sequence reads, simply drag the label of the sequence up and down. Note that this is not possible if you have chosen **Gather sequences at top** or set the compactness to **Packed** in the **Side Panel**.

You can also sort the reads by right-clicking a sequence label and choose from the following options:

- **Sort Reads by Alignment Start Position.** This will list the first read in the alignment at the top etc.
- **Sort Reads by Name.** Sort the reads alphabetically.
- **Sort Reads by Length.** The shortest reads will be listed at the top.
18.7.4 Read conflicts

After assembly or mapping, conflicts between the reads are annotated on the consensus sequence. The definition of a conflict is a position where at least one of the reads has a different residue compared to the reference.

A conflict can be in two states:

- **Conflict.** Both the annotation and the corresponding row in the Table are colored red.
- **Resolved.** Both the annotation and the corresponding row in the Table are colored green.

The conflict can be resolved by correcting the deviating residues in the reads as described above.

A fast way of making all the reads reflect the consensus sequence is to select the position in the consensus, right-click the selection, and choose Transfer Selection to All Reads.

The opposite is also possible: make a selection on one of the reads, right click, and Transfer Selection to Contig Sequence.

18.7.5 Using the mapping

Due to the integrated nature of CLC Genomics Workbench it is easy to use the consensus sequences as input for additional analyses. If you wish to extract the consensus sequence for further use, use the Extract Consensus Sequence tool (see section 25.6).

You can also right-click the consensus sequence and select Open Sequence. This will not create a new sequence but simply let you see the sequence in a sequence view. This means that the sequence still "belong" to the mapping and will be saved together with the mapping. It also means that if you add annotations to the sequence, they will be shown in the mapping view as well. This can be very convenient e.g. for Primer design.

If you wish to BLAST the consensus sequence, simply select the whole contig for your BLAST search. It will automatically extract the consensus sequence and perform the BLAST search.

In order to preserve the history of the changes you have made to the contig, the contig itself should be saved from the contig view, using either the save button or by dragging it to the Navigation Area.

18.7.6 Extract parts of a mapping

Sometimes it is useful to extract part of a mapping for in-depth analysis. This could be the case if you have performed an analysis of a whole genome data set and have found a region that you are particularly interested in analyzing further. Rather than running all further analysis on your full data, you may prefer to run only on a subset of the data. You can extract a subset of your mapping data by running the Extract from Selection tool on a selected region in your mapping. The result of running this tool is a new mapping which contains only the reads (and optionally only those that are of a particular type) in your selected region.

To select a region, use the Selection mode (see Section 2.2.3 for a detailed description of the different modes) and select you region of interest in your mapping, then right-click. You are now presented with the dialog shown in figure 18.15.
When you choose the **Extract from Selection** option you are presented by the dialog shown in figure 18.16.

The purpose of this dialog is to let you specify what kind of reads you want to include. Per default all reads are included. The options are:

**Paired status Include intact paired reads** When paired reads are placed within the paired distance specified, they will fall into this category. Per default, these reads are colored in blue.

**Include paired reads from broken pairs** When a pair is broken, either because only one read in the pair matches, or because the distance or relative orientation is wrong, the reads are placed and colored as single reads, but you can still extract them by checking this box.

**Include single reads** This will include reads that are marked as single reads (as opposed to paired reads). Note that paired reads that have been broken during assembly are not included in this category. Single reads that come from trimming paired sequence lists are included in this category.
CHAPTER 18. SEQUENCING DATA ANALYSES

**Match specificity** Include specific matches Reads that only are mapped to one position.

Include non-specific matches Reads that have multiple equally good alignments to the reference. These reads are colored yellow per default.

**Alignment quality** Include perfectly aligned reads Reads where the full read is perfectly aligned to the reference sequence (or consensus sequence for de novo assemblies). Note that at the end of the contig, reads may extend beyond the contig (this is not visible unless you make a selection on the read and observe the position numbering in the status bar). Such reads are not considered perfectly aligned reads because they don’t align in their entire length.

Include reads with less than perfect alignment Reads with mismatches, insertions or deletions, or with unaligned nucleotides at the ends (the faded part of a read).

**Spliced status** Include spliced reads Reads that are across an intron.

Include non spliced reads Reads that are not across an intron.

Note that only reads that are completely covered by the selection will be part of the new contig.

One of the benefits of this is that you can actually use this tool to extract subset of reads from a contig. An example work flow could look like this:

1. Select the whole reference sequence
2. Right-click and **Extract from Selection**
3. Choose to include only paired matches
4. Extract the reads from the new file (see section 14.2)

You will now have all paired reads from the original mapping in a list.

### 18.7.7 Variance table

In addition to the standard graphical display of a contig or mapping as described above, you can also see a tabular overview of the conflicts between the reads by clicking the **Table** icon at the bottom of the view.

This will display a new view of the conflicts as shown in figure 18.17.

The table has the following columns:

- **Reference position.** The position of the conflict measured from the starting point of the reference sequence.

- **Consensus position.** The position of the conflict measured from the starting point of the consensus sequence.

- **Consensus residue.** The consensus’s residue at this position. The residue can be edited in the graphical view, as described above.
Figure 18.17: The graphical view is displayed at the top, and underneath the conflicts are shown in a table. At the conflict at position 313, the user has entered a comment in the table (to see it, make sure the Notes column is wide enough to display all text lines). This comment is now also added to the tooltip of the conflict annotation in the graphical view above.

- **Other residues.** Lists the residues of the reads. Inside the brackets, you can see the number of reads having this residue at this position. In the example in figure 18.17, you can see that at position 637 there is a 'C' in the top read in the graphical view. The other two reads have a 'T'. Therefore, the table displays the following text: 'C (1), T (2)'.

- **IUPAC.** The ambiguity code for this position. The ambiguity code reflects the residues in the reads - not in the consensus sequence. (The IUPAC codes can be found in section G.)

- **Status.** The status can either be conflict or resolved:
  - **Conflict.** Initially, all the rows in the table have this status. This means that there is one or more differences between the sequences at this position.
  - **Resolved.** If you edit the sequences, e.g. if there was an error in one of the sequences, and they now all have the same residue at this position, the status is set to Resolved.

- **Note.** Can be used for your own comments on this conflict. Right-click in this cell of the table to add or edit the comments. The comments in the table are associated with the conflict annotation in the graphical view. Therefore, the comments you enter in the table will also be attached to the annotation on the consensus sequence (the comments can be displayed by placing the mouse cursor on the annotation for one second - see figure 18.17). The comments are saved when you Save ( ).

By clicking a row in the table, the corresponding position is highlighted in the graphical view. Clicking the rows of the table is another way of navigating the contig or the mapping, as are using the Find Conflict button or using the Space bar. You can use the up and down arrow keys to navigate the rows of the table.
18.8 Reassemble contig

If you have edited a contig, changed trimmed regions, or added or removed reads, you may wish to reassemble the contig. This can be done in two ways:

- **Toolbox | Molecular Biology Tools | Sanger Sequencing Analysis | Re-assemble Contig | select the contig from Navigation Area, move to 'Selected Elements' and click Next**

  or **right-click in the empty white area of the contig | Reassemble contig**

This opens a dialog as shown in figure 18.18

![Figure 18.18: Re-assembling a contig.](image)

In this dialog, you can choose:

- **De novo assembly.** This will perform a normal assembly in the same way as if you had selected the reads as individual sequences. When you click **Next**, you will follow the same steps as described in section 18.3. The consensus sequence of the contig will be ignored.

- **Reference assembly.** This will use the consensus sequence of the contig as reference. When you click **Next**, you will follow the same steps as described in section 18.4.

When you click **Finish**, a new contig is created, so you do not lose the information in the old contig.

18.9 Secondary peak calling

**CLC Genomics Workbench** is able to detect secondary peaks - a peak within a peak - to help discover heterozygous mutations. Looking at the height of the peak below the top peak, the **CLC Genomics Workbench** considers all positions in a sequence, and if a peak is higher than the threshold set by the user, it will be "called".

The peak detection investigates any secondary high peaks in the same interval as the already called peaks. The peaks must have a peak shape in order to be considered (i.e. a fading signal from the previous peak will be ignored). **Note!** The secondary peak caller does not call and annotate secondary peaks that have already been called by the Sanger sequencing machine and denoted with an ambiguity code.

Regions that are trimmed (i.e. covered by trim annotations) are ignored in the analysis (section 18.2).
When a secondary peak is called, the residue is change to an ambiguity character to reflect that two bases are possible at this position, and optionally an annotation is added at this position.

To call secondary peaks:

Toolbox | Molecular Biology Tools ( | Sanger Sequencing Analysis ( Call Secondary Peaks (This opens a dialog where you can add the sequences to be analyzed. If you had already selected sequence in the Navigation Area, these will be shown in the 'Selected Elements' box. However you can remove these, or add others, by using the arrows to move sequences between the Navigation Area and Selected Elements boxes.

When the sequences are selected, click Next.

This opens the dialog displayed in figure 18.19.

Figure 18.19: Setting parameters secondary peak calling.

The following parameters can be adjusted in the dialog:

- **Fraction of max peak height for calling.** Adjust this value to specify how high the secondary peak must be to be called.

- **Use IUPAC code / N for ambiguous nucleotides.** When a secondary peak is called, the residue at this position can either be replaced by an N or by a ambiguity character based on the IUPAC codes (see section G).

Clicking Next allows you to add annotations. In addition to changing the actual sequence, annotations can be added for each base that has been called. The annotations hold information about the fraction of the max peak height.

Click Finish to start the tool. This will start the secondary peak calling. A detailed history entry will be added to the history specifying all the changes made to the sequence.

CLC Genomics Workbench offers graphically advanced in silico cloning and design of vectors, together with restriction enzyme analysis and functionalities for managing lists of restriction enzymes.

19.1 Restriction site analyses

There are two ways of finding and showing restriction sites:

- In many cases, the dynamic restriction sites found in the Side Panel of sequence views is the fastest and easiest way of showing restriction sites.

- In the Toolbox you will find the Cloning and Restriction Sites tool that provides more control on the analysis, and gives you more output options such as a table of restriction sites. It also allows you to perform the same restriction map analysis on several sequences in one step.
19.1.1 Dynamic restriction sites

If you open a sequence, a sequence list etc, you will find a Restriction Sites section in the Side Panel.

Restriction sites can be shown on the sequence as colored triangles and lines (figure 19.1): check the "Show" option on top of the Restriction sites section, then specify the enzymes that should be displayed.

![Figure 19.1: Showing restriction sites of ten restriction enzymes.](image)

The color of the restriction enzyme can be changed by clicking the colored box next to the enzyme’s name. The name of the enzyme can also be shown next to the restriction site by selecting Show name flags above the list of restriction enzymes.

There is also an option to specify how the Labels shown be shown:

- **No labels.** This will just display the cut site with no information about the name of the enzyme. Placing the mouse button on the cut site will reveal this information as a tool tip.

- **Flag.** This will place a flag just above the sequence with the enzyme name (see an example in figure 19.2). Note that this option will make it hard to see when several cut sites are located close to each other. In the circular view, this option is replaced by the Radial option.

![Figure 19.2: Restriction site labels shown as flags.](image)
• **Radial.** This option is only available in the circular view. It will place the restriction site labels as close to the cut site as possible (see an example in figure 19.3).

![Figure 19.3: Restriction site labels in radial layout.](image)

• **Stacked.** This is similar to the flag option for linear sequence views, but it will stack the labels so that all enzymes are shown. For circular views, it will align all the labels on each side of the circle. This can be useful for clearly seeing the order of the cut sites when they are located closely together (see an example in figure 19.4).

![Figure 19.4: Restriction site labels stacked.](image)

Note that in a circular view, the **Stacked** and **Radial** options also affect the layout of annotations. Just above the list of enzymes, three buttons can be used for sorting the list (see figure 19.5).

![Figure 19.5: Buttons to sort restriction enzymes.](image)

• **Sort enzymes alphabetically (A).** Clicking this button will sort the list of enzymes alphabetically.

• **Sort enzymes by number of restriction sites (T).** This will divide the enzymes into four groups:
  - Non-cutters.
  - Single cutters.
  - Double cutters.
  - Multiple cutters.

There is a checkbox for each group which can be used to hide / show all the enzymes in a group.

• **Sort enzymes by overhang (L).** This will divide the enzymes into three groups:
  - Blunt. Enzymes cutting both strands at the same position.
  - 3’. Enzymes producing an overhang at the 3’ end.
– 5’. Enzymes producing an overhang at the 5’ end.

There is a checkbox for each group which can be used to hide / show all the enzymes in a group.

**Manage enzymes**

The list of restriction enzymes contains per default some of the most popular enzymes, but you can easily modify this list and add more enzymes by clicking the **Manage enzymes button** found at the bottom of the "Restriction sites" palette of the Side Panel.

This will open the dialog shown in figure 19.6.

![Figure 19.6: Adding or removing enzymes from the Side Panel.](image)

At the top, you can choose to **Use existing enzyme list**. Clicking this option lets you select an enzyme list which is stored in the **Navigation Area**. A list of popular enzymes is available in the Example Data folder you can download from the Help menu.

Below there are two panels:

- To the **left**, you can see all the enzymes that are in the list selected above. If you have not chosen to use a specific enzyme list, this panel shows all the enzymes available.

- To the **right**, you can see the list of the enzymes that will be used.

Select enzymes in the left side panel and add them to the right panel by double-clicking or clicking the **Add button**.

The enzymes can be sorted by clicking the column headings, i.e., Name, Overhang, Methylation or Popularity. This is particularly useful if you wish to use enzymes which produce a 3’ overhang for example.

When looking for a specific enzyme, it is easier to use the Filter. You can type HindIII or blunt into the filter, and the list of enzymes will shrink automatically to only include respectively only the HindIII enzyme, or all enzymes producing a blunt cut.
If you need more detailed information and filtering of the enzymes, you can hover your mouse on an enzyme (see figure 19.7). You can also open a view of an enzyme list saved in the Navigation Area.

![Figure 19.7: Showing additional information about an enzyme like recognition sequence or a list of commercial vendors.](image)

At the bottom of the dialog, you can select to save the updated list of enzymes as a new file. When you click Finish, the enzymes are added to the Side Panel and the cut sites are shown on the sequence. If you have specified a set of enzymes which you always use, it will probably be a good idea to save the settings in the Side Panel (see section 4.6) for future use.

**Show enzymes cutting inside/outside selection**

In cases where you have a selection on a sequence, and you wish to find enzymes cutting within the selection but not outside, right-click the selection and choose the option **Show Enzymes Cutting Inside/Outside Selection**. This will open a wizard where you can specify which enzymes should initially be considered (see section 19.1.1). You can for example select all the enzymes from a custom made list that correspond to all the enzymes that are already available in your lab.

In the following step (figure 19.8), you can define the terms of your search.

At the top of the dialog, you see the selected region, and below are two panels:

- **Inside selection.** Specify how many times you wish the enzyme to cut inside the selection.

- **Outside selection.** Specify how many times you wish the enzyme to cut outside the selection (i.e. the rest of the sequence).

These panels offer a lot of flexibility for combining number of cut sites inside and outside the selection, respectively. To give a hint of how many enzymes will be added based on the combination of cut sites, the preview panel at the bottom lists the enzymes which will be added when you click Finish. Note that this list is dynamically updated when you change the number of
cut sites. The enzymes shown in brackets \([\text{ ]}\) are enzymes which are already present in the Side Panel.

If you have selected more than one region on the sequence (using Ctrl or \[\text{ ]}\), they will be treated as individual regions. This means that the criteria for cut sites apply to each region.

**Show enzymes with compatible ends**

A third way of adding enzymes to the Side Panel and thereby displaying them on the sequence is based on the overhang produced by cutting with an enzyme. Right-click on a restriction site and choose to **Show Enzymes with Compatible Ends** (\[\text{ ]}\) to find enzymes producing a compatible overhang (figure 19.9).

At the top you can choose whether the enzymes considered should have an exact match or not. We recommend trying **Exact match** first, and use **All matches** as an alternative if a satisfactory
result cannot be achieved. Indeed, since a number of restriction enzymes have ambiguous cut patterns, there will be variations in the resulting overhangs. Choosing All matches, you cannot be 100% sure that the overhang will match, and you will need to inspect the sequence further afterwards.

Use the arrows between the two panels to select enzymes which will be displayed on the sequence and added to the Side Panel.

At the bottom of the dialog, the list of enzymes producing compatible overhangs is shown.

When you have added the relevant enzymes, click Finish, and the enzymes will be added to the Side Panel and their cut sites displayed on the sequence.

19.1.2 Restriction Site Analysis

Besides the dynamic restriction sites, you can do a more elaborate restriction map analysis with more output format using the Toolbox:

![Toolbox](image.png)

You first specify which sequence should be used for the analysis. Then define which enzymes to use as basis for finding restriction sites on the sequence (see section 19.1.1).

In the next dialog, you can use the checkboxes so that the output of the restriction map analysis only include restriction enzymes which cut the sequence a specific number of times (figure 19.10).

![Figure 19.10: Selecting number of cut sites.](image.png)

The default setting is to include the enzymes which cut the sequence one or two times, but you can use the checkboxes to perform very specific searches for restriction sites, for example to find enzymes which do not cut the sequence, or enzymes cutting exactly twice.

The Result handling dialog (figure 19.11) lets you specify how the result of the restriction map analysis should be presented.

Add restriction sites as annotations to sequence(s) . This option makes it possible to see the restriction sites on the sequence (see figure 19.12) and save the annotations for later use.
Create restriction map. When a restriction map is created, it can be shown in three different ways:

- As a table of restriction sites as shown in figure 19.13. If more than one sequence were selected, the table will include the restriction sites of all the sequences. This makes it easy to compare the result of the restriction map analysis for two sequences.

Each row in the table represents a restriction enzyme. The following information is available for each enzyme:

- **Sequence.** The name of the sequence which is relevant if you have performed restriction map analysis on more than one sequence.

- **Name.** The name of the enzyme.

- **Pattern.** The recognition sequence of the enzyme.

- **Length.** the restriction site length.

- **Overhang.** The overhang produced by cutting with the enzyme (3’, 5’ or Blunt).

- **Number of cut sites.**
Cut position(s). The position of each cut.

- [] If the enzyme’s recognition sequence is on the negative strand, the cut position is put in brackets.
- () Some enzymes cut the sequence twice for each recognition site, and in this case the two cut positions are surrounded by parentheses.

As a table of fragments which shows the sequence fragments that would be the result of cutting the sequence with the selected enzymes (see figure 19.14). Click the Fragments button at the bottom of the view.

Figure 19.14: The result of the restriction analysis shown as table of fragments.

Each row in the table represents a fragment. If more than one enzyme cuts in the same region, or if an enzyme’s recognition site is cut by another enzyme, there will be a fragment for each of the possible cut combinations. Furthermore, if this is the case, you will see the names of the other enzymes in the Conflicting Enzymes column.

The following information is available for each fragment.

- **Sequence.** The name of the sequence which is relevant if you have performed restriction map analysis on more than one sequence.
- **Length including overhang.** The length of the fragment. If there are overhangs of the fragment, these are included in the length (both 3’ and 5’ overhangs).
- **Region.** The fragment’s region on the original sequence.
- **Overhangs.** If there is an overhang, this is displayed with an abbreviated version of the fragment and its overhangs. The two rows of dots (.) represent the two strands of the fragment and the overhang is visualized on each side of the dots with the residue(s) that make up the overhang. If there are only the two rows of dots, it means that there is no overhang.
- **Left end.** The enzyme that cuts the fragment to the left (5’ end).
- **Right end.** The enzyme that cuts the fragment to the right (3’ end).
- **Conflicting enzymes.** If more than one enzyme cuts at the same position, or if an enzyme’s recognition site is cut by another enzyme, a fragment is displayed for each possible combination of cuts. At the same time, this column will display the enzymes that are in conflict. If there are conflicting enzymes, they will be colored red to alert the user. If the same experiment were performed in the lab, conflicting enzymes could lead to wrong results. For this reason, this functionality is useful to simulate digestions with complex combinations of restriction enzymes.

If views of both the fragment table and the sequence are open, clicking in the fragment table will select the corresponding region on the sequence.
• As a virtual gel simulation which shows the fragments as bands on a gel (see figure 19.40). For more information about gel electrophoresis, see section 19.5.

## 19.2 Restriction enzyme lists

**CLC Genomics Workbench** includes all the restriction enzymes available in the **REBASE** database, with methylation shown as performed by the cognate methylase rather than by Dam/Dcm. If you want to customize the enzyme database for your installation, see section D. However, when performing restriction site analyses, it is often an advantage to use a customized list of enzymes. In this case, the user can create special lists containing for example all enzymes available in the laboratory freezer, or all enzymes used to create a given restriction map or all enzymes that are available from the preferred vendor.

In the Example data (import in your Navigation Area using the Help menu), under Nucleotide->Restriction analysis, there are two enzyme lists: one with the 50 most popular enzymes, and another with all enzymes that are included in the **CLC Genomics Workbench**.

**Create enzyme list**  **CLC Genomics Workbench** uses enzymes from the **REBASE** restriction enzyme database at [http://rebase.neb.com](http://rebase.neb.com). If you want to customize the enzyme database for your installation, see section D.

To create an enzyme list of a subset of these enzymes:

- **File** | **New** | **Enzyme list**

This opens the dialog shown in figure 19.15

![Create new enzyme list](image)

*Figure 19.15: Choosing enzymes for the new enzyme list.*

Choose which enzyme you want to include in the new enzyme list (see section 19.1.1), and click **Finish** to open the enzyme list.

**View and modify enzyme list**  An enzyme list is shown in figure 19.16. It can be sorted by clicking the columns, and you can use the filter at the top right corner to search for specific
enzymes, recognition sequences etc.

If you wish to remove or add enzymes, click the Add/Remove Enzymes button at the bottom of the view. This will present the same dialog as shown in figure 19.15 with the enzyme list shown to the right.

If you wish to extract a subset of an enzyme list, open the list, select the relevant enzymes, right-click on the selection and choose to Create New Enzyme List from Selection.

If you combined this method with the filter located at the top of the view, you can extract a very specific set of enzymes. For example, if you wish to create a list of enzymes sold by a particular distributor, type the name of the distributor into the filter and select and create a new enzyme list from the selection.

19.3 Molecular cloning

The in silico cloning process in CLC Genomics Workbench begins with the Cloning tool:

Molecular Biology Tools | Cloning and Restriction Sites | Cloning

This will open a dialog where you can select both the sequences containing the fragments you want to clone, as well as the one to be used as vector (figure 19.17).

CLC Genomics Workbench will now create a sequence list of the selected fragments and vector sequences. For cloning work, open the sequence list and switch to the Cloning editor at the bottom of the view (figure 19.18).

If you later in the process need additional sequences, right-click anywhere on the empty white area of the view and choose to "Add Sequences".
19.3.1 Introduction to the cloning editor

In the cloning editor, most of the basic options for viewing, selecting and zooming the sequences are the same as for the standard sequence view (section 11.1). In particular, this means that annotations can be displayed on the sequences to guide the choice of regions to clone.

However, the cloning editor has a special layout with three distinct areas (in addition to the Side Panel found in other sequence views as well):

- At the top, there is a panel to switch between the sequences selected as input for the cloning. You can also specify whether the sequence should be visualized as circular or as a fragment. On the right-hand side, you can select a vector: the button is by default set to Change to Current. Click on it to select the currently shown sequence as vector.

- In the middle, the selected sequence is shown. This is the central area for defining how
The cloning should be performed.

- At the bottom, there is a panel where the selection of fragments and target vector is performed.

The cloning editor can be activated in different ways. One way is to click on the Cloning Editor icon in the view area when a sequence list has been opened in the sequence list editor. Another way is to create a new cloning experiment (the actual data object will still be a sequence list) using the Cloning action from the toolbox. Using this action the user collects a set of existing sequences and creates a new sequence list.

The cloning editor can be used in two different ways:

- **The cloning mode**, when the user has selected one of the sequences as 'Vector'. In the cloning mode, the user opens up the vector by applying one or more cuts to the vector, thereby creating an opening for insertion of other sequence fragments. From the remaining sequences in the cloning experiment/sequence list, either complete sequences or fragments created by cutting can be inserted into the vector. In the cloning adapter dialog, the user can switch the order of the inserted fragments and rotate them prior to adjusting the overhangs to match the cloning conditions.

- **The stitch mode**, when the user has not selected a sequence as 'Vector'. In stitch mode, the user can select a number of fragments (either full sequences or cuttings) from the cloning experiment. These fragments can then be stitched together into one single new and longer sequence. In the stitching adapter dialog, the user can switch order and rotate the fragments prior to adjusting the overhangs to match the stitch conditions.

### 19.3.2 The cloning workflow

The cloning workflow is designed to support restriction cloning workflows through the following steps:

1. **Define one or more fragments**
   
   First, select the sequence containing the cloning fragment in the list at the top of the view. Next, make sure the restriction enzyme you wish to use is listed in the Side Panel (see section 19.1.1). To specify which part of the sequence should be treated as the fragment, first click one of the cut sites you wish to use. Then press and hold the Ctrl key (⌘ on Mac) while you click the second cut site. You can also right-click the cut sites and use the Select This ... Site to select a site. If you just wish to remove the selection of one of the sites, right-click the site on the sequence and choose De-select This ... Site.

   When this is done, the panel is updated to reflect the selections (see figure 19.19).

   In this example you can see that there are now three fragments that can be used for cloning listed in the panel below the view. The fragment selected per default is the one that is in between the cut sites selected.

   If the entire sequence should be selected as fragment, click Add as Fragment.

   At any time, the selection of cut sites can be cleared by clicking the Remove icon to the right of the target vector selections.
2. Defining target vector

The next step is to define where the vector should be cut. If the vector sequence should just be opened, click the restriction site you want to use for opening (figure 19.20).

If you want to cut off part of the vector, click two restriction sites while pressing the Ctrl key.
You can also right-click the cut sites and use the Select This ... Site to select a site. This will display two options for what the target vector should be (for linear vectors there would have been three option). At any time, the selection of cut sites can be cleared by clicking the Remove (x) icon to the right of the target vector selections.

3. **Perform cloning**

Once both fragments and vector are selected, click Clone ( ). This will display a dialog to adapt overhangs and change orientation as shown in figure 19.21.

![Figure 19.21: Showing the insertion point of the vector.](image)

This dialog visualizes the details of the insertion. The vector sequence is on each side shown in a faded gray color. In the middle the fragment is displayed. If the overhangs of the sequence and the vector do not match ( ), you will not be able to click Finish. But you can blunt end or fill in the overhangs using the drag handles ( ) until the overhangs match ( ).

The fragment can be reverse complemented by clicking the Reverse complement fragment ( ).

When several fragments are used, the order of the fragments can be changed by clicking the move buttons ( )/ ( ).

Per default, the construct will be opened in a new view and can be saved separately. But selecting the option Replace input sequences with result will add the construct to the input sequence list and delete the original fragment and vector sequences.

Note that the cloning experiment used to design the construct can be saved as well. If you check the History ( ) of the construct, you can see the details about restriction sites and fragments used for the cloning.

### 19.3.3 Manual cloning

If you wish to use the manual way of cloning, you still create a sequence list with the Cloning tool, but can skip the "Perform cloning" step of the cloning workflow explained above in section 19.3.2. Instead, all manipulations of sequences are done manually, using right-click menus. These menus have two different appearances depending on where you click, as visualized in figure 19.22.

**Manipulate the whole sequence**

Right-click the sequence label to the left to see the menu shown in figure 19.23.
• **Duplicate sequence.** Adds a duplicate of the selected sequence to the sequence list accessible from the drop down menu on top of the Cloning view.

• **Insert sequence after this sequence ( ).** The sequence to be inserted can be selected from the sequence list via the drop down menu on top of the Cloning view. The inserted sequence remains on the list of sequences. If the two sequences do not have blunt ends, the ends’ overhangs have to match each other.

• **Insert sequence before this sequence ( ).** The sequence to be inserted can be selected from the sequence list via the drop down menu on top of the Cloning view. The inserted sequence remains on the list of sequences. If the two sequences do not have blunt ends, the ends’ overhangs have to match each other.

• **Reverse sequence.** Reverses the sequence and replaces the original sequence in the list. This is sometimes useful when working with single stranded sequences. Note that this is not the same as creating the reverse complement of a sequence.

• **Reverse complement sequence ( ).** Creates the reverse complement of a sequence and replaces the original sequence in the list. This is useful if the vector and the insert sequences are not oriented the same way.

• **Digest and Create Restriction Map ( ).** See section **19.5**

• **Rename sequence.** Renames the sequence.

• **Select sequence.** Selects the entire sequence.
• **Delete sequence** ([PNG]). Deletes the given sequence from the cloning editor.

• **Open sequence** ([PNG]). Opens the selected sequence in a normal sequence view.

• **Make sequence circular** ([PNG]). Converts a sequence from a linear to a circular form. If the sequence have matching overhangs at the ends, they will be merged together. If the sequence have incompatible overhangs, a dialog is displayed, and the sequence cannot be made circular. The circular form is represented by >> and << at the ends of the sequence.

• **Make sequence linear** ([PNG]). Converts a sequence from a circular to a linear form, removing the << and >> at the ends.

**Manipulate parts of the sequence**

Right-click on a selected region of the sequence to see the menu shown in figure 19.24.

![Figure 19.24: Right click on a sequence selection in the cloning view.](image)

• **Duplicate Selection.** If a selection on the sequence is duplicated, the selected region will be added as a new sequence to the cloning editor. The new sequence name representing the length of the fragment. When double-clicking on a sequence, the region between the two closest restriction sites is automatically selected.

• **Replace Selection with sequence.** Replaces the selected region with a sequence selected from the drop down menu listing all sequences in the cloning editor.

• **Cut Sequence Before Selection** ([PNG]). Cleaves the sequence before the selection and will result in two smaller fragments.

• **Cut Sequence After Selection** ([PNG]). Cleaves the sequence after the selection and will result in two smaller fragments.
• **Make Positive Strand Single Stranded** ((interval)). Makes the positive strand of the selected region single stranded.

• **Make Negative Strand Single Stranded** (interval). Makes the negative strand of the selected region single stranded.

• **Make Double Stranded** (interval). This will make the selected region double stranded.

• **Move Starting Point to Selection Start**. This is only active for circular sequences. It will move the starting point of the sequence to the beginning of the selection.

• **Copy** (interval). Copies the selected region to the clipboard, which will enable it for use in other programs.

• **Open Selection in New View** (interval). Opens the selected region in the normal sequence view.

• **Edit Selection** (interval). Opens a dialog box in which it is possible to edit the selected residues.

• **Delete Selection** (interval). Deletes the selected region of the sequence.

• **Add Annotation** (interval). Opens the Add annotation dialog box.

• **Insert Restriction Sites After/Before Selection**. Shows a dialog where you can choose from a list restriction enzymes (see section 19.3.4).

• **Show Enzymes Cutting Inside/Outside Selection** (interval). Adds enzymes cutting this selection to the Side Panel.

• **Add Structure Prediction Constraints**. This is relevant for RNA secondary structure prediction:
  
  – **Force Stem Here** is activated after choosing 2 regions of equal length on the sequence. It will add an annotation labeled "Forced Stem" and will force the algorithm to compute minimum free energy and structure with a stem in the selected region.

  – **Prohibit Stem Here** is activated after choosing 2 regions of equal length on the sequence. It will add an annotation labeled "Prohibited Stem" to the sequence and will force the algorithm to compute minimum free energy and structure without a stem in the selected region.

  – **Prohibit From Forming Base Pairs** will add an annotation labeled "No base pairs" to the sequence, and will force the algorithm to compute minimum free energy and structure without a base pair containing any residues in the selected region.

**Insert one sequence into another**

Sequences can be inserted into each other in various ways as described in the lists above. When you choose to insert one sequence into another, you will be presented with a dialog where all sequences in the sequence list are present (see figure 19.25).

The sequence that you have chosen to insert into will be marked with **bold** and the text [vector] is appended to the sequence name. Note that this is completely unrelated to the vector concept in the cloning workflow described in section 19.3.2.

Furthermore, the list includes the length of the fragment, an indication of the overhangs, and a list of enzymes that are compatible with this overhang (for the left and right ends, respectively).
If not all the enzymes can be shown, place your mouse cursor on the enzymes, and a full list will be shown in the tool tip.

Select the sequence you wish to insert and click **Next** to adapt insert sequence to vector dialog (figure 19.26).

At the top is a button to reverse complement the inserted sequence.

Below is a visualization of the insertion details. The inserted sequence is at the middle shown in red, and the vector has been split at the insertion point and the ends are shown at each side of the inserted sequence.

If the overhangs of the sequence and the vector do not match (≠), you can blunt end or fill in the overhangs using the **drag handles** (↑) until it does (✔).

At the bottom of the dialog is a summary field which records all the changes made to the overhangs. This contents of the summary will also be written in the history (◼) of the cloning experiment.

When you click **Finish**, the sequence is inserted and highlighted by being selected.
CHAPTER 19. CUTTING AND CLONING

Figure 19.27: One sequence is now inserted into the cloning vector. The sequence inserted is automatically selected.

19.3.4 Insert restriction site

If you right-click on a selected region of a sequence, you find this option for inserting the recognition sequence of a restriction enzyme before or after the region you selected. This will display a dialog as shown in figure 19.28

Figure 19.28: Inserting a restriction site and potentially a recognition sequence.

At the top, you can select an existing enzyme list or you can use the full list of enzymes (default). Select an enzyme, and you will see its recognition sequence in the text field below the list (AAGCTT). If you wish to insert additional residues such as tags, this can be typed into the text fields adjacent to the recognition sequence.

Click OK will insert the restriction site and the tag(s) before or after the selection. If the enzyme selected was not already present in the list in the Side Panel, it will now be added and selected.

19.4 Gateway cloning

CLC Genomics Workbench offers tools to perform in silico Gateway cloning\(^1\), including Multi-site Gateway cloning.

The three tools for doing Gateway cloning in the CLC Genomics Workbench mimic the procedure

---

\(^1\)Gateway is a registered trademark of Invitrogen Corporation
followed in the lab:

- First, attB sites are added to a sequence fragment
- Second, the attB-flanked fragment is recombined into a donor vector (the BP reaction) to construct an entry clone
- Finally, the target fragment from the entry clone is recombined into an expression vector (the LR reaction) to construct an expression clone. For Multi-site gateway cloning, multiple entry clones can be created that can recombine in the LR reaction.

During this process, both the attB-flanked fragment and the entry clone can be saved.

For more information about the Gateway technology, please visit [http://www.thermofisher.com/us/en/home/life-science/cloning/gateway-cloning/gateway-technology.html](http://www.thermofisher.com/us/en/home/life-science/cloning/gateway-cloning/gateway-technology.html). To perform these analyses in CLC Genomics Workbench, you need to import donor and expression vectors. These can be found on the Thermo Fisher Scientific’s website: find the relevant vector sequences, copy them, and paste them in the field that opens when you choose New | Sequence in the workbench. Fill in additional information appropriately (enter a "Name", check the "Circular" option) and save the sequences in the Navigation Area.

### 19.4.1 Add attB sites

The first step in the Gateway cloning process is to amplify the target sequence with primers including so-called attB sites:

![Toolbox](image) | Molecular Biology Tools (️) | Cloning and Restriction Sites (️) | Gateway Cloning (️) | Add attB Sites (️)

This will open a dialog where you can select one or more sequences. Note that if your fragment is part of a longer sequence, you will need to extract it prior to starting the tool: select the relevant region (or an annotation) of the original sequence, right-click the selection and choose to Open Annotation in New View. Save (️) the new sequence in the Navigation Area.

When you have selected your fragment(s), click Next.

This will allow you to choose which attB sites you wish to add to each end of the fragment as shown in figure 19.29.

![Figure 19.29: Selecting which attB sites to add.](image)

The default option is to use the attB1 and attB2 sites. If you have selected several fragments and wish to add different combinations of sites, you will have to run this tool once for each combination.
Next, you are given the option to extend the fragment with additional sequences by extending the primers 5’ of the template-specific part of the primer, i.e., between the template specific part and the attB sites.

You can manually type or paste in a sequence of your choice, but it is also possible to click in the text field and press Shift + F1 (Shift + Fn + F1 on Mac) to show some of the most common additions (see figure 19.30). Use the up and down arrow keys to select a tag and press Enter. To learn how to modify the default list of primer additions, see section 19.4.1.

![Figure 19.30: Primer additions 5’ of the template-specific part of the primer where a Shine-Dalgarno site has been added between the attB site and the gene of interest.](image)

At the bottom of the dialog, you can see a preview of what the final PCR product will look like. In the middle there is the sequence of interest. In the beginning is the attB1 site, and at the end is the attB2 site. The primer additions that you have inserted are shown in colors.

In the next step, specify the length of the template-specific part of the primers as shown in figure 19.31.

![Figure 19.31: Specifying the length of the template-specific part of the primers.](image)

*CLC Genomics Workbench* is not doing any kind of primer design when adding the attB sites. As a user, you simply specify the length of the template-specific part of the primer, and together with the attB sites and optional primer additions, this will be the primer. The primer region will be annotated in the resulting attB-flanked sequence. You can also choose to get a list of primers in the Result handling dialog (see figure 19.32).

The attB sites, the primer additions and the primer regions are annotated in the final result as shown in figure 19.33 (you may need to switch on the relevant annotation types to show the
Figure 19.32: Besides the main output which is a copy of the input sequence(s) now including attB sites and primer additions, you can get a list of primers as output.

There will be one output sequence for each sequence you have selected for adding attB sites. Save the resulting sequence as it will be the input to the next part of the Gateway cloning workflow (see section 19.4.2).

Extending the pre-defined list of primer additions

The list of primer additions shown when pressing Shift+F1 (on Mac: Shift + fn + F1) in the dialog shown in figure 19.30 can be configured and extended. If there is a tag that you use a lot, you can add it to the list for convenient and easy access later on. This is done in the Preferences:

   Edit | Preferences | Data

In the table Multisite Gateway Cloning primer additions (see figure 19.34), select which primer addition options you want to add to forward or reverse primers. You can edit the existing elements in the table by double-clicking any of the cells, or you can use the buttons below to Add Row or Delete Row. If you by accident have deleted or modified some of the default primer additions, you can press Add Default Rows. Note that this will not reset the table but only add all the default rows to the existing rows.

Each element in the list has the following information:

Name When the sequence fragment is extended with a primer addition, an annotation will be added displaying this name.

Sequence The actual sequence to be inserted, defined on the sense strand (although the reverse primer would be reverse complement).
19.4.2 Create entry clones (BP)

The next step in the Gateway cloning workflow is to recombine the attB-flanked sequence of interest into a donor vector to create an entry clone. Before proceeding to this step, make sure that the sequence of the destination vector was saved in the Navigation Area: find the relevant vector sequence on the Thermo Fisher Scientific’s website, copy it, and paste it in the field that opens when you choose New | Sequence in the workbench. Fill in additional information appropriately (enter a "Name", check the "Circular" option) and save the sequence in the Navigation Area.

In the first wizard window, select one or more sequences to be recombined into your donor vector. Note that the sequences you select should be flanked with attB sites (see section 19.4.1). You can select more than one sequence as input, and the corresponding number of entry clones will be created.

In the following dialog (figure 19.35), you can specify a donor vector. Once the vector is selected, a preview of the fragments selected and the attB sites that they contain is shown. This can be used to get an overview of which entry clones should be used and check that the right attB sites have been added to the fragments. Also note that the workbench looks for the attP sites (see how to change the definition of sites in appendix E), but it does not
check that they correspond to the attB sites of the selected fragments at this step. If the right combination of attB and attP sites is not found, no entry clones will be produced.

The output is one entry clone per sequence selected. The attB and attP sites have been used for the recombination, and the entry clone is now equipped with attL sites as shown in figure 19.36.

Note that the bi-product of the recombination is not part of the output.

**19.4.3 Create expression clones (LR)**

The final step in the Gateway cloning work flow is to recombine the entry clone into a destination vector to create an expression clone. Before proceeding to this step, make sure that the sequence of the destination vector was saved in the Navigation Area: find the relevant vector sequence on the Thermo Fisher Scientific’s website, copy it, and paste it in in the field that opens when you choose New | Sequence in the workbench. Fill in additional information appropriately (enter a “Name”, check the “Circular” option) and save the sequence in the Navigation Area.

Note also that for a destination vector to be recognized, it must contain appropriate att sites and the ccdB gene. This gene must be present either as a ‘ccdB’ annotation, or as the exact sequence:

```
ATGCAGTTTAAGGTTTACACCTATAAAAGAGAGAGCCGTTATCGTCTGTTTGTGGATGTACAGAGTGATATT
ATTGACACGCCCGGGCGACGGATGGTGATCCCCCTGGCCAGTGCACGTCTGCTGTCAGATAAAGTCTCC
CTTGAACTTTACCCGGTGCGATATCGGGGATGAAAGCTGGCGCATGATGACCACCGATATGGCCAGT
GTGCCGGTCTCCGTTATCGGGAAAAGATGCGCTGATCTCTCAACGCCAMGAAATTGACATCAAAACG
```
If the ccdB gene is not present or if the sequence is not identical to the above, a solution is to simply add a ‘ccdB’ annotation. Select part of the vector sequence, right-click and choose ‘Add Annotation’. Name the annotation ‘ccdB’.

You can now start the tool:

In the first step, select one or more entry clones (see how to create an entry clone in section 19.4.2). If you wish to perform separate LR reactions with multiple entry clones, you should run the Create Expression Clone in batch mode (see section 9.3).

In the second step, select the destination vector that was previously saved in the Navigation Area (fig 19.37).

Figure 19.37: Selecting one or more destination vectors.

Note that the workbench looks for the specific sequences of the attR sites in the sequences that you select in this dialog (see how to change the definition of sites in appendix E), but it does not check that they correspond to the attL sites of the selected fragments. If the right combination of attL and attR sites is not found, no entry clones will be produced.

When performing multi-site gateway cloning, CLC Genomics Workbench will insert the fragments (contained in entry clones) by matching the sites that are compatible. If the sites have been defined correctly, an expression clone containing all the fragments will be created. You can find an explanation of the multi-site gateway system at https://www.thermofisher.com/dk/en/home/life-science/cloning/gateway-cloning/multisite-gateway-technology.html?SID=fr-gwcloning-3

The output is a number of expression clones depending on how many entry clones and destination vectors that you selected. The attL and attR sites have been used for the recombination, and the expression clone is now equipped with attB sites as shown in figure 19.38.

You can choose to create a sequence list with the bi-products as well.

19.5 Gel electrophoresis

CLC Genomics Workbench enables the user to simulate the separation of nucleotide sequences on a gel. This feature is useful when designing an experiment which will allow the differentiation of a successful and an unsuccessful cloning experiment on the basis of a restriction map.

There are several ways to simulate gel separation of nucleotide sequences:

- When performing the Restriction Site Analysis from the Toolbox, you can choose to create
CHAPTER 19. CUTTING AND CLONING

Figure 19.38: The resulting expression clone opened in a circular view.

a restriction map which can be shown as a gel (see section 19.1.2).

- From all the graphical views of sequences, you can right-click the name of the sequence and choose *Digest and Create Restriction Map* ( ). The sequence will be digested with the enzymes that are selected in the Side Panel. The views where this option is available are listed below:
  - Circular view (see section 11.2).
  - Ordinary sequence view (see section 11.1).
  - Graphical view of sequence lists (see section 11.6).
  - Cloning editor (see section 19.3).
  - Primer designer (see section 17.3).

- **Separate sequences on gel**: To separate sequences without restriction enzyme digestion, first create a sequence list of the sequences in question, then click the *Gel* button ( ) at the bottom of the view of the sequence list (figure 19.39).

19.5.1 Gel view

In figure 19.40 you can see a simulation of a gel with its Side Panel to the right.

**Information on bands / fragments**: You can get information about the individual bands by hovering the mouse cursor on the band of interest. This will display a tool tip with the following information:

- Fragment length
- Fragment region on the original sequence
- Enzymes cutting at the left and right ends, respectively

For gels comparing whole sequences, you will see the sequence name and the length of the sequence.
Note! You have to be in Selection ( _) or Pan ( _) mode in order to get this information.

It can be useful to add markers to the gel which enables you to compare the sizes of the bands. This is done by clicking Show marker ladder in the Side Panel.

Markers can be entered into the text field, separated by commas.

Modifying the layout  The background of the lane and the colors of the bands can be changed in the Side Panel. Click the colored box to display a dialog for picking a color. The slider Scale band spread can be used to adjust the effective time of separation on the gel, i.e. how much
the bands will be spread over the lane. In a real electrophoresis experiment this property will be
determined by several factors including time of separation, voltage and gel density.

You can also choose how many lanes should be displayed:

- **Sequences in separate lanes.** This simulates that a gel is run for each sequence.
- **All sequences in one lane.** This simulates that one gel is run for all sequences.

You can also modify the layout of the view by zooming in or out. Click **Zoom in (Zoom in)** or **Zoom out (Zoom out)** in the Toolbar and click the view.

Finally, you can modify the format of the text heading each lane in the Text format preferences in the Side Panel.

CLC Genomics Workbench can align nucleotides and proteins using a progressive alignment algorithm (see section 20.5.2).

This chapter describes how to use the program to align sequences, and alignment algorithms in more general terms.

20.1 Create an alignment

Alignments can be created from sequences, sequence lists (see section 11.6), existing alignments and from any combination of the three.

To create an alignment in CLC Genomics Workbench:

   Toolbox | Classical Sequence Analysis ( ) | Alignments and Trees ( ) | Create Alignment ( )

This opens the dialog shown in figure 20.1.
Figure 20.1: Creating an alignment.

If you have selected some elements before choosing the Toolbox action, they are now listed in the Selected Elements window of the dialog. Use the arrows to add or remove sequences, sequence lists or alignments from the selected elements. Click Next to adjust alignment algorithm parameters. Clicking Next opens the dialog shown in figure 20.2.

Figure 20.2: Adjusting alignment algorithm parameters.

20.1.1 Gap costs

The alignment algorithm has three parameters concerning gap costs: Gap open cost, Gap extension cost and End gap cost. The precision of these parameters is to one place of decimal.

- **Gap open cost.** The price for introducing gaps in an alignment.

- **Gap extension cost.** The price for every extension past the initial gap.

If you expect a lot of small gaps in your alignment, the Gap open cost should equal the Gap extension cost. On the other hand, if you expect few but large gaps, the Gap open cost should be set significantly higher than the Gap extension cost.

However, for most alignments it is a good idea to make the Gap open cost quite a bit higher than the Gap extension cost. The default values are 10.0 and 1.0 for the two parameters, respectively.
• **End gap cost.** The price of gaps at the beginning or the end of the alignment. One of the advantages of the CLC Genomics Workbench alignment method is that it provides flexibility in the treatment of gaps at the ends of the sequences. There are three possibilities:

  - **Free end gaps.** Any number of gaps can be inserted in the ends of the sequences without any cost.
  - **Cheap end gaps.** All end gaps are treated as gap extensions and any gaps past 10 are free.
  - **End gaps as any other.** Gaps at the ends of sequences are treated like gaps in any other place in the sequences.

When aligning a long sequence with a short partial sequence, it is ideal to use free end gaps, since this will be the best approximation to the situation. The many gaps inserted at the ends are not due to evolutionary events, but rather to partial data.

Many homologous proteins have quite different ends, often with large insertions or deletions. This confuses alignment algorithms, but using the **Cheap end gaps** option, large gaps will generally be tolerated at the sequence ends, improving the overall alignment. This is the default setting of the algorithm.

Finally, treating end gaps like any other gaps is the best option when you know that there are no biologically distinct effects at the ends of the sequences.

Figures 20.3 and 20.4 illustrate the differences between the different gap scores at the sequence ends.

![Figure 20.3](image1.png)

**Figure 20.3:** The first 50 positions of two different alignments of seven calpastatin sequences. The top alignment is made with cheap end gaps, while the bottom alignment is made with end gaps having the same price as any other gaps. In this case it seems that the latter scoring scheme gives the best result.

### 20.1.2 Fast or accurate alignment algorithm

CLC Genomics Workbench has two algorithms for calculating alignments:

- **Fast (less accurate).** This allows for use of an optimized alignment algorithm which is very fast. The fast option is particularly useful for data sets with very long sequences.

- **Slow (very accurate).** This is the recommended choice unless you find the processing time too long.
CHAPTER 20. SEQUENCE ALIGNMENT

Figure 20.4: The alignment of the coding sequence of bovine myoglobin with the full mRNA of human gamma globin. The top alignment is made with free end gaps, while the bottom alignment is made with end gaps treated as any other. The yellow annotation is the coding sequence in both sequences. It is evident that free end gaps are ideal in this situation as the start codons are aligned correctly in the top alignment. Treating end gaps as any other gaps in the case of aligning distant homologs where one sequence is partial leads to a spreading out of the short sequence as in the bottom alignment.

Both algorithms use progressive alignment. The faster algorithm builds the initial tree by doing more approximate pairwise alignments than the slower option.

20.1.3 Aligning alignments

If you have selected an existing alignment in the first step (20.1), you have to decide how this alignment should be treated.

- **Redo alignment.** The original alignment will be realigned if this checkbox is checked. Otherwise, the original alignment is kept in its original form except for possible extra equally sized gaps in all sequences of the original alignment. This is visualized in figure 20.5.

This feature is useful if you wish to add extra sequences to an existing alignment, in which case you just select the alignment and the extra sequences and choose not to redo the alignment.

It is also useful if you have created an alignment where the gaps are not placed correctly. In this case, you can realign the alignment with different gap cost parameters.

20.1.4 Fixpoints

With fixpoints, you can get full control over the alignment algorithm. The fixpoints are points on the sequences that are forced to align to each other.

To add a fixpoint, open the sequence or alignment and:

- Select the region you want to use as a fixpoint | right-click the selection | Set alignment fixpoint here
Figure 20.5: The top figures shows the original alignment. In the bottom panel a single sequence with four inserted X’s are aligned to the original alignment. This introduces gaps in all sequences of the original alignment. All other positions in the original alignment are fixed.

This will add an annotation labeled “Fixpoint” to the sequence (see figure 20.6). Use this procedure to add fixpoints to the other sequence(s) that should be forced to align to each other.

Figure 20.6: Adding a fixpoint to a sequence in an existing alignment. At the top you can see a fixpoint that has already been added.

When you click “Create alignment” and go to Step 2, check Use fixpoints in order to force the alignment algorithm to align the fixpoints in the selected sequences to each other.

In figure 20.7 the result of an alignment using fixpoints is illustrated.
CHAPTER 20. SEQUENCE ALIGNMENT 462

Figure 20.7: Realigning using fixpoints. In the top view, fixpoints have been added to two of the sequences. In the view below, the alignment has been realigned using the fixpoints. The three top sequences are very similar, and therefore they follow the one sequence (number two from the top) that has a fixpoint.

You can add multiple fixpoints, e.g. adding two fixpoints to the sequences that are aligned will force their first fixpoints to be aligned to each other, and their second fixpoints will also be aligned to each other.

**Advanced use of fixpoints** Fixpoints with the same names will be aligned to each other, which gives the opportunity for great control over the alignment process. It is only necessary to change any fixpoint names in very special cases.

One example would be three sequences A, B and C where sequences A and B has one copy of a domain while sequence C has two copies of the domain. You can now force sequence A to align to the first copy and sequence B to align to the second copy of the domains in sequence C. This is done by inserting fixpoints in sequence C for each domain, and naming them ‘fp1’ and ‘fp2’ (for example). Now, you can insert a fixpoint in each of sequences A and B, naming them ‘fp1’ and ‘fp2’, respectively. Now, when aligning the three sequences using fixpoints, sequence A will align to the first copy of the domain in sequence C, while sequence B would align to the second copy of the domain in sequence C.

You can name fixpoints by:

```
right-click the Fixpoint annotation | Edit Annotation (_bag) | type the name in the 'Name' field
```

20.2 View alignments

Since an alignment is a display of several sequences arranged in rows, the basic options for viewing alignments are the same as for viewing sequences. Therefore we refer to section 11.1 for an explanation of these basic options.

However, there are a number of alignment-specific view options in the Alignment info and the Nucleotide info.
in the Side Panel to the right of the view. Below is more information on these view options.

Under Translation in the Nucleotide info, there is an extra checkbox: Relative to top sequence. Checking this box will make the reading frames for the translation align with the top sequence so that you can compare the effect of nucleotide differences on the protein level.

The options in the Alignment info relate to each column in the alignment.

Consensus Shows a consensus sequence at the bottom of the alignment. The consensus sequence is based on every single position in the alignment and reflects an artificial sequence which resembles the sequence information of the alignment, but only as one single sequence. If all sequences of the alignment is 100% identical the consensus sequence will be identical to all sequences found in the alignment. If the sequences of the alignment differ the consensus sequence will reflect the most common sequences in the alignment. Parameters for adjusting the consensus sequences are described below.

- **Limit** This option determines how conserved the sequences must be in order to agree on a consensus. Here you can also choose IUPAC which will display the ambiguity code when there are differences between the sequences. For example, an alignment with A and a G at the same position will display an R in the consensus line if the IUPAC option is selected. The IUPAC codes can be found in section G and F. Please note that the IUPAC codes are only available for nucleotide alignments.

- **No gaps** Checking this option will not show gaps in the consensus.

- **Ambiguous symbol** Select how ambiguities should be displayed in the consensus line (as N, ?, *, . or -). This option has no effect if IUPAC is selected in the Limit list above.

The Consensus Sequence can be opened in a new view, simply by right-clicking the Consensus Sequence and click Open Consensus in New View.

Conservation Displays the level of conservation at each position in the alignment. The conservation shows the conservation of all sequence positions. The height of the bar, or the gradient of the color reflect how conserved that particular position is in the alignment. If one position is 100% conserved the bar will be shown in full height, and it is colored in the color specified at the right side of the gradient slider.

- **Foreground color** Colors the letters using a gradient, where the right side color is used for highly conserved positions and the left side color is used for positions that are less conserved.

- **Background color**. Sets a background color of the residues using a gradient in the same way as described above.

- **Graph** Displays the conservation level as a graph at the bottom of the alignment. The bar (default view) show the conservation of all sequence positions. The height of the graph reflects how conserved that particular position is in the alignment. If one position is 100% conserved the graph will be shown in full height. Learn how to export the data behind the graph in section 6.8.
Gap fraction Which fraction of the sequences in the alignment that have gaps. The gap fraction is only relevant if there are gaps in the alignment.

- **Foreground color** Colors the letter using a gradient, where the left side color is used if there are relatively few gaps, and the right side color is used if there are relatively many gaps.
- **Background color** Sets a background color of the residues using a gradient in the same way as described above.
- **Graph** Displays the gap fraction as a graph at the bottom of the alignment (Learn how to export the data behind the graph in section 6.8).

Color different residues Indicates differences in aligned residues.

- **Foreground color** Colors the letter.
- **Background color.** Sets a background color of the residues.

Sequence logo A sequence logo displays the frequencies of residues at each position in an alignment. This is presented as the relative heights of letters, along with the degree of sequence conservation as the total height of a stack of letters, measured in bits of information. The vertical scale is in bits, with a maximum of 2 bits for nucleotides and approximately 4.32 bits for amino acid residues. See section 20.2.1 for more details.

- **Foreground color** Color the residues using a gradient according to the information content of the alignment column. Low values indicate columns with high variability whereas high values indicate columns with similar residues.
- **Background color** Sets a background color of the residues using a gradient in the same way as described above.
- **Logo** Displays sequence logo at the bottom of the alignment.

- **Height** Specifies the height of the sequence logo graph.
- **Color** The sequence logo can be displayed in black or Rasmol colors. For protein alignments, a polarity color scheme is also available, where hydrophobic residues are shown in black color, hydrophilic residues as green, acidic residues as red and basic residues as blue.
20.2.1 Bioinformatics explained: Sequence logo

In the search for homologous sequences, researchers are often interested in conserved sites/residues or positions in a sequence which tend to differ a lot. Most researches use alignments (see Bioinformatics explained: multiple alignments) for visualization of homology on a given set of either DNA or protein sequences. In proteins, active sites in a given protein family are often highly conserved. Thus, in an alignment these positions (which are not necessarily located in proximity) are fully or nearly fully conserved. On the other hand, antigen binding sites in the F\textsubscript{ab} unit of immunoglobulins tend to differ quite a lot, whereas the rest of the protein remains relatively unchanged.

In DNA, promoter sites or other DNA binding sites are highly conserved (see figure 20.8). This is also the case for repressor sites as seen for the Cro repressor of bacteriophage \(\lambda\).

When aligning such sequences, regardless of whether they are highly variable or highly conserved at specific sites, it is very difficult to generate a consensus sequence which covers the actual variability of a given position. In order to better understand the information content or significance of certain positions, a sequence logo can be used. The sequence logo displays the information content of all positions in an alignment as residues or nucleotides stacked on top of each other (see figure 20.8). The sequence logo provides a far more detailed view of the entire alignment than a simple consensus sequence. Sequence logos can aid to identify protein binding sites on DNA sequences and can also aid to identify conserved residues in aligned domains of protein sequences and a wide range of other applications.

Each position of the alignment and consequently the sequence logo shows the sequence information in a computed score based on Shannon entropy [Schneider and Stephens, 1990]. The height of the individual letters represent the sequence information content in that particular position of the alignment.

A sequence logo is a much better visualization tool than a simple consensus sequence. An example hereof is an alignment where in one position a particular residue is found in 70% of the sequences. If a consensus sequence is used, it typically only displays the single residue with 70% coverage. In figure 20.8 an un-gapped alignment of 11 \(E. coli\) start codons including flanking regions are shown. In this example, a consensus sequence would only display ATG as the start codon, but when looking at the sequence logo it is seen that a GTG is also allowed as a start codon.

**Calculation of sequence logos** A comprehensive walk-through of the calculation of the information content in sequence logos is beyond the scope of this document but can be found in the original paper by [Schneider and Stephens, 1990]. Nevertheless, the conservation of every position is defined as \(R_{seq}\) which is the difference between the maximal entropy \(S_{max}\) and the observed entropy for the residue distribution \(S_{obs}\),

\[
R_{seq} = S_{max} - S_{obs} = \log_2 N - \left( -\sum_{n=1}^{N} p_n \log_2 p_n \right)
\]

\(p_n\) is the observed frequency of a amino acid residue or nucleotide of symbol \(n\) at a particular position and \(N\) is the number of distinct symbols for the sequence alphabet, either 20 for proteins or four for DNA/RNA. This means that the maximal sequence information content per position is \(\log_2 4 = 2\) bits for DNA/RNA and \(\log_2 20 \approx 4.32\) bits for proteins.
 hated
Note! Residues can only be moved when they are next to a gap.

\[

\text{AGG GACTCAT} \\
\text{AGG GAGCAGT} \\
\ldots \\
\text{AGG GTACAGT} \\
\text{- - - GACTAGC - ACG - - TAGC} \\
\text{- - - GACTAGC - ATC - - TAGC} \\
\text{- - - GACTAGG - ACG - - TAGG} \\
\text{ATG GTGCACC} \\
\text{ATG GTGCATC}
\end{array}
\]

Figure 20.9: Moving a part of an alignment. Notice the change of mouse pointer to a horizontal arrow.

**Insert gaps** The placement of gaps in the alignment can be changed by modifying the parameters when creating the alignment. However, gaps can also be added manually after the alignment is created.

To insert extra gaps:

- select a part of the alignment
- right-click the selection
- Add gaps before/after

If you have made a selection covering five residues for example, a gap of five will be inserted. In this way you can easily control the number of gaps to insert. Gaps will be inserted in the sequences that you selected. If you make a selection in two sequences in an alignment, gaps will be inserted into these two sequences. This means that these two sequences will be displaced compared to the other sequences in the alignment.

**Delete residues and gaps** Residues or gaps can be deleted for individual sequences or for the whole alignment. For individual sequences:

- select the part of the sequence you want to delete
- right-click the selection
- Edit Selection
- Delete the text in the dialog
- Replace

The selection shown in the dialog will be replaced by the text you enter. If you delete the text, the selection will be replaced by an empty text, i.e. deleted.

In order to delete entire columns:

- manually select the columns to delete
- right-click the selection
- click 'Delete Selection'

**Copy annotations to other sequences** Annotations on one sequence can be transferred to other sequences in the alignment:

- right-click the annotation
- Copy Annotation to other Sequences

This will display a dialog listing all the sequences in the alignment. Next to each sequence is a checkbox which is used for selecting which sequences the annotation should be copied to. Click **Copy** to copy the annotation.

If you wish to copy all annotations on the sequence, click the **Copy All Annotations to other Sequences**.
Copied/transferred annotations will contain the same qualifier text as the original, i.e., the text is not updated. As an example, if the annotation contains 'translation' as qualifier text, this translation will be copied to the new sequence and will thus reflect the translation of the original sequence, and not the new sequence which may differ.

**Move sequences up and down** Sequences can be moved up and down in the alignment:

*drag the name of the sequence up or down*

When you move the mouse pointer over the label, the pointer will turn into a vertical arrow indicating that the sequence can be moved.

The sequences can also be sorted automatically to let you save time moving the sequences around. To sort the sequences alphabetically:

*Right-click the name of a sequence | Sort Sequences Alphabetically*

If you change the Sequence name (in the Sequence Layout view preferences), you will have to ask the program to sort the sequences again.

If you have one particular sequence that you would like to use as a reference sequence, it can be useful to move this to the top. This can be done manually, but it can also be done automatically:

*Right-click the name of a sequence | Move Sequence to Top*

The sequences can also be sorted by similarity, grouping similar sequences together:

*Right-click the name of a sequence | Sort Sequences by Similarity*

**Delete, rename and add sequences** Sequences can be removed from the alignment by right-clicking the label of a sequence:

*right-click label | Delete Sequence*

If you wish to delete several sequences, you can check all the sequences, right-click and choose Delete Marked Sequences. To show the checkboxes, you first have to click the Show Selection Boxes in the Side Panel.

A sequence can also be renamed:

*right-click label | Rename Sequence*

This will show a dialog, letting you rename the sequence. This will not affect the sequence that the alignment is based on.

Extra sequences can be added to the alignment by creating a new alignment where you select the current alignment and the extra sequences (see section 20.1).

The same procedure can be used for joining two alignments.

**20.3.1 Realignment**

Realigning a section of an alignment

If you have created an alignment, it is possible to realign a part of it, leaving the rest of the
alignment unchanged:

Select a part of the alignment to realign | Right-click the selection | Choose the option "Realign selection"

This will open a window allowing you to set the parameters for the realignment (see figure 20.10).

![Realignment window](image)

Figure 20.10: Realigning a section of an alignment.

Learn more about the options available to you in the sections 20.1.1 and 20.1.2.

It is possible for an alignment to become shorter or longer as a result of the realignment of a region. This is because gaps may have to be inserted in, or deleted from, the sequences not selected for realignment. This will only occur for entire columns of gaps in these sequences, ensuring that their relative alignment is unchanged.

Realigning a selection is a very powerful tool for editing alignments in several situations:

- **Removing changes.** If you change the alignment in a specific region manually but decide to undo all the edits you just made, you can easily select the region that was edited and realign it.

- **Adjusting the number of gaps.** If you have a region in an alignment which has too many gaps, you can select the region and realign it with a higher gap cost.

- **Combine with fixpoints.** When you have an alignment where two residues are not aligned although they should have been, you can set an alignment fixpoint on each of the two residues, select the region and realign it using the fixpoints. Now, the two residues are aligned with each other and everything in the selected region around them is adjusted to accommodate this change.

**Realigning a subset of aligned sequences**

To realign only a subset of the sequences of an alignment, you have to select the sequences you want to realign by click-and-drag on their entire length, and open the selection in a new view. This means that the sequences you want to select need to be situated on top of each other in a single stack.

A small stack is easily obtainable by dragging the sequences by their names to the top of the alignment. But when a large quantity of sequences needs to be moved to sit together, we recommend using the selection boxes that are available when checking the option "Show selection boxes" from the Alignment settings section in the right-hand side panel (figure 20.11).
Select all the sequences you want to realign independently of the rest of the alignment, and right-click on the name of one of the sequences to choose the option "Sort Sequences by Marked Status". This will bring all checkbox-selected items to the top of the alignment.

![Figure 20.11: Realigning a subset of the sequences that are part of an alignment. Note that we can see here the menu available when right clicking on the names of the sequences.](image1)

You can then easily click-and-drag your selection of sequences (this is made easier if you select the "No wrap" setting in the right-hand side panel). By right-clicking on the selected sequences (not on their names, but on the sequences themselves as seen in figure 20.12), you can choose the option "Open selection in a new view", with the ability to run any relevant tool on that sub-alignment.

![Figure 20.12: Open the selected sequences in a new window to realign them.](image2)

### 20.4 Join alignments

CLC Genomics Workbench can join several alignments into one. This feature can for example be used to construct "supergenes" for phylogenetic inference by joining alignments of several disjoint genes into one spliced alignment. Note, that when alignments are joined, all their annotations are carried over to the new spliced alignment.

Alignments can be joined by:

**Toolbox** | **Classical Sequence Analysis** | **Alignments and Trees** | **Join Alignments**

This opens the dialog shown in figure 20.13.
CHAPTER 20. SEQUENCE ALIGNMENT

If you have selected some alignments before choosing the Toolbox action, they are now listed in the Selected Elements window of the dialog. Use the arrows to add or remove alignments from the selected elements. In this example seven alignments are selected. Each alignment represents one gene that has been sequenced from five different bacterial isolates from the genus Nisseria. Clicking Next opens the dialog shown in figure 20.14.

To adjust the order of concatenation, click the name of one of the alignments, and move it up or down using the arrow buttons.

The result is seen in the lower part of figure 20.15.

**How alignments are joined** Alignments are joined by considering the sequence names in the individual alignments. If two sequences from different alignments have identical names, they are considered to have the same origin and are thus joined. Consider the joining of the alignments shown in figure 20.15 "Alignment of isolates_abcZ", "Alignment of isolates_aroE", "Alignment of isolates_adk" etc. If a sequence with the same name is found in the different alignments (in this case the name of the isolates: Isolate 1, Isolate 2, Isolate 3, Isolate 4, and Isolate 5), a joined alignment will exist for each sequence name. In the joined alignment the selected alignments will be fused with each other in the order they were selected (in this case the seven different genes from the five bacterial isolates). Note that annotations have been added to each individual sequence before aligning the isolates for one gene at the time in order to make it clear which sequences were fused to each other.

**20.5 Pairwise comparison**

For a given set of aligned sequences it is possible to make a pairwise comparison in which each pair of sequences are compared to each other. This provides an overview of the diversity among
Figure 20.15: The upper part of the figure shows two of the seven alignments for the genes "abcZ" and "aroE" respectively. Each alignment consists of sequences from one gene from five different isolates. The lower part of the figure shows the result of "Join Alignments". Seven genes have been joined to an artificial gene fusion, which can be useful for construction of phylogenetic trees in cases where only fractions of a genome is available. Joining of the alignments results in one row for each isolate consisting of seven fused genes. Each fused gene sequence corresponds to the number of uniquely named sequences in the joined alignments.

In CLC Genomics Workbench this is done by creating a comparison table:

**Toolbox | Classical Sequence Analysis ( ) | Alignments and Trees ( ) | Create Pairwise Comparison ( )**

This opens the dialog displayed in figure 20.16:

![Creating a pairwise comparison table](image)

Figure 20.16: Creating a pairwise comparison table.

Select at least two alignments alignment to compare. A pairwise comparison can also be performed for a selected part of an alignment:

**right-click on an alignment selection | Pairwise Comparison ( )**

There are five kinds of comparison that can be made between the sequences in the alignment, as shown in figure 20.17:

- **Gaps** Calculates the number of alignment positions where one sequence has a gap and the
CHAPTER 20. SEQUENCE ALIGNMENT

Figure 20.17: Adjusting parameters for pairwise comparison.

other does not.

- **Identities** Calculates the number of identical alignment positions to overlapping alignment positions between the two sequences. An overlapping alignment position is a position where at least one residue is present, rather than only gaps.

- **Differences** Calculates the number of alignment positions where one sequence is different from the other. This includes gap differences as in the Gaps comparison.

- **Distance** Calculates the Jukes-Cantor distance between the two sequences. This number is given as the Jukes-Cantor correction of the proportion between identical and overlapping alignment positions between the two sequences.

- **Percent identity** Calculates the percentage of identical residues in alignment positions to overlapping alignment positions between the two sequences.

20.5.1 The pairwise comparison table

The table shows the results of selected comparisons (see an example in figure 20.18). Since comparisons are often symmetric, the table can show the results of two comparisons at the same time, one in the upper-right and one in the lower-left triangle.

Figure 20.18: A pairwise comparison table.

Note that you can change the minimum and maximum values of the gradient coloring by sliding the corresponding cursor along the gradient in the right side panel of the comparison table. The
values that appear when you slide the cursor reflect the percentage of the range of values in
the table, and not absolute values.

The following settings are present in the side panel:

- **Contents**
  - **Upper comparison** Selects the comparison to show in the upper triangle of the table.
  - **Upper comparison gradient** Selects the color gradient to use for the upper triangle.
  - **Lower comparison** Selects the comparison to show in the lower triangle. Choose the
    same comparison as in the upper triangle to show all the results of an asymmetric
    comparison.
  - **Lower comparison gradient** Selects the color gradient to use for the lower triangle.
  - **Diagonal from upper** Use this setting to show the diagonal results from the upper
    comparison.
  - **Diagonal from lower** Use this setting to show the diagonal results from the lower
    comparison.
  - **No Diagonal**. Leaves the diagonal table entries blank.

- **Layout**
  - **Lock headers** Locks the sequence labels and table headers when scrolling the table.
  - **Sequence label** Changes the sequence labels.

- **Text format**
  - **Text size** Changes the size of the table and the text within it.
  - **Font** Changes the font in the table.
  - **Bold** Toggles the use of boldface in the table.

### 20.5.2 Bioinformatics explained: Multiple alignments

Multiple alignments are at the core of bioinformatical analysis. Often the first step in a chain of
bioinformatical analyses is to construct a multiple alignment of a number of homologs DNA or
protein sequences. However, despite their frequent use, the development of multiple alignment
algorithms remains one of the algorithmically most challenging areas in bioinformatical research.

Constructing a multiple alignment corresponds to developing a hypothesis of how a number of
sequences have evolved through the processes of character substitution, insertion and
deletion. The input to multiple alignment algorithms is a number of homologous sequences,
i.e., sequences that share a common ancestor and most often also share molecular function. The generated alignment is a table (see figure 20.19) where each row corresponds to an input
sequence and each column corresponds to a position in the alignment. An individual column in
this table represents residues that have all diverged from a common ancestral residue. Gaps in
the table (commonly represented by a ‘-’) represent positions where residues have been inserted
or deleted and thus do not have ancestral counterparts in all sequences.

**Use of multiple alignments**

Once a multiple alignment is constructed it can form the basis for a number of analyses:
• The phylogenetic relationship of the sequences can be investigated by tree-building methods based on the alignment.

• Annotation of functional domains, which may only be known for a subset of the sequences, can be transferred to aligned positions in other un-annotated sequences.

• Conserved regions in the alignment can be found which are prime candidates for holding functionally important sites.

• Comparative bioinformatical analysis can be performed to identify functionally important regions.

Figure 20.19: The tabular format of a multiple alignment of 24 Hemoglobin protein sequences. Sequence names appear at the beginning of each row and the residue position is indicated by the numbers at the top of the alignment columns. The level of sequence conservation is shown on a color scale with blue residues being the least conserved and red residues being the most conserved.

Constructing multiple alignments

Whereas the optimal solution to the pairwise alignment problem can be found in reasonable time, the problem of constructing a multiple alignment is much harder.

The first major challenge in the multiple alignment procedure is how to rank different alignments, i.e., which scoring function to use. Since the sequences have a shared history they are correlated through their phylogeny and the scoring function should ideally take this into account. Doing so is, however, not straightforward as it increases the number of model parameters considerably. It is therefore commonplace to either ignore this complication and assume sequences to be unrelated, or to use heuristic corrections for shared ancestry.

The second challenge is to find the optimal alignment given a scoring function. For pairs of sequences this can be done by dynamic programming algorithms, but for more than three sequences this approach demands too much computer time and memory to be feasible.

A commonly used approach is therefore to do progressive alignment [Feng and Doolittle, 1987] where multiple alignments are built through the successive construction of pairwise alignments. These algorithms provide a good compromise between time spent and the quality of the resulting alignment.

The method has the inherent drawback that once two sequences are aligned, there is no way of changing their relative alignment based on the information that additional sequences may
contribute later in the process. It is therefore important to make the best possible alignments early in the procedure, to avoid accumulating errors. To accomplish this, a tree of the sequences is usually constructed to guide the progressive alignment algorithm. And to overcome the problem of a time consuming tree construction step, we are using word matching, a method that group sequences in a very efficient way, saving much time, without reducing the resulting alignment accuracy significantly.

Our algorithm (developed by QIAGEN Aarhus) has two speed settings: "standard" and "fast". The **standard method** makes a fairly standard progressive alignment using the fast method of generating a guide tree. When aligning two alignments to each other, two matching columns are scored as the average of all the pairwise scores of the residues in the columns. The gap cost is affine, allowing a different cost for the first gapped position and for the consecutive gaps. This ensures that gaps are not spread out too much.

The **fast method** of alignment uses the same overall method, except that it uses fixpoints in the alignment algorithm based on short subsequences that are identical in the sequences that are being aligned. This allows similar sequences to be aligned much more efficiently, without reducing accuracy very much.

Phylogenetics describes the taxonomic classification of organisms based on their evolutionary history i.e. their phylogeny. Phylogenetics is therefore an integral part of the science of systematics that aims to establish the phylogeny of organisms based on their characteristics. Furthermore, phylogenetics is central to evolutionary biology as a whole as it is the condensation of the overall paradigm of how life arose and developed on earth. The focus of this module is the reconstruction and visualization of phylogenetic trees. Phylogenetic trees illustrate the inferred evolutionary history of a set of organisms, and makes it possible to e.g. identify groups of closely related organisms and observe clustering of organisms with common traits. See 21.4.1 for a more detailed introduction to phylogenetic trees.
CHAPTER 21. PHYLOGENETIC TREES

The viewer for visualizing and working with phylogenetic trees allows the user to create high-quality, publication-ready figures of phylogenetic trees. Large trees can be explored in two alternative tree layouts; circular and radial. The viewer supports importing, editing and visualization of metadata associated with nodes in phylogenetic trees.

Below is an overview of the main features of the phylogenetic tree editor. Further details can be found in the subsequent sections.

**Main features of the phylogenetic tree editor:**

- Circular and radial layouts.
- Import of metadata in Excel and CSV format.
- Tabular view of metadata with support for editing.
- Options for collapsing nodes based on bootstrap values.
- Re-ordering of tree nodes.
- Legends describing metadata.
- Visualization of metadata though e.g. node color, node shape, branch color, etc.
- Minimap navigation.
- Coloring and labeling of subtrees.
- Curved edges.
- Editable node sizes and line width.
- Intelligent visualization of overlapping labels and nodes.

For a given set of aligned sequences (see section 20.1) it is possible to infer their evolutionary relationships. In *CLC Genomics Workbench* this may be done either by using a distance based method or by using maximum likelihood (ML) estimation, which is a statistical approach (see Bioinformatics explained in section 21.4.1). Both approaches generate a phylogenetic tree.

Three tools are available for generating phylogenetic trees:

- **K-mer Based Tree Construction** is a distance-based method that can create trees based on multiple single sequences. K-mers are used to compute distance matrices for distance-based phylogenetic reconstruction tools such as neighbor joining and UPGMA (see section 21.4.1). This method is less precise than the Create Tree tool but it can cope with a very large number of long sequences as it does not require a multiple alignment. The k-mer based tree construction tool is especially useful for whole genome phylogenetic reconstruction where the genomes are closely related, i.e. they differ mainly by SNPs and contain no or few structural variations.

- **Maximum Likelihood Phylogeny** is the most advanced and time consuming method of the three mentioned. The maximum likelihood tree estimation is performed under the assumption of one of five substitution models: the Jukes-Cantor, the Kimura 80, the HKY and the GTR (also known as the REV model) models (see section 21.4 for further information...
about the models). Prior to using the Maximum Likelihood Phylogeny tool for creating a phylogenetic tree it is recommended to run the Model Testing tool (see section 21.3) in order to identify the best suitable models for creating a tree.

- **Create Tree** is a tool that uses distance estimates computed from multiple alignments to create trees. The user can select whether to use Jukes-Cantor distance correction or Kimura distance correction (Kimura 80 for nucleotides/Kimura protein for proteins) in combination with either the neighbor joining or UPGMA method (see section 21.4.1).

## 21.1 K-mer Based Tree Construction

The K-mer Based Tree Construction tool uses single sequences or sequence lists as input and is the simplest way of creating a distance-based phylogenetic tree. To run the K-mer Based Tree Construction tool:

**Toolbox | Classical Sequence Analysis | Alignments and Trees | K-mer Based Tree Construction**

Select sequences or a sequence list (figure 21.1):

![Figure 21.1: Select sequences needed for creating a tree with K-mer based tree construction.](image)

Next, select the construction method, specify the k-mer length and select a distance measure for tree construction (figure 21.2):

- **Tree construction**
  - **Tree construction method** The user is asked to specify which distance-based method to use for tree construction. There are two options (see section 21.4.1):
    - The **UPGMA** method. Assumes constant rate of evolution.
    - The **Neighbor Joining** method. Well suited for trees with varying rates of evolution.

- **K-mer settings**
CHAPTER 21. PHYLOGENETIC TREES

21.2 Create tree

The Create tree tool can be used to generate a distance-based phylogenetic tree with multiple alignments as input:

Toolbox | Classical Sequence Analysis ( ) | Alignments and Trees ( ) | Create Tree ( )

This will open the dialog displayed in figure 21.3:

![Create Tree Dialog]

If an alignment was selected before choosing the Toolbox action, this alignment is now listed in the Selected Elements window of the dialog. Use the arrows to add or remove elements from the Navigation Area. Click Next to adjust parameters.

Figure 21.4 shows the parameters that can be set for this distance-based tree creation:

- Tree construction (see section 21.4.1)
  - Tree construction method
    * The UPGMA method. Assumes constant rate of evolution.
The Neighbor Joining method. Well suited for trees with varying rates of evolution.

- Nucleotide distance measure
  - Jukes-Cantor. Assumes equal base frequencies and equal substitution rates.
  - Kimura 80. Assumes equal base frequencies but distinguishes between transitions and transversions.

- Protein distance measure
  - Jukes-Cantor. Assumes equal amino acid frequency and equal substitution rates.
  - Kimura protein. Assumes equal amino acid frequency and equal substitution rates. Includes a small correction term in the distance formula that is intended to give better distance estimates than Jukes-Cantor.

- Bootstrapping.
  - Perform bootstrap analysis. To evaluate the reliability of the inferred trees, CLC Genomics Workbench allows the option of doing a bootstrap analysis (see section 21.4.1). A bootstrap value will be attached to each node, and this value is a measure of the confidence in the subtree rooted at the node. The number of replicates used in the bootstrap analysis can be adjusted in the wizard. The default value is 100 replicates which is usually enough to distinguish between reliable and unreliable nodes in the tree. The bootstrap value assigned to each inner node in the output tree is the percentage (0-100) of replicates which contained the same subtree as the one rooted at the inner node.

For a more detailed explanation, see Bioinformatics explained in section 21.4.1.

21.3 Model Testing

As the Model Testing tool can help identify the best substitution model (21.4.1) to be used for Maximum Likelihood Phylogeny tree construction, it is recommended to run Model Testing before running the Maximum Likelihood Phylogeny tool.

The Model Testing tool uses four different statistical analyses:

- Hierarchical likelihood ratio test (hLRT)
- Bayesian information criterion (BIC)
CHAPTER 21. PHYLOGENETIC TREES

- Minimum theoretical information criterion (AIC)
- Minimum corrected theoretical information criterion (AICc)

To test the substitution models:

- Jukes-Cantor [Jukes and Cantor, 1969]
- Felsenstein 81 [Felsenstein, 1981]
- Kimura 80 [Kimura, 1980]
- HKY [Hasegawa et al., 1985]
- GTR (also known as the REV model) [Yang, 1994a]

To do model testing:

Toolbox | Classical Sequence Analysis | Alignments and Trees | Model Testing

Select the alignment that you wish to use for the tree construction (figure 21.5):

![Figure 21.5: Select alignment for model testing.]

Specify the parameters to be used for model testing (figure 21.6):

![Figure 21.6: Specify parameters for model testing.]

- Select base tree construction method
A base tree (a guiding tree) is required in order to be able to determine which model(s) would be the most appropriate to use to make the best possible phylogenetic tree from a specific alignment. The topology of the base tree is used in the hierarchical likelihood ratio test (hLRT), and the base tree is used as starting point for topology exploration in Bayesian information criterion (BIC), Akaike information criterion (or minimum theoretical information criterion) (AIC), and AICc (AIC with a correction for the sample size) ranking.

- **Construction method** A base tree is created automatically using one of two methods from the Create Tree tool:
  - The **UPGMA** method. Assumes constant rate of evolution.
  - The **Neighbor Joining** method. Well suited for trees with varying rates of evolution.

- **Hierarchical likelihood ratio test (hLRT) parameters** A statistical test of the goodness-of-fit between two models that compares a relatively more complex model to a simpler model to see if it fits a particular dataset significantly better.

  - **Perform hierarchical likelihood ratio test (hLRT)**
  - **Confidence level for LRT** The confidence level used in the likelihood ratio tests.

- **Bayesian information criterion (BIC) parameters**

  - **Compute Bayesian information criterion (BIC)** Rank substitution models based on Bayesian information criterion (BIC). Formula used is $\text{BIC} = -2\ln(L) + K \ln(n)$, where $\ln(L)$ is the log-likelihood of the best tree, $K$ is the number of parameters in the model, and $\ln(n)$ is the logarithm of the length of the alignment.

- **Minimum theoretical information criterion (AIC) parameters**

  - **Compute minimum theoretical information criterion (AIC)** Rank substitution models based on minimum theoretical information criterion (AIC). Formula used is $\text{AIC} = -2\ln(L) + 2K$, where $\ln(L)$ is the log-likelihood of the best tree, $K$ is the number of parameters in the model.

  - **Compute corrected minimum theoretical information criterion (AICc)** Rank substitution models based on minimum corrected theoretical information criterion (AICc). Formula used is $\text{AICc} = -2\ln(L) + 2K + 2K(K+1)/(n-K-1)$, where $\ln(L)$ is the log-likelihood of the best tree, $K$ is the number of parameters in the model, $n$ is the length of the alignment. AICc is recommended over AIC roughly when $n/K$ is less than 40.

The output from model testing is a report that lists all test results in table format. For each tested model the report indicate whether it is recommended to use rate variation or not. Topology variation is recommended in all cases.

From the listed test results, it is up to the user to select the most appropriate model. The different statistical tests will usually agree on which models to recommend although variations may occur. Hence, in order to select the best possible model, it is recommended to select the model that has proven to be the best by most tests.

### 21.4 Maximum Likelihood Phylogeny

To generate a maximum likelihood based phylogenetic tree:
Toolbox | Classical Sequence Analysis | Alignments and Trees | Maximum Likelihood Phylogeny

Figure 21.7: Select the alignment for tree construction.

Figure 21.8: Adjusting parameters for maximum likelihood phylogeny

The following parameters can be set for the maximum likelihood based phylogenetic tree (see figure 21.8):

- **Starting tree**
  - **Construction method** Specify the tree construction method which should be used to create the initial tree. There are two possibilities:
    - Neighbor Joining
    - UPGMA
  - **Exiting start tree** Alternatively, an existing tree can be used as starting tree for the tree reconstruction. Click on the folder icon to the right of the text field to use the browser function to identify the desired starting tree.

- **Select substitution model**
Nucleotide substitution model CLC Genomics Workbench allows maximum likelihood tree estimation to be performed under the assumption of one of five nucleotide substitution models:

- Jukes-Cantor [Jukes and Cantor, 1969]
- Felsenstein 81 [Felsenstein, 1981]
- Kimura 80 [Kimura, 1980]
- HKY [Hasegawa et al., 1985]
- General Time Reversible (GTR) (also known as the REV model) [Yang, 1994a]

All models are time-reversible. In the Kimura 80 and HKY models, the user may set a transition/transversion ratio value, which will be used as starting value for optimization or as a fixed value, depending on the level of estimation chosen by the user. For further details, see 21.4.1.

Protein substitution model CLC Genomics Workbench allows maximum likelihood tree estimation to be performed under the assumption of one of four protein substitution models:

- Bishop-Friday [Bishop and Friday, 1985]
- Dayhoff (PAM) [Dayhoff et al., 1978]
- JTT [Jones et al., 1992]
- WAG [Whelan and Goldman, 2001]

The Bishop-Friday substitution model is similar to the Jukes-Cantor model for nucleotide sequences, i.e. it assumes equal amino acid frequencies and substitution rates. This is an unrealistic assumption and we therefore recommend using one of the remaining three models. The Dayhoff, JTT and WAG substitution models are all based on large scale experiments where amino acid frequencies and substitution rates have been estimated by aligning thousands of protein sequences. For these models, the maximum likelihood tool does not estimate parameters, but simply uses those determined from these experiments.

Rate variation

To enable variable substitution rates among individual nucleotide sites in the alignment, select the include rate variation box. When selected, the discrete gamma model of Yang [Yang, 1994b] is used to model rate variation among sites. The number of categories used in the discretization of the gamma distribution as well as the gamma distribution parameter may be adjusted by the user (as the gamma distribution is restricted to have mean 1, there is only one parameter in the distribution).

Estimation

Estimation is done according to the maximum likelihood principle, that is, a search is performed for the values of the free parameters in the model assumed that results in the highest likelihood of the observed alignment [Felsenstein, 1981]. By ticking the estimate substitution rate parameters box, maximum likelihood values of the free parameters in the rate matrix describing the assumed substitution model are found. If the Estimate topology box is selected, a search in the space of tree topologies for that which best explains the alignment is performed. If left un-ticked, the starting topology is kept fixed at that of the starting tree.

The Estimate Gamma distribution parameter is active if rate variation has been included in the model and in this case allows estimation of the Gamma distribution
parameter to be switched on or off. If the box is left un-ticked, the value is fixed at that given in the Rate variation part. In the absence of rate variation estimation of substitution parameters and branch lengths are carried out according to the expectation maximization algorithm [Dempster et al., 1977]. With rate variation the maximization algorithm is performed. The topology space is searched according to the PHYML method [Guindon and Gascuel, 2003], allowing efficient search and estimation of large phylogenies. Branch lengths are given in terms of expected numbers of substitutions per nucleotide site.

In the next step of the wizard it is possible to perform bootstrapping (figure 21.9).

![Figure 21.9: Adjusting parameters for ML phylogeny](image)

- **Bootstrapping**
  - **Perform bootstrap analysis.** To evaluate the reliability of the inferred trees, CLC Genomics Workbench allows the option of doing a bootstrap analysis (see section 21.4.1). A bootstrap value will be attached to each node, and this value is a measure of the confidence in the subtree rooted at the node. The number of replicates in the bootstrap analysis can be adjusted in the wizard by specifying the number of times to resample the data. The default value is 100 resamples. The bootstrap value assigned to a node in the output tree is the percentage (0-100) of the bootstrap resamples which resulted in a tree containing the same subtree as that rooted at the node.

### 21.4.1 Bioinformatics explained

#### The phylogenetic tree

The evolutionary hypothesis of a phylogeny can be graphically represented by a phylogenetic tree. Figure 21.10 shows a proposed phylogeny for the great apes, Hominidae, taken in part from Purvis [Purvis, 1995]. The tree consists of a number of nodes (also termed vertices) and branches (also termed edges). These nodes can represent either an individual, a species, or a higher grouping and are thus broadly termed taxonomic units. In this case, the terminal nodes (also called leaves or tips of the tree) represent extant species of Hominidae and are the operational taxonomic units (OTUs). The internal nodes, which here represent extinct common ancestors of the great apes, are termed hypothetical taxonomic units since they are not directly observable.

The ordering of the nodes determine the tree topology and describes how lineages have diverged over the course of evolution. The branches of the tree represent the amount of evolutionary divergence between two nodes in the tree and can be based on different measurements. A tree is completely specified by its topology and the set of all edge lengths.
The phylogenetic tree in figure 21.10 is rooted at the most recent common ancestor of all Hominidae species, and therefore represents a hypothesis of the direction of evolution e.g. that the common ancestor of gorilla, chimpanzee and man existed before the common ancestor of chimpanzee and man. In contrast, an unrooted tree would represent relationships without assumptions about ancestry.

**Modern usage of phylogenies**

Besides evolutionary biology and systematics the inference of phylogenies is central to other areas of research.

As more and more genetic diversity is being revealed through the completion of multiple genomes, an active area of research within bioinformatics is the development of comparative machine learning algorithms that can simultaneously process data from multiple species [Siepel and Haussler, 2004]. Through the comparative approach, valuable evolutionary information can be obtained about which amino acid substitutions are functionally tolerant to the organism and which are not. This information can be used to identify substitutions that affect protein function and stability, and is of major importance to the study of proteins [Knudsen and Miyamoto, 2001]. Knowledge of the underlying phylogeny is, however, paramount to comparative methods of inference as the phylogeny describes the underlying correlation from shared history that exists between data from different species.

In molecular epidemiology of infectious diseases, phylogenetic inference is also an important tool. The very fast substitution rate of microorganisms, especially the RNA viruses, means that these show substantial genetic divergence over the time-scale of months and years. Therefore, the phylogenetic relationship between the pathogens from individuals in an epidemic can be resolved and contribute valuable epidemiological information about transmission chains and epidemiologically significant events [Leitner and Albert, 1999], [Forsberg et al., 2001].

**Substitution models and distance estimation**

When estimating the evolutionary distance between organisms, one needs a model of how frequently different mutations occur in the DNA. Such models are known as substitution models. Our Model Testing and Maximum Likelihood Phylogeny tools currently support the five nucleotide substitution models listed here:

- Jukes-Cantor [Jukes and Cantor, 1969]
Common to all these models is that they assume mutations at different sites in the genome occur independently and that the mutations at each site follow the same common probability distribution. Thus all five models provide relative frequencies for each of the 16 possible DNA substitutions (e.g. $C \rightarrow A$, $C \rightarrow C$, $C \rightarrow G$, ...).

The Jukes-Cantor and Kimura 80 models assume equal base frequencies and the HKY and GTR models allow the frequencies of the four bases to differ (they will be estimated by the observed frequencies of the bases in the alignment). In the Jukes-Cantor model all substitutions are assumed to occur at equal rates, in the Kimura 80 and HKY models transition and transversion rates are allowed to differ (substitution between two purines ($A \leftrightarrow G$) or two pyrimidines ($C \leftrightarrow T$) are transitions and purine - pyrimidine substitutions are transversions). The GTR model is the general time reversible model that allows all substitutions to occur at different rates. For the substitution rate matrices describing the substitution models we use the parametrization of Yang [Yang, 1994a].

For protein sequences, our Maximum Likelihood Phylogeny tool supports four substitution models:

- Bishop-Friday [Bishop and Friday, 1985]
- Dayhoff (PAM) [Dayhoff et al., 1978]
- JTT [Jones et al., 1992]
- WAG [Whelan and Goldman, 2001]

As with nucleotide substitution models, it is assumed that mutations at different sites in the genome occur independently and according to the same probability distribution.

The Bishop-Friday model assumes all amino acids occur with same frequency and that all substitutions are equally likely. This is the simplest model, but also the most unrealistic. The remaining three models use amino acid frequencies and substitution rates which have been determined from large scale experiments where huge sets of protein sequences have been aligned and rates have been estimated. These three models reflect the outcome of three different experiments. We recommend using WAG as these rates where estimated from the largest experiment.

**K-mer based distance estimation**

K-mer based distance estimation is an alternative to estimating evolutionary distance based on multiple alignments. At a high level, the distance between two sequences is defined by first collecting the set of k-mers (subsequences of length k) occurring in the two sequences. From these two sets, the evolutionary distance between the two organisms is now defined by measuring how different the two sets are. The more the two sets look alike, the smaller is the evolutionary distance. The main motivation for estimating evolutionary distance based on k-mers,
is that it is computationally much faster than first constructing a multiple alignment. Experiments show that phylogenetic tree reconstruction using k-mer based distances can produce results comparable to the slower multiple alignment based methods [Blaisdell, 1989].

All of the k-mer based distance measures completely ignores the ordering of the k-mers inside the input sequences. Hence, if the selected k value (the length of the sequences) is too small, very distantly related organisms may be assigned a small evolutionary distance (in the extreme case where k is 1, two organisms will be treated as being identical if the frequency of each nucleotide/amino-acid is the same in the two corresponding sequences). In the other extreme, the k-mers should have a length (k) that is somewhat below the average distance between mismatches if the input sequences were aligned (in the extreme case of k=the length of the sequences, two organisms have a maximum distance if they are not identical). Thus the selected k value should not be too large and not too small. A general rule of thumb is to only use k-mer based distance estimation for organisms that are not too distantly related.

**Formal definition of distance.** In the following, we give a more formal definition of the three supported distance measures: Euclidian-squared, Mahalanobis and Fractional common k-mer count. For all three, we first associate a point \( p(s) \) to every input sequence \( s \). Each point \( p(s) \) has one coordinate for every possible length k sequence (e.g. if \( s \) represent nucleotide sequences, then \( p(s) \) has \( 4^k \) coordinates). The coordinate corresponding to a length k sequence \( x \) has the value: "number of times \( x \) occurs as a subsequence in \( s \)". Now for two sequences \( s_1 \) and \( s_2 \), their evolutionary distance is defined as follows:

- **Euclidian squared**: For this measure, the distance is simply defined as the (squared Euclidian) distance between the two points \( p(s_1) \) and \( p(s_2) \), i.e.

  \[
  \text{dist}(s_1, s_2) = \sum_i (p(s_1)_i - p(s_2)_i)^2.
  \]

- **Mahalanobis**: This measure is essentially a fine-tuned version of the Euclidian squared distance measure. Here all the counts \( p(s_j)_i \), are "normalized" by dividing with the standard deviation \( \sigma_j \) of the count for the k-mer. The revised formula thus becomes:

  \[
  \text{dist}(s_1, s_2) = \sum_i (p(s_1)_i/\sigma_i - p(s_2)_i/\sigma_i)^2.
  \]

  Here the standard deviations can be computed directly from a set of equilibrium frequencies for the different bases, see [Gentleman and Mullin, 1989].

- **Fractional common k-mer count**: For the last measure, the distance is computed based on the minimum count of every k-mer in the two sequences, thus if two sequences are very different, the minimums will all be small. The formula is as follows:

  \[
  \text{dist}(s_1, s_2) = \log(0.1 + \sum_i (\min(p(s_1)_i, p(s_2)_i)/(\min(n, m) - k + 1))).
  \]

  Here \( n \) is the length of \( s_1 \) and \( m \) is the length of \( s_2 \). This method has been described in [Edgar, 2004].

In experiments performed in [Höhl et al., 2007], the Mahalanobis distance measure seemed to be the best performing of the three supported measures.
Distance based reconstruction methods

Distance based phylogenetic reconstruction methods use a pairwise distance estimate between the input organisms to reconstruct trees. The distances are an estimate of the evolutionary distance between each pair of organisms which are usually computed from DNA or amino acid sequences. Given two homologous sequences a distance estimate can be computed by aligning the sequences and then counting the number of positions where the sequences differ. The number of differences is called the observed number of substitutions and is usually an underestimate of the real distance as multiple mutations could have occurred at any position. To correct for these hidden substitutions a substitution model, such as Jukes-Cantor or Kimura 80, can be used to get a more precise distance estimate (see section 21.4.1).

To correct for these hidden substitutions a substitution model, such as Jukes-Cantor or Kimura 80, can be used to get a more precise distance estimate.

Alternatively, k-mer based methods or SNP based methods can be used to get a distance estimate without the use of substitution models.

After distance estimates have been computed, a phylogenetic tree can be reconstructed using a distance based reconstruction method. Most distance based methods perform a bottom up reconstruction using a greedy clustering algorithm. Initially, each input organism is put in its own cluster which corresponds to a leaf node in the resulting tree. Next, pairs of clusters are iteratively joined into higher level clusters, which correspond to connecting two nodes in the tree with a new parent node. When a single node remains, the tree is reconstructed.

The CLC Genomics Workbench provides two of the most widely used distance based reconstruction methods:

- The UP**GMA** method [Michener and Sokal, 1957] which assumes a constant rate of evolution (molecular clock hypothesis) in the different lineages. This method reconstructs trees by iteratively joining the two nearest clusters until there is only one cluster left. The result of the UPGMA method is a rooted bifurcating tree annotated with branch lengths.

- The Neighbor Joining method [Saitou and Nei, 1987] attempts to reconstruct a minimum evolution tree (a tree where the sum of all branch lengths is minimized). Opposite to the UPGMA method, the neighbor joining method is well suited for trees with varying rates of evolution in different lineages. A tree is reconstructed by iteratively joining clusters which are close to each other but at the same time far from all other clusters. The resulting tree is a bifurcating tree with branch lengths. Since no particular biological hypothesis is made about the placement of the root in this method, the resulting tree is unrooted.

Maximum likelihood reconstruction methods

Maximum likelihood (ML) based reconstruction methods [Felsenstein, 1981] seek to identify the most probable tree given the data available, i.e. maximize $P(\text{tree}|\text{data})$ where the $\text{tree}$ refers to a tree topology with branch lengths while $\text{data}$ is usually a set of sequences. However, it is not possible to compute $P(\text{tree}|\text{data})$ so instead ML based methods have to compute the probability of the data given a tree, i.e. $P(\text{data}|\text{tree})$. The ML tree is then the tree which makes the data most probable. In other words, ML methods search for the tree that gives the highest probability of producing the observed sequences. This is done by searching through the space of all possible trees while computing an ML estimate for each tree. Computing an ML estimate for
a tree is time consuming and since the number of tree topologies grows exponentially with the number of leaves in a tree, it is infeasible to explore all possible topologies. Consequently, ML methods must employ search heuristics that quickly converges towards a tree with a likelihood close to the real ML tree.

The likelihood of trees are computed using an explicit model of evolution such as the Jukes-Cantor or Kimura 80 models. Choosing the right model is often important to get a good result. To help users choose the correct model for a data set, the Model Testing tool (see section 21.3) can be used to test a range of different models for input nucleotide sequences.

Choosing the right model is often important to get a good result and to help users choose the correct model for a data set, the Model Testing tool (see section 21.3) can be used to test a range of different models for nucleotide input sequences.

The search heuristics which are commonly used in ML methods requires an initial phylogenetic tree as a starting point for the search. An initial tree which is close to the optimal solution, can reduce the running time of ML methods and improve the chance of finding a tree with a large likelihood. A common way of reconstructing a good initial tree is to use a distance based method such as UPGMA or neighbor-joining to produce a tree based on a multiple alignment.

**Bootstrap tests**

Bootstrap tests [Felsenstein, 1985] is one of the most common ways to evaluate the reliability of the topology of a phylogenetic tree. In a bootstrap test, trees are evaluated using Efron’s re-sampling technique [Efron, 1982], which samples nucleotides from the original set of sequences as follows:

Given an alignment of $n$ sequences (rows) of length $l$ (columns), we randomly choose $l$ columns in the alignment with replacement and use them to create a new alignment. The new alignment has $n$ rows and $l$ columns just like the original alignment but it may contain duplicate columns and some columns in the original alignment may not be included in the new alignment. From this new alignment we reconstruct the corresponding tree and compare it to the original tree. For each subtree in the original tree we search for the same subtree in the new tree and add a score of one to the node at the root of the subtree if the subtree is present in the new tree. This procedure is repeated a number of times (usually around 100 times). The result is a counter for each interior node of the original tree, which indicate how likely it is to observe the exact same subtree when the input sequences are sampled. A bootstrap value is then computed for each interior node as the percentage of resampled trees that contained the same subtree as that rooted at the node.

Bootstrap values can be seen as a measure of how reliably we can reconstruct a tree, given the sequence data available. If all trees reconstructed from resampled sequence data have very different topologies, then most bootstrap values will be low, which is a strong indication that the topology of the original tree cannot be trusted.

**Scale bar**

The scale bar unit depends on the distance measure used and the tree construction algorithm used. The trees produced using the Maximum Likelihood Phylogeny tool has a very specific interpretation: A distance of $x$ means that the expected number of substitutions/changes per nucleotide (amino acid for protein sequences) is $x$. i.e. if the distance between two taxa is 0.01,
you expected a change in each nucleotide independently with probability 1%. For the remaining algorithms, there is not as nice an interpretation. The distance depends on the weight given to different mutations as specified by the distance measure.

21.5 Tree Settings

The Tree Settings Side Panel found in the left side of the view area can be used to adjust the tree layout and to visualize metadata that is associated with the tree nodes. The following section describes the visualization options available from the Tree Settings side panel. Note however that editing legend boxes related to metadata can be done directly from editing the metadata table (see section 21.6).

The preferred tree layout settings (user defined tree settings) can be saved and applied via the top right Save Tree Settings (figure 21.11). Settings can either be saved For This Tree Only or for all saved phylogenetic trees (For Tree View in General). The first option will save the layout of the tree for that tree only and it ensures that the layout is preserved even if it is exported and opened by a different user. The second option stores the layout globally in the Workbench and makes it available to other trees through the Apply Saved Settings option.

![Figure 21.11: Save, remove or apply preferred layout settings.](image)

21.5.1 Minimap

The Minimap is a navigation tool that shows a small version of the tree. A grey square indicates the specific part of the tree that is visible in the View Area (figure 21.12). To navigate the tree using the Minimap, click on the Minimap with the mouse and move the grey square around within the Minimap.

21.5.2 Tree layout

The Tree Layout can be adjusted in the Side Panel (figure 21.13).

- **Layout** Selects one of the five layout types: Phylogram, Cladogram, Circular Phylogram, Circular Cladogram or Radial. Note that only the Cladogram layouts are available if all branches in the tree have zero length.
  - **Phylogram** is a rooted tree where the edges have "lengths", usually proportional to the inferred amount of evolutionary change to have occurred along each branch.
  - **Cladogram** is a rooted tree without branch lengths which is useful for visualizing the topology of trees.
Figure 21.12: Visualization of a phylogenetic tree. The grey square in the Minimap shows the part of the tree that is shown in the View Area.

- **Circular Phylogram** is also a phylogram but with the leaves in a circular layout.
- **Circular Cladogram** is also a cladogram but with the leaves in a circular layout.
- **Radial** is an unrooted tree that has the same topology and branch lengths as the rooted styles, but lacks any indication of evolutionary direction.

- **Ordering** The nodes can be ordered after the branch length; either **Increasing** (shown in figure 21.13) or **Decreasing**.
- **Reset Tree Topology** Resets to the default tree topology and node order (see figure 21.13).
- **Fixed width on zoom** Locks the horizontal size of the tree to the size of the main window. Zoom is therefore only performed on the vertical axis when this option is enabled.
- **Show as unrooted tree** The tree can be shown with or without a root.

### 21.5.3 Node settings

The nodes can be manipulated in several ways.

- **Leaf node symbol** Leaf nodes can be shown as a range of different symbols (Dot, Box, Circle, etc.).
- **Internal node symbols** The internal nodes can also be shown with a range of different symbols (Dot, Box, Circle, etc.).
- **Max. symbol size** The size of leaf- and internal node symbols can be adjusted.
- **Avoid overlapping symbols** The symbol size will be automatically limited to avoid overlaps between symbols in the current view.
- **Node color** Specify a fixed color for all nodes in the tree.

The node layout settings in the Side Panel are shown in figure 21.14.
Figure 21.13: The tree layout can be adjusted in the Side Panel. The top part of the figure shows a tree with increasing node order. In the bottom part of the figure the tree has been reverted to the original tree topology.

21.5.4 Label settings

- **Label font settings** Can be used to specify/adjust font type, size and typography (Bold, Italic or normal).

- **Hide overlapping labels** Disable automatic hiding of overlapping labels and display all labels even if they overlap.

- **Show internal node labels** Labels for internal nodes of the tree (if any) can be displayed. Please note that subtrees and nodes can be labeled with a custom text. This is done by right clicking the node and selecting **Edit Label** (see figure 21.15).

- **Show leaf node labels** Leaf node labels can be shown or hidden.

- **Rotate Subtree labels** Subtree labels can be shown horizontally or vertically. Labels are shown vertically when "Rotate subtree labels" has been selected. Subtree labels can be added with the right click option "Set Subtree Label" that is enabled from "Decorate subtree" (see section 21.5.9).

- **Align labels** Align labels to the node furthest from the center of the tree so that all labels are positioned next to each other. The exact behavior depends on the selected tree layout.
Figure 21.14: The Node Layout settings. Node color is specified by metadata and is therefore inactive in this example.

- Connect labels to nodes Adds a thin line from the leaf node to the aligned label. Only possible when Align labels option is selected.

Figure 21.15: "Edit label" in the right click menu can be used to customize the label text. The way node labels are displayed can be controlled through the labels settings in the right side panel.

When working with big trees there is typically not enough space to show all labels. As illustrated in figure 21.15, only some of the labels are shown. The hidden labels are illustrated with thin horizontal lines (figure 21.16).
There are different ways of showing more labels. One way is to reduce the font size of the labels, which can be done under **Label font settings** in the Side Panel. Another option is to zoom in on specific areas of the tree (figure 21.16 and figure 21.17). The last option is to disable **Hide overlapping labels** under "Label settings" in the right side panel. When this option is unchecked all labels are shown even if the text overlaps. When allowing overlapping labels it is usually a good idea to disable **Show label background** under "Background settings" (see section 21.5.5).

**Note!** When working with a tree with hidden labels, it is possible to make the hidden label text appear by moving the mouse over the node with the hidden label.

**Note!** The text within labels can be edited by editing the metadata table values directly.

---

**Figure 21.16:** The zoom function in the upper right corner of CLC Genomics Workbench can be used to zoom in on a particular region of the tree. When the zoom function has been activated, use the mouse to drag a rectangle over the area that you wish to zoom in at.

**Figure 21.17:** After zooming in on a region of interest more labels become visible. In this example all labels are now visible.
21.5.5 Background settings

- **Show label background** Show a background color for each label. Once ticked, it is possible to specify whether to use a fixed color or to use the color that is associated with the selected metadata category.

21.5.6 Branch layout

- **Branch length font settings** Specify/adjust font type, size and typography (Bold, Italic or normal).
- **Line color** Select the default line color.
- **Line width** Select the width of branches (1.0-3.0 pixels).
- **Curvature** Adjust the degree of branch curvature to get branches with round corners.
- **Min. length** Select a minimum branch length. This option can be used to prevent nodes connected with a short branch to cluster at the parent node.
- **Show branch lengths** Show or hide the branch lengths.

The branch layout settings in the Side Panel are shown in figure 21.18.

![Figure 21.18: Branch Layout settings.](image)

21.5.7 Bootstrap settings

Bootstrap values can be shown on the internal nodes. The bootstrap values are shown in percent and can be interpreted as confidence levels where a bootstrap value close to 100 indicate a clade, which is strongly supported by the data from which the tree was reconstructed. Bootstrap values are useful for identifying clades in the tree where the topology (and branch lengths) should not be trusted.

Some branches in rooted trees may not have bootstrap values. Trees constructed with neighbour joining are unrooted and to correctly visualize them, the "Radial" view is required. In all other tree views we need a root to visualize the tree. An "artificial node" and therefore an extra branch are created for such visualization to achieve this, which makes it look like a bootstrap value is missing.
- **Bootstrap value font settings** Specify/adjust font type, size and typography (Bold, Italic or normal).

- **Show bootstrap values (%)** Show or hide bootstrap values. When selected, the bootstrap values (in percent) will be displayed on internal nodes if these have been computed during the reconstruction of the tree.

- **Bootstrap threshold (%)** When specifying a bootstrap threshold, the branch lengths can be controlled manually by collapsing internal nodes with bootstrap values under a certain threshold.

- **Highlight bootstrap ≥ (%)** Highlights branches where the bootstrap value is above the user defined threshold.

### 21.5.8 Visualizing metadata

Metadata associated with a phylogenetic tree (described in detail in section 21.6) can be visualized in a number of different ways:

- **Node shape** Different node shapes are available to visualize metadata.
- **Node symbol size** Change the node symbol size to visualize metadata.
- **Node color** Change the node color to visualize metadata.
- **Label text** The metadata can be shown directly as text labels as shown in figure 21.19.
- **Label text color** The label text can be colored and used to visualize metadata (see figure 21.19).
- **Label background color** The background color of node text labels can be used to visualize metadata.
- **Branch color** Branch colors can be changed according to metadata.
- **Metadata layers** Color coded layers shown next to leaf nodes.

Please note that when visualizing metadata through a tree property that can be adjusted in the right side panel (such as node color or node size), an exclamation mark will appear next to the control for that property to indicate that the setting is inactive because it is defined by metadata (see figure 21.14).

### 21.5.9 Node right click menu

Additional options for layout and extraction of subtree data are available when right clicking the nodes (figure 21.15):

- **Set Root At This Node** Re-root the tree using the selected node as root. Please note that re-rooting will change the tree topology.
- **Set Root Above Node** Re-root the tree by inserting a node between the selected node and its parent. Useful for rooting trees using an outgroup.
Figure 21.19: Different types of metadata can be visualized by adjusting node size, shape, and color. Two color-code metadata layers (Year and Host) are shown in the right side of the tree.

- **Collapse** Branches associated with a selected node can be collapsed with or without the associated labels. Collapsed branches can be uncollapsed using the *Uncollapse* option in the same menu.

- **Hide** Can be used to hide a node or a subtree. Hidden nodes or subtrees can be shown again using the *Show Hidden Subtree* function on a node which is root in a subtree containing hidden nodes (see figure 21.20). When hiding nodes, a new button appears labeled "Show X hidden nodes" in the Side Panel under "Tree Layout" (figure 21.21). When pressing this button, all hidden nodes are shown again.

- **Decorate Subtree** A subtree can be labeled with a customized name, and the subtree lines and/or background can be colored. To save the decoration, see figure 21.11 and use option: **Save/Restore Settings | Save Tree View Settings On This Tree View only**.

- **Order Subtree** Rearrange leaves and branches in a subtree by Increasing/Decreasing depth, respectively. Alternatively, change the order of a node’s children by left clicking and dragging one of the node’s children.

- **Extract Sequence List** Sequences associated with selected leaf nodes are extracted to a new sequence list.

- **Align Sequences** Sequences associated with selected leaf nodes are extracted and used as input to the *Create Alignment* tool.

- **Assign Metadata** Metadata can be added, deleted or modified. To add new metadata categories a new "Name" must be assigned. (This will be the column header in the metadata table). To add a new metadata category, enter a value in the "Value" field. To delete values, highlight the relevant nodes and right click on the selected nodes. In the dialog that appears, use the drop-down list to select the name of the desired metadata.
Figure 21.20: A subtree can be hidden by selecting "Hide Subtree" and is shown again when selecting "Show Hidden Subtree" on a parent node.

Figure 21.21: When hiding nodes, a new button labeled "Show X hidden nodes" appears in the Side Panel under "Tree Layout". When pressing this button, all hidden nodes are brought back.

category and leave the value field empty. When pressing "Add" the values for the selected metadata category will be deleted from the selected nodes. Metadata can be modified in the same way, but instead of leaving the value field empty, the new value should be entered.

- **Edit label** Edit the text in the selected node label. Labels can be shown or hidden by using the Side Panel:  
  
  **Label settings | Show internal node labels**
21.6 Metadata and phylogenetic trees

When a tree is reconstructed, some mandatory metadata will be added to nodes in the tree. These metadata are special in the sense that the tree viewer has specialized features for visualizing the data and some of them cannot be edited. The mandatory metadata include:

- **Node name** The node name.
- **Branch length** The length of the branch, which connects a node to the parent node.
- **Bootstrap value** The bootstrap value for internal nodes.
- **Size** The length of the sequence which corresponds to each leaf node. This only applies to leaf nodes.
- **Start of sequence** The first 50bp of the sequence corresponding to each leaf node.

To view metadata associated with a phylogenetic tree, click on the table icon at the bottom of the tree. If you hold down the Ctrl key (or ⌘ on Mac) while clicking on the table icon, you will be able to see both the tree and the table in a split view (figure 21.22).

![Figure 21.22: Tabular metadata that is associated with an existing tree shown in a split view. Note that Unknown written in italics (black branches) refer to missing metadata, while Unknown in regular font refers to metadata labeled as “Unknown”.](image)

Additional metadata can be associated with a tree by clicking the Import Metadata button. This will open up the dialog shown in figure 21.23.

To associate metadata with an existing tree a common denominator is required. This is achieved by mapping the node names in the "Name" column of the metadata table to the names that
have been used in the metadata table to be imported. In this example the "Strain" column holds the names of the nodes and this column must be assigned "Name" to allow the importer to associate metadata with nodes in the tree.

It is possible to import a subset of the columns in a set of metadata. An example is given in figure 21.23. The column "H" is not relevant to import and can be excluded simply by leaving the text field at the top row of the column empty.

Figure 21.23: Import of metadata for a tree. The second column named "Strain" is choosen as the common denominator by entering "Name" in the text field of the column. The column labeled "H" is ignored by not assigning a column heading to this column.

### 21.6.1 Table Settings and Filtering

How to use the metadata table (see figure 21.24):

- **Column width** The column width can be adjusted in two ways; *Manually* or *Automatically*.
- **Show column** Selects which metadata categories that are shown in the table layout.
- **Filtering Metadata information** Metadata information in a table can be filtered by a simple- or advanced mode (this is described in the CLC Genomics Workbench manual, Appendix D, Filtering tables).

### 21.6.2 Add or modify metadata on a tree

It is possible to add and modify metadata from both the tree view and the table view.

Metadata can be added and edited in the metadata table by using the following right click options (see figure 21.25):
• **Assign Metadata** The right click option "Assign Metadata" can be used for four purposes.

  - To add new metadata categories (columns). In this case, a new "Name" must be assigned, which will be the column header. To add a new column requires that a value is entered in the "Value" field. This can be done by right clicking anywhere in the table.
  
  - To add values to one or more rows in an existing column. In this case, highlight the relevant rows and right click on the selected rows. In the dialog that appears, use the drop-down list to select the name of the desired column and enter a value.

  - To delete values from an existing column. This is done in the same way as when adding a new value, with the only exception that the value field should be left empty.

  - To delete metadata columns. This is done by selecting all rows in the table followed by a right click anywhere in the table. Select the name of the column to delete from the drop down menu and leave the value field blank. When pressing "Add", the selected column will disappear.

• **Delete Metadata "column header"** This is the most simple way of deleting a metadata column. Click on one of the rows in the column to delete and select "Delete column header".

• **Edit "column header"** To modify existing metadata point, right click on a cell in the table and select the "Edit column header". To edit multiple entries at once, select multiple rows in the table, right click a selected cell in the column you want to edit and choose "Edit column header" (see an example in figure 21.26). This will change values in all selected rows in the column that was clicked.
Figure 21.26: To modify existing metadata, click on the specific field, select "Edit <column header>" and provide a new value.

21.6.3 Undefined metadata values on a tree

When visualizing a metadata category where one or more nodes in the tree have undefined values (empty fields in the table), these nodes will be visualized using a default value in italics in the top of the legend (see the entry "Unknown" in figure 21.27). To remove this entry in the legend, all nodes must have a value assigned in the corresponding metadata category.

Figure 21.27: A legend for a metadata category where one or more values are undefined. Fill your metadata table with a value of your choice to edit the mention of "Unknown" in the legend. Note that the "Unknown" that is not in italics is used for data that had a value written as "Unknown" in the metadata table.

21.6.4 Selection of specific nodes

Selection of nodes in a tree is automatically synchronized to the metadata table and the other way around. Nodes in a tree can be selected in three ways:

- **Selection of a single node** Click once on a single node. Additional nodes can be added by holding down Ctrl (or ⌘ for Mac) and clicking on them (see figure 21.28).
- **Selecting all nodes in a subtree** Double clicking on a inner node results in the selection of all nodes in the subtree rooted at the node.
- **Selection via the Metadata table** Select one or more entries in the table. The corresponding nodes will now be selected in the tree.
It is possible to extract a subset of the underlying sequence data directly through either the tree viewer or the metadata table as follows. Select one or more nodes in the tree where at least one node has a sequence attached. Right click one of the selected nodes and choose **Extract Sequence List**. This will generate a new sequence list containing all sequences attached to the selected nodes. The same functionality is available in the metadata table where sequences can be extracted from selected rows using the right click menu. Please note that all extracted sequences are copies and any changes to these sequences will not be reflected in the tree.

When analyzing a phylogenetic tree it is often convenient to have a multiple alignment of sequences from e.g. a specific clade in the tree. A quick way to generate such an alignment is to first select one or more nodes in the tree (or the corresponding entries in the metadata table) and then select **Align Sequences** in the right click menu. This will extract the sequences corresponding to the selected elements and use a copy of them as input to the multiple alignment tool (see section 20.5.2). Next, change relevant option in the multiple alignment wizard that pops up and click **Finish**. The multiple alignment will now be generated.

Figure 21.28: *Cherry picking nodes in a tree. The selected leaf sequences can be extracted by right clicking on one of the selected nodes and selecting "Extract Sequence List". It is also possible to Align Sequences directly by right clicking on the nodes or leaves.*

Ribonucleic acid (RNA) is a nucleic acid polymer that plays several important roles in the cell. As for proteins, the three dimensional shape of an RNA molecule is important for its molecular function. A number of tertiary RNA structures are known from crystallography but de novo prediction of tertiary structures is not possible with current methods. However, as for proteins RNA tertiary structures can be characterized by secondary structural elements which are hydrogen bonds within the molecule that form several recognizable "domains" of secondary structure like stems, hairpin loops, bulges and internal loops. A large part of the functional information is thus contained in the secondary structure of the RNA molecule, as shown by the high degree of base-pair conservation observed in the evolution of RNA molecules.
Computational prediction of RNA secondary structure is a well-defined problem and a large body of work has been done to refine prediction algorithms and to experimentally estimate the relevant biological parameters.

In CLC Genomics Workbench we offer the user a number of tools for analyzing and displaying RNA structures. These include:

- Secondary structure prediction using state-of-the-art algorithms and parameters
- Calculation of full partition function to assign probabilities to structural elements and hypotheses
- Scanning of large sequences to find local structure signal
- Inclusion of experimental constraints to the folding process
- Advanced viewing and editing of secondary structures and structure information

### 22.1 RNA secondary structure prediction

CLC Genomics Workbench uses a minimum free energy (MFE) approach to predict RNA secondary structure. Here, the stability of a given secondary structure is defined by the amount of free energy used (or released) by its formation. The more negative free energy a structure has, the more likely is its formation since more stored energy is released by the event.

Free energy contributions are considered additive, so the total free energy of a secondary structure can be calculated by adding the free energies of the individual structural elements. Hence, the task of the prediction algorithm is to find the secondary structure with the minimum free energy. As input to the algorithm empirical energy parameters are used. These parameters summarize the free energy contribution associated with a large number of structural elements. A detailed structure overview can be found in section 22.5.

In CLC Genomics Workbench, structures are predicted by a modified version of Professor Michael Zukers well-known algorithm [Zuker, 1989b] which is the algorithm behind a number of RNA-folding packages including MFOLD. Our algorithm is a dynamic programming algorithm for free energy minimization which includes free energy increments for coaxial stacking of stems when they are either adjacent or separated by a single mismatch. The thermodynamic energy parameters used are from Mfold version 3, see [http://mfold.rna.albany.edu/?q=mfold/mfold-references](http://mfold.rna.albany.edu/?q=mfold/mfold-references).

#### 22.1.1 Selecting sequences for prediction

Secondary structure prediction can be accessed in the Toolbox:

Toolbox | Classical Sequence Analysis | RNA Structure | Predict Secondary Structure

This opens the dialog shown in figure 22.1.

If you have selected sequences before choosing the Toolbox action, they are now listed in the Selected Elements window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements. You can use both DNA and RNA sequences - DNA will be folded as if it were RNA.
CHAPTER 22. RNA STRUCTURE

Figure 22.1: Selecting RNA or DNA sequences for structure prediction (DNA is folded as if it was RNA).

22.1.2 Secondary structure prediction parameters

Click Next to adjust secondary structure prediction parameters (figure 22.2).

Figure 22.2: Adjusting parameters for secondary structure prediction.

Structure output

The predict secondary structure algorithm always calculates the minimum free energy structure of the input sequence. In addition to this, it is also possible to compute a sample of suboptimal structures by ticking the checkbox Compute sample of suboptimal structures.

Subsequently, you can specify how many structures to include in the output. The algorithm then iterates over all permissible canonical base pairs and computes the minimum free energy and associated secondary structure constrained to contain a specified base pair. These structures are then sorted by their minimum free energy and the most optimal are reported given the specified number of structures. Note that two different sub-optimal structures can have the same minimum free energy. Further information about suboptimal folding can be found in [Zuker, 1989a].
Partition function

The predicted minimum free energy structure gives a point-estimate of the structural conformation of an RNA molecule. However, this procedure implicitly assumes that the secondary structure is at equilibrium, that there is only a single accessible structure conformation, and that the parameters and model of the energy calculation are free of errors.

Obvious deviations from these assumptions make it clear that the predicted MFE structure may deviate somewhat from the actual structure assumed by the molecule. This means that rather than looking at the MFE structure it may be informative to inspect statistical properties of the structural landscape to look for general structural properties which seem to be robust to minor variations in the total free energy of the structure (see [Mathews et al., 2004]).

To this end CLC Genomics Workbench allows the user to calculate the complete secondary structure partition function using the algorithm described in [Mathews et al., 2004] which is an extension of the seminal work by [McCaskill, 1990].

There are two options regarding the partition function calculation:

- **Calculate base pair probabilities.** This option invokes the partition function calculation and calculates the marginal probabilities of all possible base pairs and the marginal probability that any single base is unpaired.

- **Create plot of marginal base pairing probabilities.** This creates a plot of the marginal base pair probability of all possible base pairs as shown in figure 22.3.

![Figure 22.3: The marginal base pair probability of all possible base pairs.](image)

The marginal probabilities of base pairs and of bases being unpaired are distinguished by colors which can be displayed in the normal sequence view using the Side Panel - see section 22.2.3 and also in the secondary structure view. An example is shown in figure 22.4. Furthermore, the marginal probabilities are accessible from tooltips when hovering over the relevant parts of the structure.
Figure 22.4: Marginal probability of base pairs shown in linear view (top) and marginal probability of being unpaired shown in the secondary structure 2D view (bottom).

**Advanced options**

The free energy minimization algorithm includes a number of advanced options:

- **Avoid isolated base pairs.** The algorithm filters out isolated base pairs (i.e. stems of length 1).
- **Apply different energy rules for Grossly Asymmetric Interior Loops (GAIL).** Compute the minimum free energy applying different rules for Grossly Asymmetric Interior Loops (GAIL). A Grossly Asymmetry Interior Loop (GAIL) is an interior loop that is $1 \times n$ or $n \times 1$ where $n > 2$ (see [http://mfold.rna.albany.edu/doc/mfold-manual/node5.php](http://mfold.rna.albany.edu/doc/mfold-manual/node5.php)).
- **Include coaxial stacking energy rules.** Include free energy increments of coaxial stacking for adjacent helices [Mathews et al., 2004].
- **Apply base pairing constraints.** With base pairing constraints, you can easily add
experimental constraints to your folding algorithm. When you are computing suboptimal structures, it is not possible to apply base pair constraints. The possible base pairing constraints are:

- Force two equal length intervals to form a stem.
- Prohibit two equal length intervals to form a stem.
- Prohibit all nucleotides in a selected region to be a part of a base pair.

Base pairing constraints have to be added to the sequence before you can use this option - see below.

- **Maximum distance between paired bases.** Forces the algorithms to only consider RNA structures of a given upper length by setting a maximum distance between the base pair that opens a structure.

### Specifying structure constraints

Structure constraints can serve two purposes in CLC Genomics Workbench: they can act as experimental constraints imposed on the MFE structure prediction algorithm or they can form a structure hypothesis to be evaluated using the partition function (see section 22.1.2).

To force two regions to form a stem, open a normal sequence view and:

Select the two regions you want to force by pressing Ctrl while selecting - (use ⌘ on Mac) | right-click the selection | Add Structure Prediction Constraints | Force Stem Here

This will add an annotation labeled "Forced Stem" to the sequence (see figure 22.5).

![Figure 22.5: Force a stem of the selected bases.](image)

Using this procedure to add base pairing constraints will force the algorithm to compute minimum free energy and structure with a stem in the selected region. The two regions must be of equal length.

To prohibit two regions to form a stem, open the sequence and:

Select the two regions you want to prohibit by pressing Ctrl while selecting - (use ⌘ on Mac) | right-click the selection | Add Structure Prediction Constraints | Prohibit Stem Here

This will add an annotation labeled "Prohibited Stem" to the sequence (see figure 22.6).

Using this procedure to add base pairing constraints will force the algorithm to compute minimum free energy and structure without a stem in the selected region. Again, the two selected regions must be of equal length.

To prohibit a region to be part of any base pair, open the sequence and:
Select the bases you don’t want to base pair | right-click the selection | Add Structure Prediction Constraints | Prohibit From Forming Base Pairs

This will add an annotation labeled "No base pairs" to the sequence, see 22.7.

Using this procedure to add base pairing constraints will force the algorithm to compute minimum free energy and structure without a base pair containing any residues in the selected region.

When you click Predict secondary structure and click Next, check Apply base pairing constraints in order to force or prohibit stem regions or prohibit regions from forming base pairs.

You can add multiple base pairing constraints, e.g. simultaneously adding forced stem regions and prohibited stem regions and prohibit regions from forming base pairs.

### 22.1.3 Structure as annotation

You can choose to add the elements of the best structure as annotations (see figure 22.8).

This makes it possible to use the structure information in other analysis in the CLC Genomics Workbench. You can e.g. align different sequences and compare their structure predictions.

Note that possibly existing structure annotation will be removed when a new structure is calculated and added as annotations.

If you generate multiple structures, only the best structure will be added as annotations. If you wish to add one of the sub-optimal structures as annotations, this can be done from the Show Secondary Structure Table described in section 22.2.2.
22.2 View and edit secondary structures

When you predict RNA secondary structure (see section 22.1), the resulting predictions are attached to the sequence and can be shown as:

- Annotations in the ordinary sequence views (Linear sequence view, Annotation table etc. This is only possible if this has been chosen in the dialog in figure 22.2. See an example in figure 22.8.
- Symbolic representation below the sequence (see section 22.2.3).
- A graphical view of the secondary structure (see section 22.2.1).
- A tabular view of the energy contributions of the elements in the structure. If more than one structure have been predicted, the table is also used to switch between the structures shown in the graphical view. The table is described in section 22.2.2.

22.2.1 Graphical view and editing of secondary structure

To show the secondary view of an already open sequence, click the Show Secondary Structure 2D View button at the bottom of the sequence view.

If the sequence is not open, click Show and select Secondary Structure 2D View. This will open a view similar to the one shown in figure 22.9.

![Figure 22.9: The secondary structure view of an RNA sequence zoomed in.](image)

Like the normal sequence view, you can use Zoom in and Zoom out. Zooming in will reveal the residues of the structure as shown in figure 22.9. For large structures, zooming out will give you an overview of the whole structure.

Side Panel settings

The settings in the Side Panel are a subset of the settings in the normal sequence view described in section 11.1.1. However, there are two additional groups of settings unique to the secondary structure 2D view: Secondary structure.
• **Follow structure selection.** This setting pertains to the connection between the structures in the secondary structure table. If this option is checked, the structure displayed in the secondary structure 2D view will follow the structure selections made in this table. See section 22.2.2 for more information.

• **Layout strategy.** Specify the strategy used for the layout of the structure. In addition to these strategies, you can also modify the layout manually as explained in the next section.
  
  - **Auto.** The layout is adjusted to minimize overlapping structure elements [Han et al., 1999]. This is the default setting (see figure 22.10).
  
  - **Proportional.** Arc lengths are proportional to the number of residues (see figure 22.11). Nothing is done to prevent overlap.
  
  - **Even spread.** Stems are spread evenly around loops as shown in figure 22.12.

• **Reset layout.** If you have manually modified the layout of the structure, clicking this button will reset the structure to the way it was laid out when it was created.

![Figure 22.10: Auto layout. Overlaps are minimized.](image)

![Figure 22.11: Proportional layout. Length of the arc is proportional to the number of residues in the arc.](image)

![Figure 22.12: Even spread. Stems are spread evenly around loops.](image)

### Selecting and editing

When you are in **Selection mode**, you can select parts of the structure like in a normal sequence view:
Press down the mouse button where the selection should start | move the mouse cursor to where the selection should end | release the mouse button

One of the advantages of the secondary structure 2D view is that it is integrated with other views of the same sequence. This means that any selection made in this view will be reflected in other views (see figure 22.13).

![Image of secondary structure view and linear sequence view](image)

**Figure 22.13: A split view of the secondary structure view and a linear sequence view.**

If you make a selection in another sequence view, this will also be reflected in the secondary structure view.

The CLC Genomics Workbench seeks to produce a layout of the structure where none of the elements overlap. However, it may be desirable to manually edit the layout of a structure for ease of understanding or for the purpose of publication.

To edit a structure, first select the Pan (pan) mode in the Tool bar (right-click on the zoom icon below the View Area). Now place the mouse cursor on the opening of a stem, and a visual indication of the anchor point for turning the substructure will be shown (see figure 22.14).

![Image of anchor point for rotating substructure](image)

**Figure 22.14: The blue circle represents the anchor point for rotating the substructure.**

Click and drag to rotate the part of the structure represented by the line going from the anchor point. In order to keep the bases in a relatively sequential arrangement, there is a restriction...
on how much the substructure can be rotated. The highlighted part of the circle represents the angle where rotating is allowed.

In figure 22.15, the structure shown in figure 22.14 has been modified by dragging with the mouse.

![Figure 22.15: The structure has now been rotated.](image)

Press **Reset layout** in the **Side Panel** to reset the layout to the way it looked when the structure was predicted.

### 22.2.2 Tabular view of structures and energy contributions

There are three main reasons to use the **Secondary structure table**:

- If more than one structure is predicted (see section 22.1), the table provides an overview of all the structures which have been predicted.
- With multiple structures you can use the table to determine which structure should be displayed in the Secondary structure 2D view (see section 22.2.1).
- The table contains a hierarchical display of the elements in the structure with detailed information about each element’s energy contribution.

To show the secondary structure table of an already open sequence, click the **Show Secondary Structure Table** button at the bottom of the sequence view.

If the sequence is not open, click **Show** and select **Secondary Structure Table**.

This will open a view similar to the one shown in figure 22.16.

On the left side, all computed structures are listed with the information about structure name, when the structure was created, the free energy of the structure and the probability of the structure if the partition function was calculated. Selecting a row (equivalent: a structure) will display a tree of the contained substructures with their contributions to the total structure free energy. Each substructure contains a union of nested structure elements and other substructures (see a detailed description of the different structure elements in section 22.5.2). Each substructure
contributes a free energy given by the sum of its nested substructure energies and energies of its nested structure elements.

The substructure elements to the right are ordered after their occurrence in the sequence; they are described by a region (the sequence positions covered by this substructure) and an energy contribution. Three examples of mixed substructure elements are "Stem base pairs", "Stem with bifurcation" and "Stem with hairpin".

The "Stem base pairs"-substructure is simply a union of stacking elements. It is given by a joined set of base pair positions and an energy contribution displaying the sum of all stacking element-energies.

The "Stem with bifurcation"-substructure defines a substructure enclosed by a specified base pair with and with energy contribution $\Delta G$. The substructure contains a "Stem base pairs"-substructure and a nested bifurcated substructure (multi loop). Also bulge and interior loops can occur separating stem regions.

The "Stem with hairpin"-substructure defines a substructure starting at a specified base pair with an enclosed substructure-energy given by $\Delta G$. The substructure contains a "Stem base pairs"-substructure and a hairpin loop. Also bulge and interior loops can occur, separating stem regions.

In order to describe the tree ordering of different substructures, we use an example as a starting point (see figure 22.17).

The structure is a (disjoint) nested union of a "Stem with bifurcation"-substructure and a dangling nucleotide. The nested substructure energies add up to the total energy. The "Stem with bifurcation"-substructure is again a (disjoint) union of a "Stem base pairs"-substructure joining position 1-7 with 64-70 and a multi loop structure element opened at base pair$(7,64)$. To see these structure elements, simply expand the "Stem with bifurcation" node (see figure 22.18).

The multi loop structure element is a union of three "Stem with hairpin"-substructures and contributions to the multi loop opening considering multi loop base pairs and multi loop arcs.

Selecting an element in the table to the right will make a corresponding selection in the Show Secondary Structure 2D View ( ) if this is also open and if the "Follow structure selection" has been set in the editors side panel. In figure 22.18 the "Stem with bifurcation" is selected in the table, and this part of the structure is high-lighted in the Secondary Structure 2D view.
The correspondence between the table and the structure editor makes it easy to inspect the thermodynamic details of the structure while keeping a visual overview as shown in the above figures.

**Handling multiple structures**

The table to the left offers a number of tools for working with structures. Select a structure, right-click, and the following menu items will be available:

- **Open Secondary Structure in 2D View**. This will open the selected structure in the Secondary structure 2D view.

- **Annotate Sequence with Secondary Structure**. This will add the structure elements as annotations to the sequence. Note that existing structure annotations will be removed.

- **Rename Secondary Structure**. This will allow you to specify a name for the structure to be displayed in the table.

- **Delete Secondary Structure**. This will delete the selected structure.

- **Delete All Secondary Structures**. This will delete all the selected structures. Note that once you save and close the view, this operation is irreversible. As long as the view is open, you can **Undo** the operation.

22.2.3 Symbolic representation in sequence view

In the **Side Panel** of normal sequence views, you will find an extra group under **Nucleotide info** called **Secondary Structure**. This is used to display a symbolic representation of the
Figure 22.18: Now the "Stem with bifurcation" node has been selected in the table and a corresponding selection has been made in the view of the secondary structure to the left.

secondary structure along the sequence (see figure 22.19).

Figure 22.19: The secondary structure visualized below the sequence and with annotations shown above.

The following options can be set:

- **Show all structures.** If more than one structure is predicted, this option can be used if all the structures should be displayed.

- **Show first.** If not all structures are shown, this can be used to determine the number of structures to be shown.

- **Sort by.** When you select to display e.g. four out of eight structures, this option determines
which the “first four” should be.

- Sort by ∆G.
- Sort by name.
- Sort by time of creation.

If these three options do not provide enough control, you can rename the structures in a meaningful alphabetical way so that you can use the “name” to display the desired ones.

- **Base pair symbol.** How a base pair should be represented (see figure 22.19).
- **Unpaired symbol.** How bases which are not part of a base pair should be represented (see figure 22.19).
- **Height.** When you zoom out, this option determines the height of the symbols as shown in figure 22.20 (when zoomed in, there is no need for specifying the height).
- **Base pair probability.** See section 22.2.4 below).

When you zoom in and out, the appearance of the symbols change. In figure 22.19, the view is zoomed in. In figure 22.20 you see the same sequence zoomed out to fit the width of the sequence.

![Secondary structure visualization](image)

*Figure 22.20: The secondary structure visualized below the sequence and with annotations shown above. The view is zoomed out to fit the width of the sequence.*

### 22.2.4 Probability-based coloring

In the **Side Panel** of both linear and secondary structure 2D views, you can choose to color structure symbols and sequence residues according to the probability of base pairing / not base pairing, as shown in figure 22.4.

In the linear sequence view ( ), this is found in **Nucleotide info** under **Secondary structure**, and in the secondary structure 2D view ( ), it is found under **Residue coloring**.

For both paired and unpaired bases, you can set the foreground color and the background color to a gradient with the color at the left side indicating a probability of 0, and the color at the right side indicating a probability of 1.

Note that you have to **Zoom to 100%** ( ) in order to see the coloring.
22.3 Evaluate structure hypothesis

Hypotheses about an RNA structure can be tested using CLC Genomics Workbench. A structure hypothesis $H$ is formulated using the structural constraint annotations described in section 22.1.2. By adding several annotations complex structural hypotheses can be formulated (see 22.21).

Given the set $S$ of all possible structures, only a subset of these $S_H$ will comply with the formulated hypotheses. We can now find the probability of $H$ as:

$$P(H) = \frac{\sum_{s_H \in S_H} P(s_H)}{\sum_{s \in S} P(s)} = \frac{P_{H}}{P_{\text{full}}},$$

where $P_{H}$ is the partition function calculated for all structures permissible by $H$ ($S_H$) and $P_{\text{full}}$ is the full partition function. Calculating the probability can thus be done with two passes of the partition function calculation, one with structural constraints, and one without. 22.21.

![Figure 22.21: Two constraints defining a structural hypothesis.](image)

22.3.1 Selecting sequences for evaluation

The evaluation is started from the Toolbox:

Toolbox | Classical Sequence Analysis (🌊) | RNA Structure (확) | Evaluate Structure Hypothesis (확)

This opens the dialog shown in figure 22.22.

![Figure 22.22: Selecting RNA or DNA sequences for evaluating structure hypothesis.](image)

If you have selected sequences before choosing the Toolbox action, they are now listed in the Selected Elements window of the dialog. Use the arrows to add or remove sequences or
sequence lists from the selected elements. Note, that the selected sequences must contain a structure hypothesis in the form of manually added constraint annotations.

Click **Next** to adjust evaluation parameters (see figure 22.23).

![Figure 22.23: Adjusting parameters for hypothesis evaluation.](image)

The partition function algorithm includes a number of advanced options:

- **Avoid isolated base pairs.** The algorithm filters out isolated base pairs (i.e. stems of length 1).

- **Apply different energy rules for Grossly Asymmetric Interior Loops (GAIL).** Compute the minimum free energy applying different rules for Grossly Asymmetry Interior Loops (GAIL). A Grossly Asymmetry Interior Loop (GAIL) is an interior loop that is $1 \times n$ or $n \times 1$ where $n > 2$ (see [http://mfold.rna.albany.edu/doc/mfold-manual/node5.php](http://mfold.rna.albany.edu/doc/mfold-manual/node5.php)).

- **Include coaxial stacking energy rules.** Include free energy increments of coaxial stacking for adjacent helices [Mathews et al., 2004].

### 22.3.2 Probabilities

After evaluation of the structure hypothesis an annotation is added to the input sequence. This annotation covers the same region as the annotations that constituted the hypothesis and contains information about the probability of the evaluated hypothesis (see figure 22.24).

![Figure 22.24: This hypothesis has a probability of 0.338 as shown in the annotation.](image)

### 22.4 Structure scanning plot

In **CLC Genomics Workbench** it is possible to scan larger sequences for the existence of local conserved RNA structures. The structure scanning approach is similar in spirit to the works
of [Workman and Krogh, 1999] and [Clote et al., 2005]. The idea is that if natural selection is operating to maintain a stable local structure in a given region, then the minimum free energy of the region will be markedly lower than the minimum free energy found when the nucleotides of the subsequence are distributed in random order.

The algorithm works by sliding a window along the sequence. Within the window, the minimum free energy of the subsequence is calculated. To evaluate the significance of the local structure signal its minimum free energy is compared to a background distribution of minimum free energies obtained from shuffled sequences, using Z-scores [Rivas and Eddy, 2000]. The Z-score statistics corresponds to the number of standard deviations by which the minimum free energy of the original sequence deviates from the average energy of the shuffled sequences. For a given Z-score, the statistical significance is evaluated as the probability of observing a more extreme Z-score under the assumption that Z-scores are normally distributed [Rivas and Eddy, 2000].

### 22.4.1 Selecting sequences for scanning

The scanning is started from the Toolbox:

Toolbox | Classical Sequence Analysis | RNA Structure | Evaluate Structure

This opens the dialog shown in figure 22.25.

![Figure 22.25: Selecting RNA or DNA sequences for structure scanning.](image)

If you have selected sequences before choosing the Toolbox action, they are now listed in the **Selected Elements** window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements.

Click **Next** to adjust scanning parameters (see figure 22.26).

The first group of parameters pertain to the methods of sequence resampling. There are four ways of resampling, all described in detail in [Clote et al., 2005]:

- **Mononucleotide shuffling.** Shuffle method generating a sequence of the exact same mononucleotide frequency
- **Dinucleotide shuffling.** Shuffle method generating a sequence of the exact same dinucleotide frequency
- **Mononucleotide sampling from zero order Markov chain.** Resampling method generating a sequence of the same expected mononucleotide frequency.
- **Dinucleotide sampling from first order Markov chain.** Resampling method generating a sequence of the same expected dinucleotide frequency.
CHAPTER 22. RNA STRUCTURE

Figure 22.26: Adjusting parameters for structure scanning.

The second group of parameters pertain to the scanning settings and include:

- **Window size.** The width of the sliding window.
- **Number of samples.** The number of times the sequence is resampled to produce the background distribution.
- **Step increment.** Step increment when plotting sequence positions against scoring values.

The third parameter group contains the output options:

- **Z-scores.** Create a plot of Z-scores as a function of sequence position.
- **P-values.** Create a plot of the statistical significance of the structure signal as a function of sequence position.

22.4.2 The structure scanning result

The output of the analysis are plots of Z-scores and probabilities as a function of sequence position. A strong propensity for local structure can be seen as spikes in the graphs (see figure 22.27).

22.5 Bioinformatics explained: RNA structure prediction by minimum free energy minimization

RNA molecules are hugely important in the biology of the cell. Besides their rather simple role as an intermediate messenger between DNA and protein, RNA molecules can have a plethora of biologic functions. Well known examples of this are the infrastructural RNAs such as tRNAs, rRNAs and snRNAs, but the existence and functionality of several other groups of non-coding RNAs are currently being discovered. These include micro- (miRNA), small interfering- (siRNA), Piwi interacting- (piRNA) and small modulatory RNAs (smRNA) [Costa, 2007].
A common feature of many of these non-coding RNAs is that the molecular structure is important for the biological function of the molecule.

Ideally, biological function is best interpreted against a 3D structure of an RNA molecule. However, 3D structure determination of RNA molecules is time-consuming, expensive, and difficult [Shapiro et al., 2007] and there is therefore a great disparity between the number of known RNA sequences and the number of known RNA 3D structures.

However, as it is the case for proteins, RNA tertiary structures can be characterized by secondary structural elements. These are defined by hydrogen bonds within the molecule that form several recognizable "domains" of secondary structure like stems, hairpin loops, bulges and internal loops (see below). Furthermore, the high degree of base-pair conservation observed in the evolution of RNA molecules shows that a large part of the functional information is actually contained in the secondary structure of the RNA molecule.

Fortunately, RNA secondary structure can be computationally predicted from sequence data allowing researchers to map sequence information to functional information. The subject of this paper is to describe a very popular way of doing this, namely free energy minimization. For an in-depth review of algorithmic details, we refer the reader to [Mathews and Turner, 2006].

### 22.5.1 The algorithm

Consider an RNA molecule and one of its possible structures $S_1$. In a stable solution there will be an equilibrium between unstructured RNA strands and RNA strands folded into $S_1$. The propensity of a strand to leave a structure such as $S_1$ (the stability of $S_1$), is determined by the free energy change involved in its formation. The structure with the lowest free energy ($S_{\text{min}}$) is
the most stable and will also be the most represented structure at equilibrium. The objective of minimum free energy (MFE) folding is therefore to identify \( S_{\text{min}} \) amongst all possible structures.

In the following, we only consider structures without pseudoknots, i.e. structures that do not contain any non-nested base pairs.

Under this assumption, a sequence can be folded into a single coherent structure or several sequential structures that are joined by unstructured regions. Each of these structures is a union of well described structure elements (see below for a description of these). The free energy for a given structure is calculated by an additive nearest neighbor model. Additive, means that the total free energy of a secondary structure is the sum of the free energies of its individual structural elements. Nearest neighbor, means that the free energy of each structure element depends only on the residues it contains and on the most adjacent Watson-Crick base pairs.

The simplest method to identify \( S_{\text{min}} \) would be to explicitly generate all possible structures, but it can be shown that the number of possible structures for a sequence grows exponentially with the sequence length [Zuker and Sankoff, 1984] leaving this approach unfeasible. Fortunately, a two step algorithm can be constructed which implicitly surveys all possible structures without explicitly generating the structures [Zuker and Stiegler, 1981]: The first step determines the free energy for each possible sequence fragment starting with the shortest fragments. Here, the lowest free energy for longer fragments can be expediently calculated from the free energies of the smaller sub-sequences they contain. When this process reaches the longest fragment, i.e., the complete sequence, the MFE of the entire molecule is known. The second step is called traceback, and uses all the free energies computed in the first step to determine \( S_{\text{min}} \) - the exact structure associated with the MFE. Acceptable calculation speed is achieved by using dynamic programming where sub-sequence results are saved to avoid recalculation. However, this comes at the price of a higher requirement for computer memory.

The structure element energies that are used in the recursions of these two steps, are derived from empirical calorimetric experiments performed on small molecules see e.g. [Mathews et al., 1999].

**Suboptimal structures determination**

A number of known factors violate the assumptions that are implicit in MFE structure prediction. [Schroeder et al., 1999] and [Chen et al., 2004] have shown experimental indications that the thermodynamic parameters are sequence dependent. Moreover, [Longfellow et al., 1990] and [Kierzek et al., 1999], have demonstrated that some structural elements show non-nearest neighbor effects. Finally, single stranded nucleotides in multi loops are known to influence stability [Mathews and Turner, 2002].

These phenomena can be expected to limit the accuracy of RNA secondary structure prediction by free energy minimization and it should be clear that the predicted MFE structure may deviate somewhat from the actual preferred structure of the molecule. This means that it may be informative to inspect the landscape of suboptimal structures which surround the MFE structure to look for general structural properties which seem to be robust to minor variations in the total free energy of the structure.

An effective procedure for generating a sample of suboptimal structures is given in [Zuker, 1989a]. This algorithm works by going through all possible Watson-Crick base pair in the molecule. For each of these base pairs, the algorithm computes the most optimal structure
among all the structures that contain this pair, see figure 22.28.

Figure 22.28: A number of suboptimal structures have been predicted using CLC Genomics Workbench and are listed at the top left. At the right hand side, the structural components of the selected structure are listed in a hierarchical structure and on the left hand side the structure is displayed.
22.5.2 Structure elements and their energy contribution

In this section, we classify the structure elements defining a secondary structure and describe their energy contribution.

![Diagrams of RNA secondary structures]

Figure 22.29: The different structure elements of RNA secondary structures predicted with the free energy minimization algorithm in CLC Genomics Workbench. See text for a detailed description.

**Nested structure elements**

The structure elements involving nested base pairs can be classified by a given base pair and the other base pairs that are nested and accessible from this pair. For a more elaborate description we refer the reader to [Sankoff et al., 1983] and [Zuker and Sankoff, 1984].

If the nucleotides with position number \((i, j)\) form a base pair and \(i < k, l < j\), then we say that the base pair \((k, l)\) is accessible from \((i, j)\) if there is no intermediate base pair \((i', j')\) such that \(i < i' < k, l < j' < j\). This means that \((k, l)\) is nested within the pair \(i, j\) and there is no other base pair in between.
Using the number of accessible base pairs, we can define the following distinct structure elements:

1. **Hairpin loop** (\(\text{hairpin}\)). A base pair with 0 other accessible base pairs forms a **hairpin loop**. The energy contribution of a hairpin is determined by the length of the unpaired (loop) region and the two bases adjacent to the closing base pair which is termed a terminal mismatch (see figure 22.29A).

2. A base pair with 1 accessible base pair can give rise to three distinct structure elements:
   - **Stacking of base pairs** (\(\text{stacking}\)). A stacking of two consecutive pairs occur if \(i' - i = 1 = j - j'\). Only canonical base pairs (\(A - U\) or \(G - C\) or \(G - U\)) are allowed (see figure 22.29B). The energy contribution is determined by the type and order of the two base pairs.
   - **Bulge** (\(\text{bulge}\)). A bulge loop occurs if \(i' - i > 1\) or \(j - j' > 1\), but not both. This means that the two base pairs enclose an unpaired region of length 0 on one side and an unpaired region of length \(\geq 1\) on the other side (see figure 22.29C). The energy contribution of a bulge is determined by the length of the unpaired (loop) region and the two closing base pairs.
   - **Interior loop** (\(\text{interior}\)). An interior loop occurs if both \(i' - i > 1\) and \(i - j' > 1\). This means that the two base pairs enclose an unpaired region of length \(\geq 1\) on both sides (see figure 22.29D). The energy contribution of an interior loop is determined by the length of the unpaired (loop) region and the four unpaired bases adjacent to the opening- and the closing base pair.

3. **Multi loop opened** (\(\text{multi loop}\)). A base pair with more than two accessible base pairs gives rise to a **multi loop**, a loop from which three or more stems are opened (see figure 22.29E). The energy contribution of a multi loop depends on the number of **Stems opened in multi-loop** (\(\text{Stems opened in multi-loop}\)) that protrude from the loop.

**Other structure elements**

- A collection of single stranded bases not accessible from any base pair is called an **exterior (or external) loop** (see figure 22.29F). These regions do not contribute to the total free energy.
- **Dangling nucleotide** (\(\text{dangling}\)). A **dangling nucleotide** is a single stranded nucleotide that forms a stacking interaction with an adjacent base pair. A dangling nucleotide can be a \(3'\) or \(5'\)-dangling nucleotide depending on the orientation (see figure 22.29G). The energy contribution is determined by the single stranded nucleotide, its orientation and on the adjacent base pair.
- **Non-GC terminating stem** (\(\text{Non-GC}\)). If a base pair other than a G-C pair is found at the end of a stem, an energy penalty is assigned (see figure 22.29H).
- **Coaxial interaction** (\(\text{coaxial}\)). Coaxial stacking is a favorable interaction of two stems where the base pairs at the ends can form a stacking interaction. This can occur between stems in a multi loop and between the stems of two different sequential structures. Coaxial stacking can occur between stems with no intervening nucleotides (adjacent stems) and between stems with one intervening nucleotide from each strand (see figure 22.29I). The energy contribution is determined by the adjacent base pairs and the intervening nucleotides.
Experimental constraints

A number of techniques are available for probing RNA structures. These techniques can determine individual components of an existing structure such as the existence of a given base pair. It is possible to add such experimental constraints to the secondary structure prediction based on free energy minimization (see figure 22.30) and it has been shown that this can dramatically increase the fidelity of the secondary structure prediction [Mathews and Turner, 2006].

![Figure 22.30: Known structural features can be added as constraints to the secondary structure prediction algorithm in CLC Genomics Workbench.](image)

This chapter explains how to visualize tracks, how to retrieve reference data and finally how to perform generic comparisons between tracks.

A track is the fundamental building block for NGS analysis in the CLC Genomics Workbench. The idea behind tracks is to provide a unified framework for the visualization, comparison and analysis of genome-scale studies such as whole-genome sequencing or exome resequencing projects and a variety of different -Seq data (i.e. RNA-seq, ChIP-Seq, DNAse-Seq).
In tracks, all information is tied to genomic positions. A central coordinate-system is provided by a reference genome, which allows different types of data or results for different samples to be seen and analyzed together.

Different types of data are represented in different types of tracks, and each type of track has its own particular editors. An example of a paired-end mapping read-track displaying reads and coverage is shown in figure 23.1.

Figure 23.1: A paired-end mapping read-track opened, displaying reads and coverage. Below the track, the button for creating a Track List is visible. On the right is the Side Panel.

### 23.1 Track types

The different track types in the **CLC Genomics Workbench** are:

**A sequence** This is the track type that is used for holding the reference genome. The sequence track contains the single reference sequences of the genome (e.g. the chromosomes or the consensus sequences of de novo assembled contigs).

**A reads track** This is the track type that is used for holding a read mapping e.g. as produced by the Map Reads to Reference (see section 25.1), Local Realignment (see section 25.3) or RNA-Seq Analysis (see section 28.1) tools. The reads track contains all the reads that have been mapped at their mapped positions, and you can zoom in all the way to base resolution. In case there are more reads than the height of the track allows, an overflow graph will be displayed above the reads in the same colors than the reads that it represents. When hovering over the reads, a vertical scroll bar will appear to the right of the reads to navigate through high coverage regions.

**A variant track** A variant track (see section 26.9.1) is a particular kind of track that is used to store features that fulfill the requirements for being a variant. A particular requirement for being a variant is that it refers to a particular region of the reference, and it is possible to describe exactly how the sample "Allele" sequence looks in this region, as compared to what the "reference allele" sequence looks like in this region. Variants may be of type SNV, MNV, replacement, insertion or deletion. A variant track may be produced either by running a Variant detection analysis (e.g using a variant detection tool or by importing a variant format file (such as a VCF or a GVF file) or downloading it from a database (e.g. dbSNP). The tool InDels and Structural Variants (see section 26.12) detects structural variants,
including insertions, deletions, inversions, translocations and tandem duplications. It will produce a variant track, which will contain some insertions and deletions (the "InDel" track). However, the tool will also detect some insertions for which the "Allele" sequence is not fully, but only partially, known. These insertions do not fulfill the requirements of being a variant and therefore cannot be put in the variant track. Instead they are put in the "SV track", along with the inversions and translocations. The "SV" track is an "annotation" (or "feature") track, which is less strict and more flexible, in the requirements to the types of annotations (or features) that it can contain (see below).

An annotation track (ulletin) Each annotation track contains a certain type of annotations. Examples are gene or mRNA tracks, which contain gene, respectively mRNA, annotations, UTR tracks, conservation score tracks and target region tracks. They may be obtained either by importing a BED, GTF or GFF file, or a database, such as ENSEMBL in the workbench using the Import Tracks tool (see section 6.2). Annotations tracks can also be downloaded with the Reference Data Manager. Also, many of the tools in the Workbench will output annotation tracks: for example, the Indels and Structural Variants tool will put the detected structural variants (that do not fulfill the requirements for being of type "variant") in an annotation track, or the ChIP-Seq detection tool which will compile the detected "peaks" into a "peak" annotation track. Finally, a gene (annotation) track can be created (see 23.5.1 Convert to Tracks). A description of how to annotate and filter tracks is found in section 23.6.

A coverage graph (bulletin) The coverage graph track is calculated from a reds track and contains a graphical display of the coverage at each position in the reference.

An expression track (bulletin) The RNA-seq algorithm produces expression tracks: one for genes and one for transcripts. These have an annotation for each gene or transcript, and an expression value associated to that annotation. The type of expression value associated with each annotation is determined by the expression value parameter selected in the RNA-Seq tool. These values are visualized as a color gradient from blue to red; the lowest expression value within each chromosome of the track is represented as 0% and the highest expression value within each chromosome of the track is represented by 100%.

An example of the different types of tracks is given in figure 23.2.

23.1.1 Visualizing, zooming and navigating tracks

Side Panel

The Side Panel is shown to the right of a track opened in the View Area (figure 23.3). The settings generally allow users to navigate the track using a specific position on a specific chromosome, to find a particular nucleotide sequence or annotation, and to change the text format.

In the Navigation section of the Track Side Panel, the upper field gives information about which chromosome is currently shown. The drop-down list can be used to jump to a different chromosome. The Location field displays the start and end positions of the shown region of the chromosome, but can also be used to navigate the track: enter a range or a single location point to get the visualization to zoom in the region of interest. It is also possible to enter the name of a chromosome (MT: or 5:), the name of a gene or transcript (BRCA" or DHFR-001), or even the range on a particular gene or transcript (BRCA2:122-124) Finally, the Overview drop-down menu defines what is shown above the track: cytobands, or cytobands with aggregated data. It can also be hidden all together.
CHAPTER 23. TRACKS

Figure 23.2: A track list containing different types of tracks. From the top: a sequence track, three annotation tracks with gene, mRNA and CDS annotations respectively, two variant tracks, a gene-level (GE) and a transcript level (TE) expression track, a coverage track and a reads track.

Additional settings specific to the type of track being open can be available. For example, you can change a Reads track layout as explained here: section 25.2.2. Similarly, when working with annotation tracks, the settings Track Layout | Labels controls where labels will be displayed in relation to the annotations (figure 23.4).

Figure 23.3: A CDS track with its Side Panel visible to the right.

Figure 23.4: The Side Panel for annotation tracks showing the Labels drop down menu.
Once you have changed the visualization of the track to your liking, it is possible to save the settings as described in section 4.6.

Additional tools

In a reads track, a vertical scroll bar will appear to the right of the reads when hovering on them to navigate through high coverage regions.

Specified tracks have buttons that will appear under the track name on the left side of the View Area (highlighted in figure 23.5): these buttons can be used to open the track as a table, or jump to the previous and next element.

![Figure 23.5: Hovering on a track will show additional buttons under the track name.](image)

Zooming

It is possible to zoom in and out in a track using the buttons in the lower right-hand corner of the View Area.

- to zoom in to 100% to see the data at base level, click the **Zoom to base level** icon.
- to zoom out to see all the data, click the **Zoom to Fit** icon.

When zooming out you will see that the data is visualized in an aggregated format using a density bar plot or a graph.

Navigation and zooming shortcuts

You can also use the zoom and scroll shortcuts described in the table below:
23.1.2 Showing a track in a table

All tracks containing annotations (including variants) can be opened in a table. It is usually helpful to open the table in split view so that both the track and the table can be seen at the same time. In particular, because track and table are connected, it becomes possible to navigate and zoom the track by selecting successively the different rows in the table. Similarly, making a selection in the track view will select the corresponding row in the table. Buttons in the variant table (figure 23.6) view can filter the table to show only the region selected in the track. One can also create a new track from the selected rows in the table.

Figure 23.6: Filter the table to display only the rows selected in the track using the menu highlighted in red. It is also possible to create a new track from the selected rows.
To open a track as a table in split view, press Ctrl (\(^{\text{⌘}}\) on Mac) while you click the table button at the bottom of the track view. You can also right-click on the track tab, and select "Show View | Table".

The table will have one row for each annotation, and the columns will reflect its information content. Figure 23.7 shows an example of a variant database track that is presented in a table.

![Figure 23.7: Showing a variant track in a table view.](image)

You can use the table to sort, filter and select annotations (see Appendix 3.3). Please note that there are two additional options for filtering on overlaps in the "Region" column.

When selecting a row in the table the graphical view will jump to this position on the genome. Please note that table filtering only affects the table. The track itself remains unaffected and keeps all annotations. If you also wish to filter tracks in the graphical view, the Annotate and Filter tools can be used instead.

At the bottom of the table a button labeled Create Track from Selection is available. This function can be used to create tracks showing only a subset of the data and annotations. Select the relevant rows in the table and click the button to create a new track that only includes the selected subset of the annotations. This function is particularly useful when used in combination with the filter.

### 23.2 Track lists

For details on how to find and import different tracks see section 6.2. Tracks are saved as files in the Navigation Area with specific icons representing each track type, e.g. an annotation track.

To visualize several tracks together, they can be combined into a Track List. Track lists can be created in different ways. One way is via the menu bar:

File | New | Track List

Another way is to use the Track Tool Create Track List. Finally, tracks can be created directly using the button labeled Create Track List that is found in the top right corner of the open track in the view area. Figure 23.8 shows an example of a track list including a track with mapped reads at the top, followed by a variant detection track, and in the lower part of the figure, the reference sequence with CDS annotations.

The track list is designed to be used as a container for multiple tracks for easy visualization and comparative analysis. Therefore all the involved tracks and the track list are required to be
present and located in one single location (Workbench or CLC Server). Otherwise, they will be marked as "Unresolved track" in the track list.

### 23.2.1 Adding, removing and reordering tracks

You can organize your tracks by dragging them up and down. Right-clicking on any of the tracks opens up a context menu with several options (Figure 23.9). The options shown in the context menu will vary depending on which tracks you have open in the viewing area. Hence, you may not be presented with all the options described here.

**Create Mapping Graph Tracks** This will allow you to create a new track from a mapping track (learn more in section 23.7).

**Find in Navigation Area** This will select the track in the Navigation Area.

**Open This Track** This opens a new view of the track. For annotation and variant tracks, a table view is opened as described in section 23.1.2. This can also be accomplished by double-clicking the track.

**Remove Track** This will remove the track from the current view. You can add it again by dragging it from the Navigation Area into the track list view or by pressing Undo (undo). 

**Include More Tracks** This will allow you to add other track sets to your current track set. Please note that the information in the track will still be stored in its original track set. This means that you by including a track in this way at the same time is adding a reference to this track.
in another track set. An example of this could be the inclusion of a SNP track from another sample to your current analysis.

### 23.2.2 Open track from a track list in table view

To open a table view of a track that is part of a track list, open the track list by double-clicking on the track name in the Navigation Area. The track will open in a graphical view. To open a single track from the track list in table view, either right-click on the track and choose "Open This Track" (see figure 23.10) or double-click on the name of the track you would like to open in table view (in the left side of the track when it is open in the View Area. This will automatically open the specific track in table view.

![Figure 23.10: One way to open a table view of a track that is part of a track list is to right click on the track of interest and select "Open This Table".](image)

### 23.2.3 Finding annotations on the genome

In the Side Panel under Find, a search field allows you to quickly find the annotation that you are looking for. The list of tracks further allows you to restrict the search to a particular track (e.g. a gene track).

In the search field you can enter any kind of text that exists in the annotation track. As an example, consider the gene and tool tip shown in figure 23.11.

This gene could be found by searching for the name specifically or, by using a wildcards (asterisks), less specific search terms could be use, giving more flexibility. To find BRCA2, for example, any of the following entries could be typed in the search field:

**BRCA2** This would match the annotation name exactly.
**BRCA** This would match the annotation name as well as other genes with a text starting with BRCA (e.g. the BRCA1 gene).

**RCA2** This would match the annotation name as well as other genes with a text ending with RCA2 (e.g. the SMARCA2 gene).

**600185** This would match the db_xref qualifier for the OMIM database. All the text shown for the annotation in figure 23.11 can be searched this way, both as exact matches and with the * before or after the search term.

Just below the search field in the **Side Panel**, a status label informs about the progress of the search and the hit that has been found. Placing the mouse on top of the label will display a tooltip with more info (see 23.12).

The search will be performed throughout the entire genome beginning with the chromosome currently shown and stopping when it finds the first hit. Press **Find** again to find the next hit. Once the whole genome has been traversed, the status will inform you that you have searched the whole genome. Click the **Find** button to start the search again.

Please note that you can also use the table view of an annotation track to perform more advanced queries of the data. When clicking on the annotation of interest in the table, the track list will zoom to that annotation.

Hovering the mouse cursor over an annotation in the track will display (figure 23.13):

- in the View Area, a tooltip with information about the annotation.
Figure 23.13: When hovering on an annotation in a track view, relevant information about this annotation can be found in three different locations of the workbench.

- in the ruler at the top of the Track list view: the position of the mouse cursor relative to the reference, the name of the annotation, the strand of the annotation, which exon is currently being hovered over, and the location of the mouse cursor relative to the annotation start (ignoring introns).
- in the lower right corner of the workbench, the annotation type, the relative position of the mouse cursor in the annotation, the strand, and the location of the mouse cursor in the reference.

23.2.4 Extract sequences from tracks

Like for all other sequence lists (see section 14.2), it is possible to extract sequences from tracks.

The sequence of interest can be selected by dragging the mouse over the region of interest, followed by a right click on the reads (or on the sequence in the case of a sequence track) and a click on Extract sequence(s) (figure 23.14).

In case of a reference sequence track included in a Track List, the pop up window will suggest to Extract annotations, which will extract all the annotations present on the other tracks of the Track list, and add them to the extracted sequence. This option is disabled when the reference sequence is not part of a Track List.

In case of a read mapping, this opens up the dialog shown in figure 23.15 that allows specification of whether the selected sequences should be extracted as single sequences or as a list of sequences.

Right clicking on the reads also enable the option Extract from selection, a function that corresponds to the Extract from selection described in section 18.7.6 although with small
CHAPTER 23. TRACKS

Figure 23.14: Extract sequences from a read mapping track.

Figure 23.15: Select destination for extracted sequences.

differences. Common for both versions of the Extract from selection function is that when extracting reads in an interval, only reads that are completely covered by the selection will be part of the extracted sequence, which in turn means that the tool can be used to extract only a subset of reads.

Clicking Extract from selection opens up the dialog shown in figure 23.16.

The purpose of this dialog is to let you specify which kinds of reads you wish to include. Per default all reads are included.

The options are:

**Interval**

- **Only include reads contained within the intervals** Only reads that are included within the selection will be extracted. Reads that continue outside the selected area are not included.

**Paired status**

- **Include intact paired reads** When paired reads are placed within the paired distance specified, they will fall into this category. Per default, these reads are colored in blue.

- **Include paired reads from broken pairs** When a pair is broken, either because only one read in the pair matches, or because the distance or relative orientation is wrong, the reads are placed and colored as single reads, but you can still extract them by checking this box.
Include single reads  This will include reads that are marked as single reads (as opposed to paired reads). Note that paired reads that have been broken during assembly are not included in this category. Single reads that come from trimming paired sequence lists are included in this category.

**Match specificity**

Include specific matches  Reads that only are mapped to one position.

Include non-specific matches  Reads that have multiple equally good alignments to the reference. These reads are colored yellow per default.

**Alignment quality**

Include perfectly aligned reads  Reads where the full read is perfectly aligned to the reference sequence (or consensus sequence for de novo assemblies). Note that at the end of the contig, reads may extend beyond the contig (this is not visible unless you make a selection on the read and observe the position numbering in the status bar). Such reads are not considered perfectly aligned reads because they don’t align in their entire length.

Include reads with less than perfect alignment  Reads with mismatches, insertions or deletions, or with unaligned nucleotides at the ends (the faded part of a read).

**Spliced status**

Include spliced reads  Reads that are across an intron.

Include non spliced reads  Reads that are not across an intron.

23.2.5 Creating track lists in workflows

Track lists can be created as part of workflows. Track lists are different from all other workflow outputs in the sense that the tracks inside the track lists have to be saved separately, even if
they are included in a track list.

Figure 23.17 shows an example of a workflow where two tracks are fed into the Create Track List element.

![Workflow Diagram]

Figure 23.17: *This workflow does not work because the two tracks need to be marked as output.*

In the left hand side example, there is a warning at the bottom of the editor pointing at the fact that these two tracks need to be selected as output in order for the workflow to be validated. To the right, the workflow has been corrected by selecting the tracks as output, and the workflow can now be executed.

### 23.3 Retrieving reference data tracks

For most applications (except de novo sequencing), you will need reference data in the form of a reference genome sequence, annotations, known variants etc. There are three basic ways of obtaining reference data tracks:

1. Use the integrated tool for downloading reference genomes as tracks (see section 8.1).
2. Import tracks from files (see section 6.2).
3. Convert sequences with annotations to tracks (learn more in section 23.5). Sequences can come from a variety of sources:
   - **Standard Import**  
     The standard import accepts common data formats like fasta, genbank etc. (learn more in section 6)
   - **Downloading from NCBI**  
     The integrated tool for searching and downloading data from NCBI (learn more in section 7.1).
   - **Contigs created from de novo assembly.**  
     Contig sequences from de novo assembly (see section 30.2) can be considered a reference genome for e.g. subsequent resequencing analysis applications.

Please note that tracks are not yet supported with all transcriptomics tools of CLC Genomics Workbench. In this case, you have to provide standard sequences (downloading from NCBI or importing files).
23.4 Merge Annotation Tracks

Two tracks can be merged using the **Merge Annotation Tracks** tool:

Toolbox | Track Tools | Merge Annotation Tracks

Select two or more tracks to be merged. The tracks have to be of the same type, e.g. gene tracks, and be based on the same genome.

Click **Next** and **Finish** to merge the tracks.

If the same annotation is found in both tracks, it is merged into one. If the two annotations share the same region (i.e. same coordinates), they are merged. Information from both annotations are retained in the output. Annotations are merged even when their names differ. Which name is being kept is entirely based on the order of the input tracks as the name being kept is derived from the track that was selected first in the **Merge Read Mappings** wizard. An extra column labeled **Origin tracks** is added to the resulting track indicating which track the annotation originates from. The Merging Annotation Tracks tool is useful when merging gene tracks from different sources using different naming conventions.

Please note that this tool is not well-suited for comparing tracks (see section 27.4 instead).

23.5 Track Conversion

The **CLC Genomics Workbench** provides tools for converting data to tracks, for extracting sequences and annotations from tracks, and for creating standard annotated sequences and mappings.

23.5.1 Convert to Tracks

When working with tracks, information from standard sequences and mappings are split into specialized tracks with sequence, annotations and reads. This tool creates a number of tracks based on the input sequences:

Toolbox | Track Tools | Track Conversion | Convert to Tracks

The following kinds of data can be converted to tracks: nucleotide sequences, sequence lists and read mappings. Select the input and click **Next** to specify which tracks should be created (see figure 23.18).

![Figure 23.18: Converting data to tracks.](image-url)
CHAPTER 23. TRACKS

For sequences and sequence lists, you can **Create a sequence track** (for mappings, this will be the reference sequence) and a number of **Annotation tracks**. For each annotation type selected, a track will be created. For mappings, a **Reads track** can be created as well.

At the bottom of the dialog, there is an option to sort sequences by name. This is useful for example to order chromosomes in the menus etc (chr1, chr2, etc). Alphanumerical sorting is used to ensure that the part of the name consisting of numbers is sorted numerically (to avoid e.g. chr10 getting in front of chr2). When working with de novo assemblies with huge numbers of contigs, this option will require additional memory and computation time.

### 23.5.2 Convert from Tracks

Tracks are useful for comparative analysis and visualization, but sometimes it is necessary to convert a track to a normal sequence or mapping. This can be done with the **Convert from Tracks** tool that can be found here:

![Toolbox | Track Tools ( ) | Track Conversion | Convert from Tracks](image)

One or more tracks can be used as input. In the example given in figure 23.19 a reads track and two annotation tracks are converted simultaneously to an annotated read mapping (figure 23.20).

![Figure 23.19: A reads track and two annotation tracks are converted from track format to stand-alone format.](image)

Likewise it is possible to create an annotated, stand-alone reference from a reference track and the desired number of annotation tracks. This is shown in figure 23.21 where one reference and two annotation tracks are used as input.

The output is shown in figure 23.22. The reference sequence has been transformed to stand-alone format with the two annotations "CDS" and "Gene".

Depending on the input provided, the tool will create one of the following types of output:

- **Sequence** ( ) Will be created when a sequence track ( ) with a genome with only one sequence (one chromosome) is provided as input

- **Sequence list** ( ) Will be created when a sequence track ( ) with a genome with several sequences (several chromosomes) is provided as input

- **Mapping** ( ) Will be created when a reads track ( ) with a genome with only one sequence (one chromosome) is provided as input.
Figure 23.20: The upper part of the figure shows the three individual input tracks, arranged for simplicity in a track list. The lower part of the figure shows the resulting stand-alone annotated read mapping.

Figure 23.21: A reference track and two annotation tracks are converted from track format to stand-alone format.

**Mapping table** Will be created when a reads track with a genome with several sequences (several chromosomes) is provided as input.

In all cases, any number of annotation tracks can be provided, and the annotations will be added to the sequences (reference sequence for mappings) as shown in figure 23.20.

### 23.6 Annotate and Filter

One of the big advantages of using tracks is that tracks support comparative analysis between different kinds of data. This section describes generic tools for annotating and filtering tracks (for filtering and annotating variants, please refer to chapter 27).
23.6.1 Annotate with Overlap Information

The tool Annotate with Overlap Information will create a copy of the track used as input and add information from overlapping annotations or variants.

To start the tool, go to:

Toolbox | Track Tools | Annotate and Filter | Annotate with Overlap Information

First, select the track you wish to annotate and click Next. You can choose variants tracks, expression tracks or statistical comparison tracks as input. Next, select the variant track to be used for overlap comparison. The requirement for being registered as an overlap is that parts of the annotations are overlapping, regardless of the strandedness of the annotations: this makes it unsuitable for comparing two gene tracks, but great for annotating variants with overlapping genes or regulatory regions.

It is possible to "Keep only one copy of duplicate annotations" by leaving the option checked as it is by default (see figure 23.23).
The result of this tool is a new track with all the annotations from the input track and with additional information from the annotations that overlap from the other track. Annotations are visible in the tooltips that appears when hovering the mouse on a variant in the Track view, or as additional columns in the Table view of the track.

### 23.6.2 Filter Annotations on Name

The name filter allows you to use a list of names as input to create a new track only with these names. This is useful if you wish to filter your variants so that only those within certain genes are reported.

The proposed workflow would be to first create a new gene track only containing the genes of interest. This is done using this tool. Next, use the filter from the overlapping annotations tool (see section 23.6.3) to filter the variants based on the track with genes of interest.

**Toolbox | Track Tools | Annotate and Filter | Filter Annotations on Name**

Select the track you wish to filter and click **Next**.

![Figure 23.24: Specify names for filtering.](image)

As shown in figure 23.24, you can specify a list of annotation names. Each name should be on a separate line.

In the bottom part of the wizard you can choose whether you wish to keep the annotations that are found, or whether you wish to exclude them. In the use case described above a track was created with only those annotations being kept that matched the specified names. Sometimes the other option may be useful, for example if you wish to screen certain categories of genes from the analysis (for example excluding all cancer genes).

### 23.6.3 Filter Based on Overlap

The overlap filter will be used for filtering an annotation track based on an overlap with another annotation track. This can be used to e.g. only show variants that fall within genes or regulatory regions or for restricting variants results to only cover a subset of genes as explained in section 23.6.2. Please note that for comparing variant tracks, more specific filters should be used (see section 27.2.2).
If you are just interested in finding out whether one particular position overlaps any of the annotations, you can use the advanced table filter and filter on the region column (track tables are described in section 23.1.2).

Toolbox | Track Tools | Annotate and Filter | Filter Based on Overlap

Select the track you wish to filter and click Next to specify the track of overlapping annotations (see figure 23.25).

![Figure 23.25: Select overlapping annotations track.](image)

Next, select the track that should be used for comparison and tick whether you wish to keep annotations that overlap, or whether to keep annotations that do not overlap with the track selected. An overlap has a simple definition – if the annotation used as input has at least one shared position with the other track, there is an overlap. The boundaries of the annotations do not need to match.

## 23.7 Graphs

Graphs can be a good way to quickly get an overview of certain types of information. This is the case for e.g. the GC content in a sequence or the read coverage. The CLC Genomics Workbench offers two different tools that can create graph tracks from either a sequence or a read mapping. The two available tools are:

- Create GC Content Graph
- Create Mapping Graph

Both tools are found in the toolbox:

Toolbox | Track Tools | Graphs

Graph tracks can also be created directly from the track view or track list view by right-clicking the track you wish to use as input, which will give access to the toolbox.

To understand what graph tracks are, we will look at an example. We will use the Create GC Content Graph tool to go into detail with one type of graph tracks.
23.7.1 Create GC Content Graph

The Create GC Content Graph tool needs a sequence track as input and will create a graph track with the GC contents of that sequence.

To run the tool go to the toolbox:

Toolbox | Track Tools ( ) | Graphs | Create GC Content Graph

Select the sequence track that should be used as input (see figure 23.26).

In the next wizard step (see figure 23.27), you can specify the window size, i.e., the size of the window around the central base in the region that is used to calculate the GC content. This number must be odd as you need a central base and an equal number of bases to each side of the central base. For example, with a window size of 25, the GC content for the central base will be calculated based on the nucleotide composition in the central base and the 12 bases upstream and 12 bases downstream of the central base.

Click on the button labeled Next, choose to save your results, and click on the button labeled Finish. The output can be seen in figure 23.28. The output from "Create GC Content Graph" is a graph track. The graph track shows one value for each base with one graph being available for each chromosome. When zoomed out as shown in this figure, three different graphs with three different colors can be seen. The top graph with the darkest blue color represents the maximum observed GC content values in the specific region, the graph in the middle with the intermediate blue color shows the mean observed GC content values in the specific region, and the graph at the bottom with the light blue color shows the minimum observed GC content values in the specific region.

When zooming all the way in to single nucleotide level only one graph can now be seen as you are now no longer looking at large genomic regions. Instead, you can now use the tooltip by mousing over each individual base to look at the GC content for that particular base and the number of bases that you specified as the window size to be used. This is shown in figure 23.29 where the
CHAPTER 23. TRACKS

Figure 23.28: The output from "Create GC Content Graph" is a graph track. The graph track shows one value for each base with one graph being available for each chromosome. The top part of the figure shows the graph track when zoomed all the way out and the bottom part of the figure shows a track list with the sequence track that was used as input together with the output graph track. The input and the output tracks were combined in one view as a track list (see section 23.2) by clicking on the button labeled Create Track List found in the upper right corner of the graph track in the top part of the figure (see the red arrow).

Figure 23.29: The top part of the figure shows the graph track when zoomed all the way out. The bottom part of the window shows a graph track together with the input genomic sequence at single nucleotide resolution. By mousing over one nucleotide, you can see the GC content for this position. In our example we chose a window size of 25 nucleotides and the GC content that is shown for one nucleotide is the GC content for the central nucleotide and the 12 bases upstream and downstream of this nucleotide.

23.7.2 Create Mapping Graph

The Create Mapping Graph tool can create a range of different graphs from a read mapping track. To run the tool go to the toolbox:

Toolbox | Track Tools ( ) | Graphs | Create Mapping Graph

Select the read mapping as shown in figure 23.30 and click on the button labeled Next.

Select the graph tracks that you would like to create.
CHAPTER 23. TRACKS

Figure 23.30: Creating graph track from mappings.

One graph track output will be created for each of the graph tracks you have chosen by checking the boxes shown in figure 23.31.

Figure 23.31: Choose the types of graph tracks you would like to generate.

The following options exist:

- Read coverage. For each position this graph shows the number of reads contributing to the alignment (see a more elaborate definition in section 27.1.2).

- Non-specific read coverage. Non-specific reads are reads that would fit equally well other places in the reference genome.

- Unaligned ends coverage. Un-aligned ends arise when a read has been locally aligned to a reference sequence, and then end of the read is left unaligned because there are mismatches or gaps relative to the reference sequence. This part of the read does not contribute to the read coverage above. The unaligned ends coverage graph shows how many reads that have unaligned ends at each position.

- Non-perfect read coverage. Non-perfect reads are reads with one or more mismatches or gaps relative to the reference sequence.

- Paired read coverage. This lists the coverage of intact pairs. Coverage is counted as one in the overlapping region.

- Paired end distance. Displays the average distance between the forward and the reverse read in a pair.
- Broken pair coverage. A pair is broken either because only one read in the pair matches, or because the distance or relative orientation between the reads is wrong.

- Reads start coverage. For each position this graph shows the number of reads that start in that position.

Click on the button labeled Next, choose where to save the generated output(s) and click on the button labeled Finish.

An example of three different outputs is shown in figure 23.32.

![Figure 23.32: Three types of graph tracks are shown.](image)

Note that the option "Fix graph bounds" found under Track layout in the Side Panel is useful to manually adjust the numbers on the y-axis.

When zoomed out, the graph tracks are composed of three curves showing the maximum, mean, and minimum value observed in a given region (see figure 23.35). When zoomed in all the way down to base resolution only one curve will be shown reflecting the exact observation at each individual position (figure 23.33).

![Figure 23.33: A graph track zoomed in.](image)

### 23.7.3 Identify Graph Threshold Areas

The Identify Graph Threshold Areas tool uses graph tracks as input to identify graph regions that fall within certain limits or thresholds. Both a lower and an upper threshold can be specified to create an annotation track for those regions of a graph track where the values are in the given range (see figure 23.34). The range chosen for the lower and upper thresholds will depend on the data (coverage, quality etc).

The `window-size` parameter specifies the width of the window around every position that is used to calculate an average value for that position and hence "smoothes" the graph track beforehand. A window size of 1 will simply use the value present at every individual position and determine if it is within the upper and lower threshold. In contrast, a window size of 100 checks if the average value derived from the surrounding 100 positions falls between the minimum and maximum
threshold. Such larger windows help to prevent "jumps" in the graph track from fragmenting the output intervals or help to detect over-represented regions in the track that are only visible when looked at in the context of larger intervals and lower resolution.

It is also possible to restrict the tool to certain regions with specifying a region track.

An example output is shown in figure 23.35 where the coverage graph has some local minima. However, by using the averaging window, the tool is able to produce a single unbroken annotation covering the entire region. Of course larger window sizes result in regions that are broader and hence their boundaries are less likely to exactly coincide with the borders of visually recognizable borders of regions in the track.

Figure 23.34: Specification of lower and upper thresholds.
Figure 23.35: Track list including a read coverage graph, a reads track, and two read graph threshold graphs generated to annotate regions where the coverage was above 100. The top track graph threshold was generated with a window size of 1, while the one from below was generated with a window size of 150.

24.1 QC for Sequencing Reads

Quality assurance as well as concern regarding sample authenticity in biotechnology and bioengineering have always been serious topics in both production and research. While next generation sequencing techniques greatly enhance in-depth analyses of DNA-samples, they, however, introduce additional error-sources. Resulting error-signatures can neither be easily removed from resulting sequencing data nor even recognized, which is mainly due to the massive amount of data. Altogether biologists and sequencing facility technicians face not only issues of minor relevance, e.g. suboptimal library preparation, but also serious incidents, including sample-contamination or even mix-up, ultimately threatening the accuracy of biological conclusions.

Unfortunately, most of the problems and evolving questions raised above can’t be solved and answered entirely. However, the sequencing data quality control tool of the CLC Genomics Workbench provides various generic tools to assist in the quality control process of the samples by assessing and visualizing statistics on:

- Sequence-read lengths and base-coverages
This tool aims at assessing above quality-indicators and investigates proper and improper result presentation. The inspiration comes from the FastQC-project (http://www.bioinformatics.babraham.ac.uk/projects/fastqc/).

Note that currently, adapter contamination, i.e., adapter sequences in the reads, cannot be detected in a reliable way with this tool. In some cases, adapter contamination will show up as enriched 5-mers near the end of sequences but only if the contamination is severe.

The tool is found in the Toolbox:

Toolbox | Prepare Sequencing Data | QC for Sequencing Reads

Select one or more sequence lists with sequencing reads as input. If sequence lists in the Navigation Area were already selected, these will be shown in the Selected Elements window. When multiple lists are selected as an input, they are all analyzed in one pool. If you need separate reports for each data set, you can run it in a batch. Click **Next** to adjust output options which allow you to select the graphical and supplementary report.

The report comes in two different flavors: a supplementary report consisting of tables representing all the values that are calculated, and a main summary graphical report where the tables are visualized in plots (see an example in figure 24.1). Both reports can be exported as pdf files or Excel spread sheets.

![Quality distribution](image)

**Figure 24.1:** An example of a plot from the graphical report, showing the quality values per base position.

The Summary table provides information regarding the creation date, the author, the software used, the number of data sets the report is based upon, as well as data name and content in terms of read number and total number of nucleotides. The report is then divided in per-sequence and
per-base analyses. In the per-sequence analyses, some characteristic (a single value) is assessed for each sequence and then contributes to the overall assessment. In per-base assessments each base position is examined and counted independently. In both sections, the first items assess the most simple characteristics that are supported by all sequencing technologies while the quality analyses examine quality scores reported from technology-dependent base callers. Please note that the NGS import tools of the CLC Genomics Workbench and CLC Genomics Server convert quality scores to PHRED-scale, regardless of the data source.

24.1.1 Per-sequence analysis

Lengths distribution Counts the number of sequences that have been observed for individual sequence lengths. The resulting table correlates sequence-lengths in base-pairs with numbers of sequences observed with that number of base-pairs. The length distribution depends on your library preparation and sequencing protocol. If you observe secondary peaks at unexpected lengths you may want to consider removing these. Using the Workbench Trim tool you can trim away reads above and/or below a certain length.

GC-content distribution Counts the number of sequences that feature individual %GC-contents in 101 bins ranging from 0 to 100%. The %GC-content of a sequence is calculated by dividing the absolute number of G/C-nucleotides by the length of that sequence, and should look like a normal distribution in the range of what is expected for the genome you are working with. If the GC-content is substantially lower (the normal distribution is shifted to the left), it may be that GC-rich areas have not been properly covered. You can check this by mapping the reads to your reference. A non-normal distribution, or one that has several peaks indicates the presence of contaminants in the reads.

Ambiguous base content Counts the number of sequences that feature individual %N-contents in 101 bins ranging from 0 to 100%, where N refers to all ambiguous base-codes as specified by IUPAC. The %N-content of a sequence is calculated by dividing the absolute number of ambiguous nucleotides through the length of that sequence. This distribution should be as close to 0 as possible.

Quality distribution Calculates the amount of sequences that feature individual PHRED-scores in 64 bins from 0 to 63. The quality score of a sequence as calculated as arithmetic mean of its base qualities. PHRED-scores of 30 and above are considered high quality. If you have many reads with low quality you may want to discuss this with your sequencing provider. Low quality bases/reads can also be trimmed off with the Trim Reads tool.

24.1.2 Per-base analysis

Coverage Calculates absolute coverages for individual base positions. The resulting graph correlates base-positions with the number of sequences that supported (covered) that position.

Nucleotide contributions Calculates absolute coverages for the four DNA nucleotides (A, C, G or T) for each base position in the sequences. In a random library you would expect little or no difference between the bases, thus the lines in this plot should be parallel to each other. The relative amounts of each base should reflect the overall amount of the bases in your genome. A strong bias along the read length where the lines fluctuate a lot for certain positions may indicate that an over-represented sequence is contaminating your
sequences. However, if this is at the 5’ or 3’ ends, it will likely be adapters that you can remove using the Trim Reads tool.

**GC-content** Calculates absolute coverages of C’s + G’s for each base position in the sequences. If you see a GC bias with changes at specific base positions along the read length this could indicate that an over-represented sequence is contaminating your library.

**Ambiguous base-content** Calculates absolute coverages of N’s, for each base position in the sequences, where N refers to all ambiguous base-codes as specified by IUPAC.

**Quality distribution** Calculates the amount of bases that feature individual PHRED-scores in 64 bins from 0 to 63. This results in a three-dimensional table, where dimension 1 refers to the base-position, dimension 2 refers to the quality-score and dimension 3 to amounts of bases observed at that position with that quality score. PHRED-scores above 20 are considered good quality. It is normal to see the quality dropping off near the end of reads. Such low-quality ends can be trimmed off using the Trim Reads tool.

### 24.1.3 Over-representation analyses

**Enriched 5-mer distribution** The 5-mer analysis examines the enrichment of penta-nucleotides. The enrichment of 5-mers is calculated as the ratio of observed and expected 5-mer frequencies. The expected frequency is calculated as product of the empirical nucleotide probabilities that make up the 5-mer. (Example: given the 5-mer = CCCCC and cytosines have been observed to 20% in the examined sequences, the 5-mer expectation is $0.2^5$). Note that 5-mers that contain ambiguous bases (anything different from A/T/C/G) are ignored. This analysis calculates the absolute coverage and enrichment for each 5-mer (observed/expected based on background distribution of nucleotides) for each base position, and plots position vs enrichment data for the top five enriched 5-mers (or fewer if less than five enriched 5-mers are present). It will reveal if there is a bias at certain positions along the read length. This may originate from non-trimmed adapter sequences, poly A tails and more.

**Sequence duplication levels** The duplicated sequences analysis identifies sequence reads that have been sequenced multiple times. A high level of duplication may indicate an enrichment bias, as for instance introduced by PCR amplification. Please note that multiple input sequence lists will be considered as one federated data set for this analysis. Batch mode can be used to generate separate reports for individual sequence lists.

In order to identify duplicate reads the tool examines all reads in the input and uses a clone dictionary containing per clone the read representing the clone and a counter representing the size of the clone. For each input read these steps are followed: (1) check whether the read is already in the dictionary. (2a) if yes, increment the according counter and continue with next read. (2b) if not, put the read in the dictionary and set its counter to 1.

To achieve reasonable performance, the dictionary has a maximum capacity of 250,000 clones. To this end, step 2a involves a random decision as to whether a read is granted entry into the clone dictionary. Every read that is not already in the dictionary has the same chance $T$ of entering the clone dictionary with $T = 250,000 / \text{total amount of input reads}$. This design has the following properties:

- The clone dictionary will ultimately contain at most 250,000 entries.
• The sum of all clone sizes in the dictionary amounts at most to the total number of input reads.

• Because of $T$ being constant for all input reads, even a cluster of reads belonging to the same clone and first occurring towards the end of the input can be detected.

• Because of the random sampling, the tool might underestimate the size of a read clone, specifically if its first read representative does not make it into the dictionary. The ratio is that a larger clone has a higher cumulative chance of being eventually represented in the dictionary than a smaller clone.

Because all current sequencing techniques tend to report decreasing quality scores for the 3’ ends of sequences, there is a risk that duplicates are NOT detected, merely because of sequencing errors towards their 3’ ends. The identity of two sequence reads is therefore determined based on the identity of the first 50nt from the 5’ end.

The results of this analysis are presented in a plot and a corresponding table correlating the clone size (duplication count) with the number of clones of that size. For example, if the input contains 10 sequences and each sequence was seen exactly once, then the table will contain only one row with duplication-count=1 and sequence-count=10. Note: due to space restrictions the corresponding bar-plot shows only bars for duplication-counts of $x=[0-100]$. Bar-heights of duplication-counts >100 are accumulated at $x=100$. Please refer to the table-report for a full list of individual duplication-counts.

Duplicated sequences This results in a list of actual sequences most prevalently observed. The list contains a maximum of 25 (most frequently observed) sequences and is only present in the supplementary report.

24.2 Trim Reads

CLC Genomics Workbench offers a number of ways to trim your sequence reads prior to assembly and mapping, including adapter trimming, quality trimming and length trimming. For each original read, the regions of the sequence to be removed for each type of trimming operation are determined independently according to choices made in the trim dialogs. The types of trim operations that can be performed are:

1. Quality trimming based on quality scores
2. Ambiguity trimming to trim off stretches of Ns for example
3. Adapter trimming (automatic, or also with a Trim Adapter List, see section 24.2.2)
4. Base trim to remove a specified number of bases at either 3’ or 5’ end of the reads
5. Length trimming to remove reads shorter or longer than a specified threshold

The trim operation that removes the largest region of the original read from either end is performed while other trim operations are ignored as they would just remove part of the same region.

Note that this may occasionally expose an internal region in a read that has now become subject to trimming. In such cases, trimming may have to be done more than once.
The result of the trim is a list of sequences that have passed the trim (referred to as the trimmed list below) and optionally a list of the sequences that have been discarded and a summary report (list of discarded sequences). The original data will not be changed.

To start trimming:

Toolbox | Prepare Sequencing Data | Trim Reads

This opens a dialog where you can add sequences or sequence lists. If you add several sequence lists, each list will be processed separately and you will get a list of trimmed sequences for each input sequence list.

When the sequences are selected, click Next.

24.2.1 Quality trimming

This opens the dialog displayed in figure 24.2 where you can specify parameters for quality trimming.

The following parameters can be adjusted in the dialog:

- **Trim using quality scores.** If the sequence files contain quality scores from a base caller algorithm this information can be used for trimming sequence ends. The program uses the modified-Mott trimming algorithm for this purpose (Richard Mott, personal communication): Quality scores in the Workbench are on a Phred scale, and formats using other scales will be converted during import. The Phred quality scores \( Q \), defined as: 
  \[
  Q = -10 \log_{10}(P),
  \]
  where \( P \) is the base-calling error probability, can then be used to calculate the error probabilities, which in turn can be used to set the limit for, which bases should be trimmed.

Hence, the first step in the trim process is to convert the quality score \( Q \) to an error probability: 
  \[
  p_{\text{error}} = 10^{-Q/10}.
  \] (This now means that low values are high quality bases.)

Next, for every base a new value is calculated: 
  \( \text{Limit} - p_{\text{error}} \). This value will be negative for low quality bases, where the error probability is high. For every base, the Workbench calculates the running sum of this value. If the sum drops below zero, it is set to zero. The part of the sequence not trimmed will be the region ending at the highest value of the running sum and starting at the last zero value before this highest score. Everything before and after this region will be trimmed. A read will be completely removed if the score never makes it above zero.

- **Trim ambiguous nucleotides.** This option trims the sequence ends based on the presence of ambiguous nucleotides (typically N). Note that the automated sequencer generating the
data must be set to output ambiguous nucleotides in order for this option to apply. The algorithm takes as input the maximal number of ambiguous nucleotides allowed in the sequence after trimming. If this maximum is set to e.g. 3, the algorithm finds the maximum length region containing 3 or fewer ambiguities and then trims away the ends not included in this region. The "Trim ambiguous nucleotides" option trims all types of ambiguous nucleotides (see Appendix G).

24.2.2 Adapter trimming

Clicking Next will allow you to specify parameters for adapter trimming.

When you are analyzing sequencing data, the adapters must be trimmed off before you proceed with further analysis. The removal of adapters is often done directly on the sequencing machine, but in some cases, some adapters remain on the sequenced reads. The presence of remaining adapters can lead to misleading results, so we recommend to trim them off the reads (figure 24.3).

Figure 24.3:Trimming your sequencing data for adapter sequences.

The default option for this trimming step is to use the "Automatic read-through adapter trimming", which will detect read-through adapter sequence on paired-end reads automatically. Read-through means that the sample DNA fragment being sequenced is shorter than the read length, such that the 3' end of one read includes the reverse-complement of the adapter from the start of the other read. Leaving this option enabled is always recommended: the trimming performed automatically can detect read-through of even a single nucleotide, which is not the case when trimming using a trim adapter list. The detected adapters for the first and second read can be found in the Trim Reads report.

There are however a couple of limitations on the "Automatic read-through adapter trimming" option: this option detects overlap in paired reads containing standard nucleotides (A, T, C, and G). If the read contains ambiguous symbols, such as N, these will not match the standard nucleotides.

Also, the first and second read should be of equal (or near-equal) length - some sequencing protocols use asymmetric read lengths for the first and second read, in which case the tool is less likely to detect and trim the read-through.

So when you are working with data of low quality, asymmetric read lengths, mate-paired reads, single reads, small RNAs, or also when working with gene specific primers, it is recommended that you specify a trim adapter read in addition to using the "Automatic read-through adapter
trimming” option. It is even possible to use the report of the Trim Read tool to find out what Trim adapter list should be used for the data at hand. Read section 24.2.3 to learn how to create an adapter list.

Below you find a preview listing the results of trimming with the adapter trimming list on 1000 reads in the input file (reads 1001-2000 when the read file is long enough). This is useful for a quick feedback on how changes in the parameters affect the trimming (rather than having to run the full analysis several times to identify a good parameter set). The following information is shown:

- **Name.** The name of the adapter.
- **Matches found.** Number of matches found based on the settings.
- **Reads discarded.** This is the number of reads that will be completely discarded. This can either be because they are completely trimmed (when the **Action** is set to Remove adapter and the match is found at the 3’ end of the read), or when the **Action** is set to Discard when found or Discard when not found.
- **Nucleotides removed.** The number of nucleotides that are trimmed include both the ones coming from the reads that are discarded and the ones coming from the parts of the reads that are trimmed off.
- **Avg. length.** This is the average length of the reads that are retained (excluding the ones that are discarded).

Note that the preview panel is only showing how the trim adapter list will affect the results. Other kinds of trimming (automatic trimming of read-through adapters, quality or length trimming) are not reflected in the preview table.

### 24.2.3 Trim adapter list

The Trim Reads tool is set by default to detect automatically read-through adapters present in the reads used as input for the tool. We recommend to always enable this option. In addition, you can use a Trim adapter list for a more thorough trimming of read-through adapter in reads of lower quality, or to trim for specific adapters that are not read-through such as small RNAs, gene specific primers, or when working with single or mate-paired reads. In such cases, you have to import or create a Trim adapter list that must be supplied to the Trim Reads tool.

**Creating a new Trim adapter list**

It is possible to generate a Trim adapter list directly in the workbench. Go to:

**File | New | Trim Adapter List**

This will create a new empty Trim adapter list. At the bottom of the view, you have the following options that allow you to edit the Trim adapter list:

- **Add Rows.** Add a new adapter.
- **Edit Row.** Edit the selected adapter. This can also be achieved by double-clicking the relevant row in the table.
• Delete Row. Delete the selected adapter.

Add the adapter(s) that you would like to use for trimming by clicking on the button Add Row (➕) found at the bottom of the View Area. Adding an adapter is done in two steps. In the first wizard step (figure 24.4), you enter the basic information about the adapter, and how the trimming should be done relative to the adapter found.

![Figure 24.4: Add an adapter to the Trim Adapter List by clicking on the button labeled "Add Row" found at the bottom of the New Trim Adapter view.](image)

In the second dialog (figure 24.5), you define the scores that will be used to recognize adapters. For each read sequence in the input, a Smith-Waterman alignment [Smith and Waterman, 1981] is carried out with each adapter sequence. Alignment scores are computed and compared to the minimum scores provided for each adapter when setting up the Trim adapter List. If the alignment score is higher or equal to the minimum score, the adapter is recognized and the trimming can happen as specified in the first wizard. If however the alignment score is lower than the minimum score, the adapter is not recognized and trimmed.

**Trim adapter**

Start by providing the name and sequence of the adapter that should be trimmed away. Use the Reverse Complement button to reverse complement the sequence you typed in if it is found in reverse complement in the reads. You can then specify whether you want the adapter to be trimmed on all reads, or more specifically on the first or second read of a pair.

**When an adapter is found**

Once you have entered the sequence of the adapter, a visual shows how the adapter will be
Figure 24.5: Set the scoring used to define what will be considered as adaptor.

trimmed, allowing you to decide which option suits your needs best:

- Remove the adapter and preceding sequence (5’ trim)
- Remove the adapter and following sequence (3’ trim)
- Discard the read. The read will be placed in the list of discarded sequences. This can be used for quality checking the data for linker contamination for example.

For reads without adapters

You can decide here what to do with reads where no adapter was found. This kind of adapter trimming is particularly useful for small RNA sequencing where the remnants of the adapter is an indication that this is indeed a small RNA. Beware of lists where multiple adapters have been set to "Discard the read" when the adapters are not found: only sequences containing all the adapters will remain in the list of trimmed reads.

Alignment scores costs

An A,C,G or T in the adapter that matches an A,C,G or T respectively - or a corresponding ambiguity code letter - in a sequence is considered a match and will be awarded 1 point. However, you can decide how much penalty should be awarded to mismatches and gaps:

- **Mismatches** The penalty for mismatches between bases is set as 2 by default.
- **Gap** The penalty for gaps introduced into the alignment is set as 3 by default.

Here are the few examples of adapter matches and corresponding scores (figure 24.6). These examples are all internal matches where the alignment of the adapter falls within the read.

Match thresholds

Note that there is a difference between an **internal match** and an **end match**. An end match happens when the alignment of the adapter starts at the end of the sequence that is being trimmed. This can be 5’ or 3’ depending on the option chosen in the first dialog. Note that for 3’ trim, we internally reverse-complement the read and look for a match at the 5’ end of the reverse
CHAPTER 24. PREPARE SEQUENCING DATA

Figure 24.6: Three examples showing a sequencing read (top) and an adapter (bottom). The examples are artificial, using default setting with mismatch costs = 2 and gap cost = 3.

complemented sequence. So in case of 3' trim, if a match is found at the 5' end, it will be treated as an internal match, because it is on the end of the sequence that is not being trimmed.

If a match can be treated as either an end match or an internal match, the workbench will treat it as an end match.

This section allows you to decide whether to

- Allow internal matches
- Allow end matches
- Allow both internal and end matches

You can also change the minimum scores for both internal and end score

- Minimum internal score is set to 10 by default
- Minimum end score is set to 4 by default

End matches have usually a lower score, as adapters found at the end of reads may be incomplete.

For example, if your adapter is 8 nucleotides long, it will never be found in an internal position with the settings set as they are by default (the minimum internal score being at 10).

Figure 24.7 shows a few examples with an adapter match at the end.

In the first two examples (d and e), the adapter sequence extends beyond the end of the read. This is what typically happens when sequencing small RNAs where you sequence part of the adapter. The third example (f) shows a case that could be interpreted both as an end match and an internal match. However, the workbench will interpret this as an end match, because it starts at beginning (5' end) of the read. Thus, the definition of an end match is that the alignment of the adapter starts at the read’s 5’ end. The last example (g) could also be interpreted as an end match, but because it is a the 3’ end of the read, it counts as an internal match (this is because you would not typically expect partial adapters at the 3’ end of a read).

Below (figure 24.8), the same examples are re-iterated showing the results when applying different scoring schemes. In the first round, the settings are:
CHAPTER 24. PREPARE SEQUENCING DATA

Figure 24.7: Four examples showing a sequencing read (top) and an adapter (bottom). The examples are artificial.

- When an adapter is found: Remove adapter and the preceding sequence (5' trim)
- Allowing internal matches with a minimum score of 6
- Not allowing end matches

Figure 24.8: The results of trimming with internal matches only. Red is the part that is removed and green is the retained part. Note that the read at the bottom is completely discarded.

A different set of adapter settings could be:

- When an adapter is found: Remove adapter and the preceding sequence (5' trim)
• Allowing internal matches with a minimum score of 11
• Allowing end match with a minimum score of 4

The results of such settings is shown in figure 24.9.

Figure 24.9: The results of trimming with both internal and end matches. Red is the part that is removed and green is the retained part.

Click on the button labeled Finish to create the trim adapter list. You must now save the generated trim adapter list in the Navigation Area. You can do this by clicking on the tab and dragging and dropping the trim adapter list to the desired destination, or you can go to File in the menu bar and choose Save as.

Creating a Trim adapter list based on the Trim Reads report

Since the automatic option works conservatively with data of low quality, you can benefit from creating a new Adapter Trim List based on the report generated by running the Trim Reads tool a first time.

1. Start the Trim Reads tool.
2. Select the reads you want to analyze (or a subset of these).
3. Leave the Quality trimming settings as they are set by default.
4. In the Adapter trimming step, make sure that the option "Automatic read-through adapter trimming" is selected and that no Adapter Trim List is specified.

5. Leave the Sequence filtering settings at their default value, i.e. with no filtering.

6. In the Result handling step ensure that "Create Report" is selected and click Finish.

Once the process is completed, open the report and scroll down to the last section named "5 Automatic adapter read-through trimming" (as seen in figure 24.10).

![Figure 24.10: Use the statistics of the read-through trimming to create a Trim adapter list.](image)

- If the detected "Read-through sequence" is < 10 bp, read-through adapters are not a big issue in your data and it can be trimmed using the "Automatic read-through adapter trimming" on its own. You do not need to re-run the tool with an adapter trimming list.

- If the detected "Read-through sequence" is > or equal to 10 bp, we recommend that you re-run the Trim Reads tool with a Trim adapter list generated using the report results.

To create a Trim adapter list with the read-though sequence from the report:

1. In the report, copy the sequence of the detected "Read-through sequence". If the sequence is long, then copy only the first 19 to 24 bp.

2. Go to **New | Adapter Trim List**.

3. Click the **Add row** button.

4. Type the name of the first adapter, for example Read 1 read-through adapter.

5. Paste the copied sequence.

6. Set the Reads option to **First read**.

7. Choose the option **Remove the adapter and the following sequence (3’ trim)**.

8. For reads without adapters choose the option **Keep the Read**.
9. In the Set scoring dialog, leave the default settings and click **Finish**.

10. Repeat for the procedure with the read-through sequence for read 2.

11. Save the Trim adapter list before closing it.

You can now use this Trim adapter list in combination with the "Automatic read-through adapter trimming" option for optimal adapter trimming of all samples in your experiment.

**Importing an adapter list**

It is possible to import a trim adapter list from an Excel or CSV file, using the Standard import with either the Automatic Import option, or the Force Import as Type: Trim Adapter List option.

To import a trim adapter list, the names of all adapters must be unique - the workbench is unable to accept files with multiple rows containing the same adapter name. The file must also include the following information: Name, Sequence, Reads, When an adapter is found, For reads without adapters, Alignment score

For CSV file, the text between each comma that designates a new column should be quoted, as shown in figure 24.11:

```
"Name","Sequence","Reads","When an adapter is found","For reads without adapters","Alignment score"
"ATC 5′ trim 1st read","AGTCAGATCA","1","Keep the read","Mismatch: 0, Gapcost: 3, Cutoff: 10, Cutoff at end: 4"
"ATC 5′ trim 1st read","AGTCAGATCA","1","Keep the read","Mismatch: 0, Gapcost: 3, Cutoff: 10, Cutoff at end: 4"
"ATC 5′ trim 1st read","AGTCAGATCA","1","Keep the read","Mismatch: 0, Gapcost: 3, Cutoff: 10, Cutoff at end: 4"
```

Figure 24.11: The expected import format for Adapter Lists.
24.2.4 Length trimming

Clicking **Next** will allow you to specify length trimming as shown in figure 24.12.

![Figure 24.12: Trimming on length.](image)

At the top you can choose to **Trim bases** by specifying a number of bases to be removed from either the 3’ or the 5’ end of the reads. Below you can choose to **Discard reads below length**. This can be used if you wish to simply discard reads because they are too short. Similarly, you can discard reads above a certain length. This will typically be useful when investigating e.g. small RNAs (note that this is an integral part of the small RNA analysis together with adapter trimming).

24.2.5 Trim output

Clicking **Next** will allow you to specify the output of the trimming as shown in figure 24.13.

![Figure 24.13: Specifying the trim output.](image)

In most case, independently of what option are selected in this dialog, a list of trimmed reads will be generated:

- Sequence elements (individual sequences) selected as input and not discarded during trimming will be output into a single sequence list, as long as one or more of the input sequences were trimmed.
- Sequence lists selected as input will be output as as many corresponding sequence list, assuming that at least one sequence in any one of the sequence lists input was trimmed.
However, if no sequences are trimmed using the parameter settings provided, then no sequence lists are output when running the tool directly. A warning message appears stating that no sequences were trimmed. When the tool is run within a workflow, and if no sequences are trimmed using the parameter settings provided, then all input sequences are passed to the next step of the analysis via the "Trimmed Sequences" output channel.

In addition the following can be output as well:

- **Save discarded sequences.** This will produce a list of reads that have been discarded during trimming. Sections trimmed from reads that are not themselves discarded will not appear in this list.

- **Save broken pairs.** This will produce a list of orphan reads.

- **Create report.** An example of a trim report is shown in figure 24.14. The report includes the following:
  - **Trim summary.**
    - **Name.** The name of the sequence list used as input.
    - **Number of reads.** Number of reads in the input file.
    - **Avg. length.** Average length of the reads in the input file.
    - **Number of reads after trim.** The number of reads retained after trimming. This includes both paired and orphan reads.
    - **Percentage trimmed.** The percentage of the input reads that are retained.
    - **Avg. length after trim.** The average length of the retained sequences.
  - **Read length before / after trimming.** This is a graph showing the number of reads of various lengths. The numbers before and after are overlayed so that you can easily see how the trimming has affected the read lengths (right-click the graph to open it in a new view).
  - **Trim settings** A summary of the settings used for trimming.
  - **Detailed trim results.** A table with one row for each type of trimming:
    - **Input reads.** The number of reads used as input. Since the trimming is done sequentially, the number of retained reads from the first type of trim is also the number of input reads for the next type of trimming.
    - **No trim.** The number of reads that have been retained, unaffected by the trimming.
    - **Trimmed.** The number of reads that have been partly trimmed. This number plus the number from **No trim** is the total number of retained reads.
    - **Nothing left or discarded.** The number of reads that have been discarded either because the full read was trimmed off or because they did not pass the length trim (e.g. too short) or adapter trim (e.g. if **Discard when not found** was chosen for the adapter trimming).
  - **Automatic adapter read-through trimming.** This section contains statistics about how many reads were automatically trimmed for adapter read-through. It will also list the two detected read-through sequences.

If you trim paired data, the result will be a bit special. In the case where one part of a paired read has been trimmed off completely, you no longer have a valid paired read in your sequence list.
1 Trim summary

<table>
<thead>
<tr>
<th>Name</th>
<th>Number of reads</th>
<th>Avg. length</th>
<th>Number of reads after trim</th>
<th>Percentage trimmed</th>
<th>Avg. length after trim</th>
</tr>
</thead>
<tbody>
<tr>

<td>57,213</td>
<td>228.0</td>
<td>55,754</td>
<td>&gt;100%</td>
<td>232.8</td>
</tr>
</tbody>
</table>

2 Read length before / after trimming

Figure 24.14: A report with statistics on the trim results. Note that the Average length after trimming (232.8bp) is bigger than before trimming (228bp) because 2,000 very short reads were discarded in the trimming process.

In order to use paired information when doing assembly and mapping, the Workbench therefore creates two separate sequence lists: one for the pairs that are intact, and one for the single reads where one part of the pair has been deleted. When running assembly and mapping, simply select both of these sequence lists as input, and the Workbench will automatically recognize that one has paired reads and the other has single reads.

24.3 Demultiplex Reads

Multiplexing techniques are often used when sequencing different samples in one sequencing run. One method used is to tag the sequences with a unique identifier during the preparation of the sample for sequencing [Meyer et al., 2007].

With this technique, each sequence read will have a sample-specific tag, which is a specific sequence of nucleotides before and after the sequence of interest. This principle is shown in figure 24.15.

The sample-specific tag, also called the barcode or the index, can then be used to distinguish between the different samples when analyzing the sequencing data. Post-processing of the sequencing data is required to separate the reads into their corresponding samples. Based on their barcodes this can be done using the demultiplexing functionality of the
CHAPTER 24. PREPARE SEQUENCING DATA

Figure 24.15: Tagging the target sequence, which in this case is single reads from one sample.

CLC Genomics Workbench. Using this tool, sequences are associated with a particular sample when they contain an exact match to a particular barcode. Sequences that do not contain an exact match to any of the barcode sequences provided are classified as not grouped and are put into a sequence list with the name "Not grouped".

Note that there is also an example using Illumina data at the end of this section.

Before processing the data, you need to import it as described in section 6.3.

Please note that demultiplexing is often carried out on the sequencing machine so that the sequencing reads are already separated according to sample. This is often the best option, if it is available to you. Of course, in such cases, the data will not need to be demultiplexed again after import into the CLC Genomics Workbench.

To demultiplex your data, please go to:

**Toolbox | Prepare Sequencing Data | Demultiplex Reads**

This opens a dialog where you can specify the sequences to process (figure 24.16).

When you click on the button labeled **Next**, you can then specify the details of how the demultiplexing should be performed. At the bottom of the dialog, there are three buttons, which are used to **Add**, **Edit**, and **Delete** the elements that describe how the barcode is embedded in the sequences.

First, click **Add** to define the first element. This will bring up the dialog shown in 24.17.
At the top of the dialog, you can choose the type of element you wish to define:

- **Linker.** The linker (also known as adapter) is a sequence which should just be ignored - it is neither the barcode nor the sequence of interest. In the example in figure 24.15, the linker is two nucleotides long. For this element, you simply define its length - nothing else.

- **Barcode.** The barcode (also known as index) is the stretch of nucleotides used to group the sequences. In this dialog, you simply need to specify the length of the barcode. The valid sequences for your barcodes must be provided at a later wizard step.

- **Sequence.** This element defines the sequence of interest. You can define a length interval for how long you expect this sequence to be. The sequence part is the only part of the read that is retained in the output. Both barcodes and linkers are removed.

The concept when adding elements is that you add e.g. a linker, a barcode, and a sequence in the desired sequential order to describe the structure of each sequencing read. You can of course edit and delete elements by selecting them and clicking the buttons below. In the example shown in figure 24.15, the dialog should include a linker, a barcode, and a sequence as shown in figure 24.18.

Click on the button labeled **Next** to set the barcode options. At the top, you can choose to search on both strands for the barcodes (this is needed for some 454 protocols where the MID is located at either end of the read). In the table below, the **Preview** column will show a preview of the results by running through the first 10,000 reads (figure 24.19).
If you would like to change the name of the sequence(s), this can be done at this step by double-clicking on the specific name that you would like to change. This is shown in figure 24.20.

![Figure 24.20: The name of the sequence can be renamed by double-clicking on the existing name.](image)

In the last wizard step, where you can specify the output options. If you choose to keep the default settings, three different types of output will be generated; 1) The demultiplexed reads, one output for each specified barcode (the file name starts with "Barcode:" and is followed by the specified barcode sequence), 2) The discarded reads that did not have a barcode (this file is called "Not grouped"), and 3) a "Demultiplex Reads report", which shows the fraction of reads with and without a barcode (see figure 24.21).

![Figure 24.21: Three different outputs are generated when analyzing single reads with only one sample using the default output settings. If several samples had been mixed together there would be a sequence list for each sample (each specified barcode). The Demultiplex Reads report is shown in the right-hand side of the figure.](image)

If you have paired data the procedure is exactly the same, except for one thing: the dialog shown in figure 24.18 will be displayed twice - one for each part of the pair.

Figure 24.22 shows an example that could illustrate paired end reads. In this example we have
paired end reads from two different samples mixed together.

![Diagram of paired end reads with linkers and barcodes](image)

Figure 24.22: Paired end reads with linkers and barcodes. Two different samples are mixed together in this example.

In a situation where the paired reads are expected to be barcoded in the same way (see example below), you would set the parameters for read1 (wizard step 3) and read2 (wizard step 4) to be the same.

Read1 : --Linker--Barcode1--Sequence
Read2 : --Linker--Barcode1--Sequence

However, if read2 of the pair is not expected to be the same as read1 in the pair, it is necessary to adjust these settings accordingly. For example, it is possible that read2 does not contain any barcode sequence at all. In this case, you would simply set the sequence parameter for the mate and exclude the barcode and linker parameters. If the two reads in the read pair have different barcodes, the situation would look like this:

Read1 : --Linker--Barcode1--Sequence
Read2 : --Linker--Barcode2--Sequence

To demultiplex paired end reads the first two steps are similar to the demultiplexing of single reads. Select the paired end read sequences that should be demultiplexed (figure 24.23).

![Demultiplex Reads](image)

Figure 24.23: Specifying the paired end reads to demultiplex.

Click on the button labeled Next to define the tags and sequence for the forward reads (figure 24.24).

Barcodes can be entered manually or imported from a properly formatted CSV or Excel file:

**Manually** The barcodes can be entered manually by clicking the Add button. In the example shown in figure 24.22 the barcodes should be defined as shown in figure 24.25.

You can edit the barcodes and the names by clicking the cells in the table. The barcode name is used when naming the results.
Figure 24.24: Specifying the setup of the forward read (tags and sequence).

Figure 24.25: The barcodes for the set of paired end reads for sample 1 have already been defined and the barcodes for sample 2 is being entered in the format AAA-AAA, which corresponds to Barcode1-Barcode2 for sample 2 in the example shown in figure 24.22.

**Import from CSV or Excel** To import a file of barcodes, click on the **Import** button. The input format consists of two columns: the first contains the barcode sequence, the second contains the name of the barcode. An acceptable csv format file would contain columns of information that looks like:

"AAAAAA","Sample1"
"GGGGGG","Sample2"
"CCCCCC","Sample3"

Note that double quotes around values are always necessary regardless of whether columns are separated with a comma or a semi-colon.

Click on the button labeled **Next** to define the tags and sequence for the reverse reads and set barcode options as explained for single reads above. Then click **Next** to specify the output options. First, you can choose to create a list of the reads that could not be grouped. Second, you can create a summary report showing how many reads were found for each barcode. Click **Finish** to perform the demultiplexing.

There is also an option to create subfolders for each sequence list. This can be handy when the results need to be processed in batch mode (see section 9.3).

A new sequence list will be generated for each barcode containing all the sequences where this barcode is identified. Both the linker and barcode sequences are removed from each of
the sequences in the list, so that only the target sequence remains. This means that you can continue the analysis by doing trimming or mapping. Note that you have to perform separate mappings for each sequence list.

An example of the demultiplexing summary report is shown in figure 24.26.

![Barcodes chart]

Figure 24.26: An example of a report showing the number of reads in each group. In this example four different barcodes were used to separate four different samples.
24.3.1 An example using Illumina barcoded sequences

The data set in this example can be found at the Short Read Archive at NCBI. Use the Search for Reads in SRA... tool to search for SRX014012. Select the SRR03730 item and click **Download Reads and Metadata**. Save the sequence list in the Navigation Area, and use it with the Demultiplex Reads tool.

The barcoding was done using the following tags at the beginning of each read: CCT, AAT, GGT, CGT (see supplementary material of Cronn et al., 2008). The settings in the dialog should thus be as shown in figure 24.27.

![Figure 24.27: Setting the barcode length at three.](image)

Click next to the "Set barcode options" dialog and use the **Add** button) to specify the bar codes as shown in figure 24.28.

![Figure 24.28: A preview of the result](image)

With this data set we got the four groups as expected (shown in figure 24.29). The **Not grouped**
list contains 445,560 reads that will have to be discarded since they do not have any of the barcodes.

Figure 24.29: The result is one sequence list per barcode and a list with the remainders

25.1 Map Reads to Reference

Read mapping is a very fundamental step in most applications of high-throughput sequencing data. *CLC Genomics Workbench* includes read mapping in several other tools (such as in the Map Reads to Contigs tool, or for RNA-Seq Analysis), but this chapter will focus on the core read mapping algorithm. At the end of the chapter you can find descriptions of the read mapping reports and a tool to merge read mappings.

In addition, the mapper has special modes for handling PacBio reads and reads longer than 500bp. Before the Map Reads to Reference tool starts to map the reads, it checks the input sequence list(s) to decide on the mapping algorithm to use:

- If the input sequence list(s) have the read group set to "PacBio", then the specialized mapping algorithm which is better suited for mapping long reads with many sequencing errors is applied.
- If the input sequence list(s)’ read group is not set to "PacBio", then the reads are mapped using our standard mapping algorithm. The standard mapping algorithm uses the same seeding method for all input reads, but different extension methods for long (>500 bp) and short reads.

It is possible to mix sequence lists that have the platform field of the read group "PacBio" with sequence lists that have a different read group for the same mapping. In this case the appropriate mapping algorithm will be applied to each of the sequence lists.

25.1.1 Selecting the reads

To start the read mapping:

Toolbox | Resequencing Analysis | Map Reads to Reference

In the first dialog, select the sequences or sequence lists containing the sequencing data (figure 25.1). Please note that reads longer than 100,000 bases are not supported.

![Map Reads to Reference dialog](image)

Figure 25.1: Specifying the reads as input. You can also choose to work in batch.

25.1.2 References and masking

When the sequences are selected, click Next, and you will see the dialog shown in figure 25.2.
At the top, select one or more reference sequences by clicking the Browse button. You can select either single sequences, a list of sequences or a sequence track as reference. Note the following constraints:

- single reference sequences longer than 2gb ($2 \cdot 10^9$ bases) are not supported.
- a maximum of 120 input items (sequence lists or sequence elements) can be used as input to a single read mapping run.

**Including or excluding regions (masking)**

The next part of the dialog shown in figure 25.2 lets you mask the reference sequences. Masking refers to a mechanism where parts of the reference sequence are not considered in the mapping. This can be useful for example when mapping data is captured from specific regions (e.g. for amplicon resequencing). The output will still include the full reference sequence, but no reads will be mapped in the ignored regions.

Note that you should be careful that your data is indeed only sequenced from the target regions. If not, some of the reads that would have matched a masked-out region perfectly may be placed wrongly at another position with a less-perfect match and lead to wrong results for subsequent variant calling. For resequencing purposes, we recommend testing whether masking is appropriate by running the same data set through two rounds of read mapping and variant calling: one with masking and one without. At the end, comparing the results will reveal if any off-target sequences cause problems in the variant calling.

Masking out repeats or using other masks with many regions is not recommended. Repeats are handled well without masking and do not cause any slowdown. On the contrary, masking repeats is likely to cause a dramatic slowdown in speed, increase memory requirements and lead to incorrect read placement.

To mask a reference sequence, first click the Include or Exclude options, and then click the Browse button to select a track to use for masking. If you have annotations on a sequence instead of a track, you can convert the annotation type to a track (see section 23.5).

**25.1.3 Mapping parameters**

Clicking Next leads to the parameters for the read mapping (see figure 25.3).
Figure 25.3: Setting parameters for the mapping.

The first parameter allows the mismatch cost to be adjusted:

- **Match score** The positive score for a match between the read and the reference sequence. It is set by default to 1 but can be adjusted up to 10.

- **Mismatch cost** The cost of a mismatch between the read and the reference sequence. Ambiguous nucleotides such as "N", "R" or "Y" in read or reference sequences are treated as mismatches and any column with one of these symbols will therefore be penalized with the mismatch cost.

After setting the mismatch cost you need to choose between linear gap cost and affine gap cost, and depending on the model you choose, you need to set two different sets of parameters that control how gaps in the read mapping are penalized.

- **Linear gap cost** The cost of a gap is computed directly from the length of the gap and the insertion or deletion cost. This model often favors small, fragmented gaps over long contiguous gaps. If you choose linear gap cost, you must set the insertion cost and the deletion cost:
  
  **Insertion cost** The cost of an insertion in the read (a gap in the reference sequence). The cost of an insertion of length $\ell$ will be
  
  $$\ell \cdot \text{Insertion cost}, \quad (25.1)$$

  **Deletion cost** The cost of a deletion in the read (gap in the read sequence). The cost of a deletion of length $\ell$ will be
  
  $$\ell \cdot \text{Deletion cost}. \quad (25.2)$$

- **Affine gap cost** An extra cost associated with opening a gap is introduced such that long contiguous gaps are favored over short gaps. If you chose affine gap cost, you must also set the cost of opening an insertion or a deletion:
**Insertion open cost** The cost of opening an insertion in the read (a gap in the reference sequence).

**Insertion extend cost** The cost of extending an insertion in the read (a gap in the reference sequence) by one column.

**Deletion open cost** The cost of a opening a deletion in the read (gap in the read sequence).

**Deletion extend cost** The cost of extending a deletion in the read (gap in the read sequence) by one column.

Using affine gap cost, an insertion of length \( \ell \) is penalized by

\[
\text{Insertion open cost} + \ell \cdot \text{Insertion extend cost},
\]

and a deletion of length \( \ell \) is penalized by

\[
\text{Deletion open cost} + \ell \cdot \text{Deletion extend cost}.
\]

In this way long consecutive gaps get a lower cost per column than small fragmented gaps and they are therefore favored.

Adjusting the cost parameters above can improve the mapping quality, especially when the read error rate is high or the reference is expected to differ significantly from the sequenced organism. For example, if the reads are expected to contain many insertions and/or deletions, it can be a good idea to lower the insertion and deletion costs to allow more of such errors. However, one should also consider the possible drawbacks when adjusting these settings: reducing the insertion and deletion cost increases the risk of mapping reads to the wrong positions in the reference.

![Figure 25.4](image)

Figure 25.4: An alignment of a read where a region of 35bp at the start of the read is unaligned while the remaining 57 nucleotides matches the reference.

Figure 31.16 shows an example using linear gap cost where the read mapper is unable to map a region in a read due to insertions in the read and mismatches between the read and the reference. The aligned region of the read has a total of 57 matching nucleotides which result in an alignment score of 57 which is optimal when using the default cost for mismatches and insertions/deletions (2 and 3 respectively). If the mapper had aligned the remaining 35bp of the read as shown in figure 31.17 using the default scoring scheme, the score would become:

\[
(26 + 1 + 3 + 57) \times 1 - 5 \times 2 - 8 \times 3 = 53
\]

In this case, the alignment shown in figure 31.16 is optimal since it has the highest score. However, if either the cost of deletions or mismatches were reduced by one, the score of the alignment shown in figure 31.17 would become 61 and 58, respectively, and thus make it optimal.

Once the optimal alignment of the read is found, based on the cost parameters described above, a filtering process determines whether this match is good enough for the read to be included in the output. The filtering threshold is determined by two factors:
CHAPTER 25. READ MAPPING

Figure 25.5: An alignment of a read containing a region with several mismatches and deletions. By reducing the default cost of either mismatches or deletions the read mapper can make an alignment that spans the full length of the read.

- **Length fraction** The minimum percentage of the total alignment length that must match the reference sequence at the selected similarity fraction. A fraction of 0.5 means that at least half of the alignment must match the reference sequence before the read is included in the mapping (if the similarity fraction is set to 1). Note, that the minimal seed (word) size for read mapping is 15 bp, so reads shorter than this will not be mapped.

- **Similarity fraction** The minimum percentage identity between the aligned region of the read and the reference sequence. For example, if the identity should be at least 80% for the read to be included in the mapping, set this value to 0.8. Note that the similarity fraction relates to the length fraction, i.e. when the length fraction is set to 50% then at least 50% of the alignment must have at least 80% identity (see figure 31.18).

Figure 25.6: A read containing 59 nucleotides where the total alignment length is 60. The part of the alignment that gave rise to the optimal score has length 58 which excludes 2 bases at the left end of the read. The length fraction of the matching region in this example is therefore 58/60 = 0.97. Given a minimum length fraction of 0.5, the similarity fraction of the alignment is computed as the maximum similarity fraction of any part of the alignment which constitute at least 50% of the total alignment. In this example the marked region in the alignment with length 30 (50% of the alignment length) has a similarity fraction of 0.83 which will satisfy the default minimum similarity fraction requirement of 0.8.

- **Global alignment** By default, mapping is done with local alignment of the reads to the reference. The advantage of performing local alignment instead of global alignment is that the ends are automatically left unaligned if there are many differences from the reference at the ends. For many sequencing platforms, the quality of the bases drop along the read, and a local alignment approach is desirable. Note that the aligned region has to be greater than the length threshold set. If global alignment is preferred, it can be enabled with a checkbox as shown in figure 25.3.

25.1.4 Mapping paired reads

- **Auto-detect paired distances** At the bottom of the dialog shown in figure 25.3 you can specify how Paired reads should be handled. You can read more about how paired data is imported and handled in section 6.3.7. If the sequence list used as input contains paired
reads, this option will automatically be enabled - if it contains single reads, this option will not be applicable.

The CLC Genomics Workbench offers as the default choice to automatically calculate the distance between the pairs. If this is selected, the distance is estimated in the following way:

1. A sample of 100,000 reads is extracted randomly from the full data set and mapped against the reference using a very wide distance interval.

2. The distribution of distances between the paired reads is analyzed, and an appropriate distance interval is selected:
   - If less than 10,000 reads map, a simple calculation is used where the minimum distance is one standard deviation below the average distance, and the maximum distance is one standard deviation above the average distance.
   - If more than 10,000 reads map, a more sophisticated method is used which investigates the shape of the distribution and finds the boundaries of the peak.

3. The full sample is mapped using this distance interval.

4. The history of the result records the distance interval used.

The above procedure will be run for each sequence list used as input, assuming that they do not necessarily share the same library preparation and could have different distributions of paired distances. Figure 31.19 shows an example of the distribution of intervals with and without automatic pair distance interval estimation.

![Figure 25.7: To the left: mapping with a narrower distance interval estimated by the workbench. To the right: mapping with a large paired distance interval (note the large right tail of the distribution).](image)

Sometimes the automatic estimation of the distance between the pairs may return a warning "multiple intervals detected". This may happen if the reads derive from multiple libraries or from certain types of amplicon sequencing protocols. In this case, the estimates may still be correct, but, if in doubt, you may want to disable the option to automatically estimate paired distances and instead manually specify minimum and maximum distances between pairs on the input sequence list.

If the automatic detection of paired distances is not checked, the mapper will use the information about minimum and maximum distance recorded on the input sequence lists (see section 6.3.7).
The 'automatic detection of paired distance' option when mapping should be used with caution. It is possible that the estimated distance setting is too narrow and consequently many read pairs will be flagged broken. Sometimes, a second peak in the Paired Distance distribution graph is not picked up on by the estimation tool.

If a large portion of pairs are flagged 'Broken' we recommend the following:

1. Inspect the detailed mapping report (see section 27.1.2) to deduce a distance setting interval - and compare this to the estimated distance used by the mapper (found in the mapping history).

2. Open the paired reads list and set a broad paired distance in the Elements tab. Then run a new mapping with the 'auto-detect...' OFF. Make sure to have a report produced. Open this report and look at the Paired Distance Distribution graph. This will tell you the distances that your pairs did map with. Use this information to narrow down the distance setting and perhaps run a third mapping using this.

3. Another cause of excessive amounts of broken pairs is misspecification of the read pair orientation. This can be changed in the Elements tab of the paired reads list prior to running a mapping.

See section 27.1.2 for further information.

When a paired distance interval is set, the following approach is used for determining the placement of read pairs:

- First, all the optimal placements for the two individual reads are found.

- Then, the allowed placements according to the paired distance interval are found.

- If both reads can be placed independently but no pairs satisfies the paired criteria, the reads are treated as independent and marked as a broken pair.

- If only one pair of placements satisfy the criteria, the reads are placed accordingly and marked as uniquely placed even if either read may have multiple optimal placements.

- If several placements satisfy the paired criteria, the pair is treated as a non-specific match (see section 25.1.5 for more information.)

- If one read is uniquely mapped but the other read has several placements that are valid given the distance interval, the mapper chooses the location that is closest to the first read.

25.1.5 Non-specific matches

At the bottom of the dialog, you can specify how Non-specific matches should be treated. The concept of Non-specific matches refers to a situation where a read aligns at more than one position with an equally good score. In this case you have two options:

- Random. This will place the read in one of the positions randomly.

- Ignore. This will not include the read in the final mapping.
Note that a read is only considered non-specific when the read matches equally well at several alignment positions. For example, if there are two possible alignment positions and one of them is a perfect match and the other involves a mismatch, the read is placed at the position with the perfect match and it is not marked as a non-specific match.

For paired data, reads are only considered non-specific matches if the entire pair could be mapped elsewhere with equal scores for both reads, or if the pair is broken in which case a read can be categorized as non-specific in the same way as single reads (see section 25.1.4).

When looking at the mapping, the default color for non-specific matches is yellow.

### 25.1.6 Gap placement

In the case of insertions or deletions in homopolymeric or repetitive regions, the precise placement of the insertion or deletion cannot be determined from the data. An example is shown in figure 31.20.

![Figure 25.8: Three A’s in the reference (top) have been replaced by two A’s in the reads (shown in red). The gap is placed towards the 5’ end, but could have been placed towards the 3’ end with an equally good mapping score for the read.](image)

In this example, three A’s in the reference (top) have been replaced by two A’s in the reads (shown in red). The gap is placed towards the 5’ end (left side), but could have been placed towards the 3’ end with an equally good mapping score for the read as shown in figure 31.21.

![Figure 25.9: Three A’s in the reference (top) have been replaced by two A’s in the reads (shown in red). The gap is placed towards the 3’ end, but could have been placed towards the 5’ end with an equally good mapping score for the read.](image)

Since either way of placing the gap is arbitrary, the goal of the mapper is to place the gaps consistently at the same side for all reads.

Many insertions and deletions in homopolymeric or repetitive regions reported in the public databases dbSNP and 1000 Genomes have been identified based on mappings done with tools like BWA and Bowtie, that place insertions or deletions at the left side of a homopolymeric tract. Thus, to help facilitate the comparison of variant results with such public resources, the Map
Reads to Reference tool will place insertions or deletions in homopolymeric tracts at the left hand side.

This is a change to earlier versions of the CLC Genomics Workbench (version 6.0.5 and earlier) where the read mapper placed insertions and deletions in homopolymeric tracts at the right hand side of the homopolymer, as viewed in the Workbench.

For users of the COSMIC database or other clinical databases following the recommendations from the Human Genome Variation Society (HGVS) The Human Genome Variation Society (HGVS) recommendations, which pertain to variants within genes, state that for insertions and deletions in homopolymeric or repetitive regions, the most 3’ position (corresponding to the strand of the gene) possible should be arbitrarily assigned as the site of change (see http://varnomen.hgvs.org/). Resources such as COSMIC adhere to these recommendations. In this case, placement to the farthest possible left hand position, as viewed in the CLC Genomics Workbench, of insertions or deletions in repetitive or homopolymeric tracts, has a different effect, depending on whether the gene involved is on the positive or negative strand of the reference. Such variants located within genes on the negative strand can be compared with the COSMIC database, while those within genes lying on the positive strand cannot be, as the positions relative to the reference will be different in this case.

25.1.7 Mapping computational requirements

The memory requirements of Map Reads to Reference depends on four factors: the size of the reference, the length of the reads, the read error rate and the number of CPU cores available. The limiting factor is often the size of the reference, while the contribution of the other three factors to the total memory consumption is usually small (see below).

A good estimate for the memory required by the base space read mapper to represent a reference is one MB for each Mbp in the reference. For example the human reference genome requires $3200 \times 1\text{MB} = 3.2\text{GB}$ of memory.

An additional 4GB of memory should be reserved for the CLC Genomics Workbench, and thus the recommended minimum amount of memory for mapping short high quality reads (e.g. Illumina reads) to the human genome is 8GB. However, when mapping long reads with a high error rate, such as PacBio reads, each CPU core can add several hundred MB to the total memory consumption. Consequently, mapping long reads with high error rate on a machine with many CPU cores, can cause a large increase in the memory requirements for all CLC read mappers.

25.1.8 Reference caching

In some cases, repeated mappings against the same reference will result in a dramatically reduced runtime because the internal data structure used for mapping the reads, which is reference specific, can be reused. This has been enabled by storing files in the system tmp folder as a caching mechanism. Only a certain amount of disk space will be used and once reaching the limit, the oldest files are cleaned up. Consequently, the reference data structure files will automatically have to be recreated if the cache was filled or the tmp folder was cleaned up.

The default space limit is 8 GB but can be changed by going to Edit | Preferences | Advanced | Read Mapper
25.1.9 Mapping output options

Click Next lets you choose how the output of the mapping should be reported (see figure 25.10).

Figure 25.10: Mapping output options.

The main choice in output format is at the top of the dialog - the read mapping can either be stored as a track or as a stand-alone read mapping. Both options have distinct features and advantages:

**Reads track** A reads track is best used in the context of a Track List, where additional information about the reference, consensus sequence or annotations can be added and viewed alongside the reads. Details about viewing and editing Reads tracks are described in section 23. Unless any specific functionality of the stand-alone read mapping is required, we recommend to using the tracks output for the additional flexibility it brings in further analysis.

**Stand-alone read mapping** This output is more elaborate than the reads track and includes the full reference sequence with annotations. A consensus sequence is created as part of the output. Furthermore, the possibilities for detailed visualization and editing are richer than for the reads track (see section 18.7). However, stand-alone read mappings do not lend themselves well to comparative analyses. Note that if multiple reference sequences are used as input, a read mapping table is created (see section 25.2.3).

Read more about both output types in section 25.2. Note that the choice you make here is not definitive: it is possible to convert stand-alone read mappings to tracks and tracks (reads and annotation tracks) to stand-alone read mappings (see section 23.5).

In addition to the choice between the two main output options, there are two independent output options available that can be (de-)activated in both cases:

- **Create report.** This will generate a summary report as described in section 25.1.10.
- **Collect un-mapped reads.** This will collect all the reads that could not be mapped to the reference into a sequence list (there will be one list of unmapped reads per sample, and
for paired reads, there will be one list for intact pairs and one for single reads where the mate could be mapped).

Finally, you can choose to save or open the results. Clicking Finish will start the mapping.

25.1.10 Summary mapping report

If you choose to create a report as part of the read mapping (see section 25.2), this report will summarize the results of the mapping process. An example of a report is shown in figure 25.11

1 Mapping summary report

</tbody>
</table>

1.2 Distribution of read length

The information included in the report is:

- **Summary statistics.** A summary of the mapping statistics:
  - Reads. The number of reads and the average length.
  - Mapped. The number of reads that are mapped and their average length.
  - Not mapped. The number of reads that do not map and their average length.
  - References. Number of reference sequences.
- **Parameters.** The settings used are reported for the process as a whole and for each sequence list used as input.

- **Distribution of read length.** For each sequence length, you can see the number of reads and the distribution in percent. This is mainly useful if you don’t have too much variance in the lengths as in e.g. Sanger sequencing data.

- **Distribution of matched reads lengths.** Equivalent to the above, except that this includes only the reads that have been matched to a contig.

- **Distribution of non-matched reads lengths.** Show the distribution of lengths of the rest of the sequences.

You can copy the information from the report by selecting in the report and click Copy. You can also export the report in Excel format.

### 25.2 Reads tracks and stand-alone read mappings

This section describes the common features and differences that exist between the two types of output that are generated by the Map Reads to Reference tool.

As a reminder, here are the main differences between tracks and mappings.

**Reads track**

- seamlessly integrates with subsequent analyses
- best viewed in a Track List for comparison with other tracks
- an overflow graph above the reads in the reads track shows reads that cannot be displayed in the track

**Stand-alone read mapping**

- rich visualization and editing features (see section 18.7)
- includes a consensus sequence and a coverage graph

Remember that it is possible to convert to and from tracks (see section 23.5).

#### 25.2.1 Coloring of mapped reads

The mapped reads are colored by default according to the following color code (see figure 25.12 for a simplified illustration of the color scheme):

- Single reads mapping in their forward direction are green.
- Single reads mapping in their reverse direction are red.
- Paired reads are blue. Reverse paired reads are light blue (always in stand-alone read mapping, and only if the option "Highlight reverse paired reads" is checked, as it is by default, in reads tracks). The thick line represents the read itself; the thin line represents the distance between each read in the pair.
Reads from **broken pairs** are colored as single reads, i.e., according to their forward/reverse orientation or as a non-specific match. In stand-alone read mappings, reads that are members of a broken pair are highlighted in **darker shades of the read color**, unless the Read layout is set to "Packed". Broken pairs and Single reads cannot be differentiated in tracks.

**Non-specific matches** are **yellow**. When a read would have matched equally well another place in the mapping, it is considered a non-specific match. This color will "overrule" the other colors. Note that when mapping to several reference sequences, i.e. chromosomes, a read is considered a double match when it matches more than once across all the chromosomes.

**Unaligned ends**, that is the part of the reads that is not mapped to the reference (also known as soft-clipped read ends) will be shown with a **faded color**, e.g., light green, light red, light blue or light yellow, depending on the color of the read.

**Deletions** are shown as **dashed lines** (figure 25.13). **Insertions** with a frequency lower than 1% are shown with a **black vertical line**.

**Mismatches** between the read and reference are shown as narrow vertical lines on the reads (or black letters on a colored background at the nucleotide level) following the Rasmol color scheme: A in red, T in green, C in blue, G in yellow (figure 25.14). Ambiguous bases are in gray.
Figure 25.14: Mismatches between the reads and reference are shown as narrow vertical traits following the Rasmol color scheme. A reads track is shown above, a read mapping below.

These default colors can be changed using the side panel as shown in figure 25.15.

If your read mapping or track shows the message 'Too much data for rendering' on a gray background, simply zoom in to see your reads in more detail. This occurs when there are too many reads to be displayed clearly. More specifically, where there are more than 500,000 reads displayed in a reads track, more than 200,000 reads displayed in a read mapping, or when the region being viewed in a read mapping is longer than 200,000 bases. Paired reads count as one in these cases.

25.2.2 Reads tracks

The main advantage of having the output of the read mapping process represented as a track is that this way it seamlessly integrates with other downstream analysis tools. So unless any specific functionality of the stand-alone read mapping is required, we recommend to use the tracks output for the additional flexibility in further analysis. Later it is possible to convert to and from tracks (see section 23.5).

When the option "Create reads track" is chosen when running the tool "Map Reads to Reference", only the reads themselves will be saved. It is always possible to add information about the reference, consensus sequence or annotations later by creating a Track List.

A reads track will display two types of different information depending on the zooming level at which it is set.

When zoomed out to the point where the amount of data in the view reaches the data aggregation setting, the track shows aggregated mapped reads (figure 25.16), so the height of the graph reflect the coverage of a particular region on the mapping. In addition, three blue shades differentiate from top to bottom:
The data aggregation view is an alternative way of displaying a large amount of data (mapped reads) on the screen in order to shorten the data display time. This aggregated view allows you to navigate the view more smoothly.

In figure 25.17 we have zoomed in on a reads track displayed in a Track List together with targeted regions and variants annotations shown below.

If you zoom in further the alignment of the reads and the reference sequence can be viewed at single nucleotide level (see figure 25.18).

In this case only a certain amount of reads are visible. In order to see more reads, increase the height of the reads track by dragging down the lower part of the track with the mouse. Also, a vertical scroll bar will appear to the right of the reads when hovering on them to navigate through high coverage regions.

Read mappings to circular genomes, and that map across the starting point of the sequence are shown both at the start and end of the reference sequence. Such reads are marked with >> at
Figure 25.16: In the aggregated Reads Track, the three blue shades represent minimum, average and maximum coverage values for the aggregated mapped reads, here a 1kb region as stated in the tooltip.

Figure 25.17: Zooming in on the tracks reveals details.

the end of the read to indicate that the alignment continues at the other end of the reference sequence.

Note that it is possible to select a portion of a read and access a right-click menu where you can choose in the Selected Read menu the following options: Copy, BLAST or Open in a New View the selected portion of the read (figure 25.19).

Reads tracks Side Panel settings

The options for the Side Panel vary depending on which track is shown in the View Area. In figure 25.21 an example is shown for a read mapping:
CHAPTER 25. READ MAPPING 601

Figure 25.18: Zoom in to see the bases of the reads and the reference sequence.

Figure 25.19: Adjusting the height of the track.

Navigation.  
• The first field gives information about which chromosome is currently shown. The drop-down list can be used to jump to a different chromosome.
• Location indicates the start and end positions of the shown region of the chromosome, but can also be used to navigate the track: enter a range or a single location point to get the visualization to zoom in the region of interest. It is also possible to enter the name of a chromosome (MT: or 5:), the name of a gene or transcript (BRCA2 or DHFR-001), or even the range on a particular gene or transcript (BRCA2:122-124)
• The Overview drop-down menu defines what is shown above the track: cytobands, or cytobands with aggregated data (figure 25.20). It can also be hidden all together.

Insertions.  Only relevant for variant tracks.

Find.  Not relevant for reads tracks, as it can only be used to search for annotations in tracks. To search for a sequence, use the Find function in the Side Panel of a stand-alone read mapping.

Track layout.  The options for the Track layout varies depending on which track type is shown. The options for a reads track are:
CHAPTER 25. READ MAPPING

Figure 25.20: Cytobands with aggregated date allows you to navigate easily where needed based on the data location.

- **Data aggregation.** Allows you to specify whether the information in the track should be shown in detail or whether you wish to aggregate data. By aggregating data you decrease the detail level but increase the speed of the data display process, which is of particular interest when working with big data sets. The threshold (in bp) for when data should be aggregated can be specified with the drop-down box. The threshold describes the unit (or "bucket") size in base pairs, above which the data will start being aggregated. The bucket size depends on the track length and the zoom level. Hence, a data aggregation threshold with a low value will only show details when zoomed in, whereas a high value means that you can see details even when zoomed out. Please note that when using the high values, it will take longer time to display the data on the screen. Figure 25.21 shows the options for a reads track and an annotation track. The data aggregation settings can be adjusted for each displayed track type.

- **Aggregate graph color.** Makes it possible to change the graph color.

- **Fix maximum of coverage graph.** Specifies the maximum coverage to be shown on the y-axis and makes the coverage on individual reads tracks directly comparable with each other. Applies across all of the read mapping tracks.

- **Only show coverage graph.** When enabled, only the coverage graph is shown and no reads are shown.

- **Stack coverage types.** Shows read specific coverage graph in layers as opposed as on top of each other.

- **Float variant reads to top.** When checked, reads with variations will appear at the top of the view.

- **Disconnect paired reads.** Disconnects paired end reads (see section 25.2.2).

- **Highlight reverse paired reads.** When enabled, read pairs with reverse orientation are highlighted with a light blue color.

- **Show quality scores.** Shows the quality score. Ticking this option makes it possible to adjust the colors of the residues based on their quality scores. A quality score of 20 is used as default and will show all residues with a quality score of 20 or below in a blue color. Residues with quality scores above 20 will have colors that correspond to the selected color code. In this case residues with high quality scores will be shown in reddish colors. Clicking once on the color bar makes it possible to adjust the colors. Double clicking on the slider makes it possible to adjust the quality score limits. In cases where no quality scores are available, blue (the color normally used for residues with a low quality score) is used as default color for such residues.

- **Hide insertions below (%).** Hides insertions where the percentage of reads containing insertions is below this value. To hide all insertions, set this value to 101.
- **Highlight variants.** Variants are highlighted
- **Matching residues as dots.** Replaces matching residues with dots, only variants are shown in letters.
- **Reads track legend.** Shows the coloring of the mapped reads, and makes it possible to change the coloring of selected reads types.

![Figure 25.21: The Side Panel for reads tracks.](image)

**Overlapping paired reads**

Depending on the sequencing protocol paired reads may overlap. If the mates of an overlapping pair disagree on one or more positions (e.g. due to sequencing errors) the viewer will represent this as a paired read with either NNN’s (gap) or a IUPAC code inserted. This reflects the way the Workbench variant detection tools would treat disagreements - if two overlapping reads do not agree about the variant base, they are both ignored. If you wish to inspect the mates of overlapping pairs you can check the side panel option ‘Disconnect paired reads’. An example is shown in figure 25.22.
Figure 25.22: Overlapping paired reads containing discrepancies in the overlapping region. The divergent area in the overlapping read pair is marked with N's and IUPAC codes in the top part of the figure. Disconnecting the paired reads by ticking the box "Disconnect Paired Reads" in the Side Panel allows you to see the individual reads.
25.2.3 Stand-alone read mapping

Reads can be mapped to linear and circular chromosomes. Read mappings to circular genomes are visualized linearly as shown in figure 25.23.

Figure 25.23: Mapping reads to a circular chromosome. Reads that are marked with double arrows at the ends are reads that map across the starting point of the sequence. The arrows indicate that the alignment continues at the other end of the reference sequence.

Reads that map across the starting point of the sequence are shown both at the start and end of the reference sequence. Such reads are marked with >> at the end of the read to indicate that the alignment continues at the other end of the reference sequence.

Note that it is possible to select a portion of a read and access a right-click menu where you can Copy or Open in a New View the selected portion of the read: these option are available for the reference sequence at all compactness levels, and for individual reads at Low and Not compact levels.

If your read mapping or track shows the message ‘Too much data for rendering’ on a grey background, simply zoom in to see your reads in more detail. This occurs when there are too many reads to be displayed clearly. More specifically, where there are more than 500,000 reads displayed in a reads track, more than 200,000 reads displayed in a read mapping, or when the region being viewed in a read mapping is longer than 200,000 bases. Paired reads count as one in these cases.

Read mapping settings

When you open a read mapping, there are many viewing options available in the Side Panel for customizing the layout.

Read layout. This section appears at the top of the Side Panel when viewing a stand-alone read mapping:

- Compactness. The compactness setting options let you control the level of detail to be displayed. This setting affects many of the other settings in the Side Panel as well as the general behavior of the view. For example: if the compactness is set to Compact, you will not be able to see quality scores or annotations on the reads, even if these are turned on via the "Nucleotide info" palette of the Side Panel. You can change the Compactness setting in the Side Panel directly, or you can use the shortcut: press and hold the Alt key while you scroll with the mouse wheel or touchpad.
– **Not compact.** This allows the mapping to be viewed in full detail, including quality scores and trace data for the reads, where this is relevant. To view such information, additional viewing options under the **Nucleotide info** view settings must also be selected. For further details on these, please see section 18.1.1 and section 11.1.

– **Low.** Hides trace data, quality scores and puts the reads’ annotations on the sequence. You can see on figure 25.24 the Edit function that are available when right-clicking on a nucleotide.

![Figure 25.24: An example of the low compactness setting.](image)

– **Medium.** The labels of the reads and their annotations are hidden, and the residues of the reads cannot be seen.

– **Compact.** Even less space between the reads.

– **Packed.** All the other compactness settings will stack the reads on top of each other, but the packed setting will use all space available for displaying the reads. When zoomed in to 100%, you can see the residues but when zoomed out the reads will be represented as lines just as with the Compact setting. The packed mode is very useful when viewing large amounts of data. However certain functionality possible with other views are not available in packed view. For example, no editing of the read mapping or selections of it can be done and color coding changes are not possible. An example of the packed setting is shown in figure 25.25.

– **Gather sequences at top.** If selected, the contributing sequence reads will automatically be placed right below the reference. This setting is not relevant when the compactness is packed.

– **Show sequence ends.** Regions that have been trimmed are shown with faded traces and residues. This illustrates that these regions have been ignored during the assembly.

– **Show mismatches.** When the compactness is packed, you can highlight mismatches which will get a color according to the Rasmol color scheme. A mismatch is whenever the base is different from the reference sequence at this position. This setting also causes the reads that have mismatches to be floated at the top of the view.

– **Disconnect paired reads.** This option will break up the paired reads in the display (they are still marked as pairs - this just affects the visualization). The reads are
Figure 25.25: An example of the packed compactness setting. We highlighted in black an example of 3 narrow vertical lines representing mismatching residues.

- **Packed read height.** When the compactness is set to "packed", you can choose the height of the visible reads. When there are more reads than the height specified, an overflow graph will be displayed below the reads. The overflow graph is shown in the same colors as the sequences, and mismatches in reads are shown as narrow vertical lines (see figure 25.25). The colors of the small lines represent the mismatching residue. The color codes for the horizontal lines correspond to the color used for highlighting mismatches in the sequences (red = A, blue = C, yellow = G, and green = T), meaning that a red line with half the height of the blue part of the overflow graph will represent a mismatching “A” in half of the paired reads at this particular position.

- **Find Conflict.** Clicking this button selects the next position where there is an conflict between the sequence reads. Residues that are different from the reference are colored (as default), providing an overview of the conflicts. Since the next conflict is automatically selected it is easy to make changes. You can also use the Space key to find the next conflict.

- **Low coverage threshold.** All regions with coverage up to and including this value are considered low coverage. When clicking the 'Find low coverage' button the next region in the read mapping with low coverage will be selected.

**Sequence layout.** There is one additional parameter to those described in section 11.1.1

- **Matching residues as dots.** Matching residues will be presented as dots. Only the top sequence will be preserved in its original format.

**Residue coloring.** There is one additional parameter to those described in section 11.1.1

- **Sequence colors.** This option lets you use different colors for the reads.
  - **Main.** The color of the consensus and reference sequence. Black per default.
  - **Forward.** The color of forward reads (single reads). Green per default.
Reverse. The color of reverse reads (single reads). Red per default.

Paired. The color of paired reads. Blue per default. Note that reads from broken pairs are colored according to their Forward/Reverse orientation or as a Non-specific match, but with a darker nuance than ordinary single reads.

Non-specific matches. When a read would have matched equally well another place in the mapping, it is considered a non-specific match. This color will "overrule" the other colors. Note that if you are mapping with several reference sequences, a read is considered a double match when it matches more than once across all the contigs/references. A non-specific match is yellow per default.

Alignment info. There are additional parameters to the ones described in section 20.2.

- **Coverage**: Shows how many sequence reads that are contributing information to a given position in the read mapping. The level of coverage is relative to the overall number of sequence reads.
- **Paired distance**: Plots the distance between the pairs of paired reads.
- **Single paired reads**: Plots the percentage of reads marked as single paired reads (when only one of the reads in a pair matches).
- **Non-specific matches**: Plots the percentage of reads that also match other places.
- **Non-perfect matches**: Plots the percentage of reads that do not match perfectly.
- **Spliced matches**: Plots the percentage of reads that are spliced.

Options for these parameters are as follow:

- **Foreground color**: Colors the letters using a gradient, where the left side color is used for low coverage and the right side is used for maximum coverage.
- **Background color**: Colors the background of the letters using a gradient, where the left side color is used for low coverage and the right side is used for maximum coverage.
- **Graph**: The coverage is displayed as a graph (Learn how to export the data behind the graph in section 6.8).
  - **Height**: Specifies the height of the graph.
  - **Type**: The graph can be displayed as Line plot, Bar plot or as a Color bar.
  - **Color box**: For Line and Bar plots, the color of the plot can be set by clicking the color box. If a Color bar is chosen, the color box is replaced by a gradient color box as described under Foreground color.

Mapping table

When several reference sequences are used or you are performing de novo assembly with the reads mapped back to the contig sequences, all your mapping data will be accessible from a table. It means that all the individual mappings are treated as one single file to be saved in the Navigation Area as a table.

An example of a mapping table for a de novo assembly is shown in figure 25.26.

The information included in the table is:

- **Name**: When mapping reads to a reference, this will be the name of the reference sequence.
CHAPTER 25. READ MAPPING

Figure 25.26: The mapping table.

- **Consensus length.** The length of the consensus sequence. Subtracting this from the length of the reference will indicate how much of the reference that has not been covered by reads.

- **Total read count.** The number of reads. Reads with multiple hits on different reference sequences are placed according to your input for **Non-specific matches**

- **Single reads** and **Reads in pair.** Total number of reads, single and/or in pair.

- **Average coverage.** This is simply summing up the bases of the aligned part of all the reads divided by the length of the reference sequence.

- **Reference sequence.** The name of the reference sequence.

- **Reference length.** The length of the reference sequence.

- **Reference common name** and **Reference latin name.** Name, common name and Latin name of each reference sequence.

At the bottom of the table there are three buttons that can be used to open or extract sequences. Select the relevant rows before clicking on the buttons:

- **Open Mapping.** Opens the read mapping for visual inspection. You can also open one mapping simply by double-clicking in the table.

- **Extract Consensus/Contigs.** For de novo assembly results, the contig sequences will be extracted. For results when mapping against a reference, the **Extract Consensus** tool will be used (see section 25.6).

- **Extract Subset.** Creates a new mapping table with the mappings that you have selected.

You can export the table in Excel format.

**Find broken pair mates**

The **Find Broken Pair Mates** tool is not applicable to tracks, but is available only to stand-alone read mappings.
Figure 25.27 shows an example of a read mapping with paired reads (shown in blue). In this particular region, there are some broken pairs (red and green reads). Pairs are marked as broken if the respective orientation or distance between the reads is not right (see general info on handling paired data in section 6.3.7), or if one of the reads do not map at all.

In some situations it is useful to investigate where the mate of the broken pairs map. This would indicate genomic rearrangements, mis-assemblies of de novo assembly etc. In order to see this, select the region in question on the reference sequence, right-click and choose Find Broken Pair Mates.

This will open the dialog shown in figure 25.28.

The purpose of this dialog is to let you specify if you want to annotate the resulting broken pair overview with annotation information. In this case, you would see if there are any overlapping genes at the position of the mates.

In addition, the dialog provides an overview of the broken pairs that are contained in the selection.
Click **Next** and **Finish**, and you will see an overview table as shown in figure 25.29.

![Figure 25.29: An overview of the broken pairs.](image)

The table includes the following information for both parts of the pair:

- **Reference**  The name of the reference sequence where it is mapped
- **Start and end**  The position on the reference sequence where the read is aligned
- **Match count**  The number of possible matches for the read. This value is always 1, unless the read is a non-specific match (marked in yellow)
- **Annotations**  Shows a list of the overlapping annotations, based on the annotation type selected in figure 25.28.

You can select some or all of these broken pairs and extract them as a sequence list for further analysis by clicking the **Create New Sequence List** button at the bottom of the view.

### 25.3 Local Realignment

The goal of the local realignment tool is to improve on the alignments of the reads in an existing read mapping. The local realignment algorithm works by exploiting the information available in the alignments of other reads when it is attempting to re-align any given read. Most mappers do not use cross-read information as it would be computationally prohibitive to do within the mapping algorithm. However, once the reads have been mapped, local realignment procedures can exploit this information.

Realignment will typically occur in areas around insertions and deletions in the sample reads relative to the reference. In such regions we wish to see our reads mapped with one end of the read on one side of the indel and the rest mapped on the other side. However, the mapper that originally mapped the reads to the reference does not have information about the existence of an indel to use when mapping a given read. Thus, reads that are mapped to such regions, but that only have a short part of the read representing the region on one side of the indel, will typically not be mapped properly across the indel, but instead be mapped with this end unaligned, or into the indel region with many mismatches. The Local Realignment tool can use information from the other reads mapping to a region containing an indel, including reads that are located more centered across the indel and thus have been mapped with ends on either side of the indel. As a result an alternative mapping, as good as or better than the original, can be generated.

Local realignment will typically have an effect on any read mapping, whether the reads were mapped using a local or global alignment algorithm (i.e. with the Global alignment option of the
mapping tool unchecked (the default) or checked, respectively. An example of the effect of using the Local Realignment tool on a read mapping made using the local alignment algorithm is shown in figure 25.30. An example in the case of a mapping made using the global alignment algorithm is shown in figure 25.31.

Figure 25.30: Local realignment of a read mapping produced with the 'local' option. [A] The alignments of the first, second, and fifth read in this read mapping do not support the four-nucleotide insertion supported by the remaining reads. A variant detection tool might be tempted to call a heterozygous insertion of four nucleotides in one allele and heterozygous replacement of four nucleotides in a second allele. [B] After applying local realignment, the first, second, and fifth read consistently support the four-nucleotide insertion.

25.3.1 Method

The local realignment algorithm uses a variant of the approach described by Homer et al. [Homer N, 2010]. In the first step, alignment information of all input reads are collected in an efficient graph-based data structure, which is essentially similar to a de-Brujn graph. This realignment graph represents how reads are aligned to the reference sequence and how reads overlap each other. In the second step, metadata are derived from the graph structure that indicate at which alignment positions realignment could potentially improve the read mapping, and also provides hypotheses as to how reads should be realigned to yield the most concise multiple alignment. In the third step the realignment graph and its metadata are used to actually perform the local realignment of each individual read. Figure 25.32 depicts a partial realignment graph for the read mapping shown in figure 25.30.
CHAPTER 25. READ MAPPING

25.3.2 Realignment of unaligned ends

A typical error in read alignments is the occurrence of unaligned ends (also known as soft-clipped read ends). These unaligned ends are introduced by the read mapper as a consequence of an unresolved indel towards the end of a read. Those unaligned ends can be realigned in many cases, after the read itself has been locally realigned according to the indel that prevented the read mapper from aligning the read ends correctly. Figure 25.33 depicts such an example.

25.3.3 Guided realignment

One limitation of the local realignment algorithm employed is that at least one read must be aligned correctly according to the true indel present in the data. If none of the reads is aligned correctly, local realignment cannot improve the alignment, since it lacks information about how to do so. To overcome this limitation, local realignment can be guided in two ways:

1. **Guidance variants:** By supplying the Local realignment tool with a track of guidance variants. There are two modes for using the guidance variant track: either the ‘un-forced’ guidance mode (if the ‘Force realignment to guidance-variants’ is left un-ticked) or the ‘forced’ guidance mode (if the ‘Force realignment to guidance-variants’ is ticked). In the
'unforced' mode, 'pseudo-reads' are given to the local realignment algorithm representing the guidance variants, allowing the local realignment algorithm to explore the paths in the graph corresponding to these alignments. In the 'forced' mode, 'pseudo-references' are given to the local realignment algorithm representing the guidance variants, allowing the reads to be aligned to allele sequences of these in addition to the original reference sequence - with matches being awarded and encouraged equally much. The 'unforced' mode can be used with any guidance variant track as input. The 'force' mode should only be used with guidance variants for which there is strong prior evidence that they exist in the data (e.g., the 'InDel' track from the Structural Variants’ tool (see Section 26.12) produced on the read mapping that is being aligned). Unless you do have strong evidence for the presence of these guidance variants, we do not recommend using the 'forced' mode as it can lead to the introduction of false positives in your alignment and all subsequent analyses.

2. **Concurrent local realignment of multiple samples**: Multiple input read mappings increase the chance to encounter at least one read mapped correctly. This guiding mechanism has been particularly designed for scenarios, where samples are known to be related, such as in family trials.
CHAPTER 25. READ MAPPING

Figure 25.34 and figure 25.35 show examples that can be improved by guiding the local realignment algorithm.

Figure 25.34: [A] Three reads are misaligned in the presence of a four nucleotide insertion relative to the reference. [B] When applying local realignment without guidance the alignment is not improved. [C] Here local realignment is performed in the presence of the guiding variant track seen in (E). This enables the algorithm to consider alternative alignments, which are accepted whenever they have significant improvements over the original (as in read three that has a comparatively long unaligned-end). [D] If the alignment is performed with the option "Force realignment to guidance-variants" enabled, the realignment will be forced to realign according to the guiding variants track shown in (E), and this will result in realignment of all three reads. [E] The guiding variants track contains, amongst others, the four nucleotide insertion.

25.3.4 Multi-pass local realignment

As described in section 25.3.1 the algorithm initially builds the realignment graph using the input read mapping. After the graph has been built the algorithm realigns individual reads based on information inferred from the realignment graph structure and its associated metadata. In some cases repetitive realignment iterations yield even more improvements, because with each realignment iteration the structure of the realignment graph changes slightly, potentially permitting further improvements. Local realignment therefore supports to perform multiple iterations implicitly. This is not only considered a convenience feature, but also saves a great deal of runtime by avoiding repeated transfers of large input data sets. For most samples local realignment will quickly saturate in the number of improvements. Generally, two realignment passes are strongly recommended. More than three passes rarely yield further improvements.

25.3.5 Known limitations

The major limitation of the local realignment algorithm is the necessity of at least one read being mapped correctly according to an indel present in the data. Insufficient alignment data results in suboptimal realignments or no realignments at all. As a work-around, local realignment can be guided by supplying a track of variants that enable the algorithm to determine improvements. Further guidance can be achieved by increasing the amount of alignment information and thereby increasing the chance to observe at least one read mapped correctly.
CHAPTER 25. READ MAPPING

25.3.6 Computational requirements

The realignment graph is produced using a sliding-window approach with a window size of 250,000 bp. If local realignment is run with multiple passes, then each pass has its own realignment graph. While memory consumption is typically below two gigabytes for single-pass, processor loads are substantial. Realigning a human sample of approximately 50x coverage will take around 24 hours on a typical desktop machine with four physical cores. Building the realignment graph and realignment of reads are parallelized actions, such that the algorithm scales very well with the number of physical cores. Server machines exploiting 12 or more physical cores typically run three times faster than the desktop with only four cores.

Figure 25.35: [B] Three reads are misaligned in the presence of a four nucleotide insertion into the reference. Applying local realignment without guiding information would not yield any improvements (not shown). [C] Performing local realignment on both samples (A) and (B) enables the algorithm to improve the alignments of sample (B).

Reads are ignored, but retained in outputs, if:

- Lengths are longer than 50,000 base pairs.
- The alignment is longer than 50,000 base pairs.
- Crossing the boundaries of circular chromosomes.

Guiding variants are ignored, if:

- They are of type "Replacement".
- They are longer than 200 bp (set as default value, but can be changed using the Maximum Guidance Variant Length parameter).
- If they are inter-chromosomal structural variations.
- If they contain ambiguous nucleotides.
25.3.7 Run the Local Realignment tool

The tool is found in the Toolbox:

Toolbox | Resequencing Analysis | Local Realignment

Select one or multiple read mappings as input. If one read mapping is selected, local realignment will attempt to realign all contained reads, if appropriate. If multiple read mappings are selected, their reference genome must exactly match. Local realignment will realign all reads from all input read mappings as if they came from the same input. However, local realignment will create one output read mapping for each input read mapping, thereby preserving the affiliation of each read to its sample. Clicking Next allows you to set parameters as displayed in figure 25.36.

Alignment settings

- **Realign unaligned ends** This option, if enabled, will trigger the realignment algorithm to attempt to realign unaligned ends as described in section "Realignment of unaligned ends (soft clipped reads)". This option should be enabled by default unless unaligned ends arise from known artifacts (such as adapter remainders in amplicon sequencing setups) and are thus not expected to be realignable anyway. Ignoring unaligned ends will yield a significant run time improvement in those cases. Realigning unaligned ends under normal conditions (where unaligned ends are expected to be realignable), however, does not contribute a lot of processing time.

- **Multi-pass realignment** This option is used to specify how many realignment passes should be performed by the algorithm. More passes improve accuracy at the cost of longer run time (approx. 25% per pass). Two passes are recommended; more than three passes barely yield further improvements.

Guidance-variant settings

- **Guidance-variant track** A track of variants to guide realignment of reads. Guiding can be used in at least two scenarios: (1) if reads are short or expected variants are long and (2) if cross sample comparisons are performed and some samples are already well genotyped. A track of variants can be produced by any of the variant detection tool, the Indels and Structural Variants tool or by importing variants from external data sources, such as dbSNP, etc.
Maximum Guidance Variant Length set at 200 by default but can be increased to include guidance variants longer than 200 bp.

There are two modes for using the guidance track:

- **Un-forced** If the 'Force realignment to guidance-variants' is un-ticked the guidance variants are used as 'weak' prior evidence: each guidance variant will be represented by a pseudo-read, allowing the local realignment to explore the alignments that the guidance variants suggest. Any variant track may be used to guide the realignment when the un-forced mode is chosen.

- **Force realignment to guidance-variants** If the 'Force realignment to guidance-variants' is ticked the guidance variants are used as 'strong' prior evidence: a 'pseudo' reference will be generated for each guidance variant, and the alignment of nucleotides to their sequences will be awarded and encouraged as much as the alignment to the original reference sequence. Thus, the 'Force realignment to guidance-variants' options should only be used when there is prior information that the variants in the guidance variant track are in fact present in the sample. This would e.g. be the case for an 'InDel' track produced by the Structural Variant tool (see Section 26.12), in an analysis of the same sample as the realignment is carried out on. Using 'forced' realignment to a general variant data base track is generally strongly discouraged.

The next dialog allows specification of the result handling. Under "Output options" it is possible to specify whether the results should be presented as a reads track or a stand-alone read mapping (figure 25.37).

Figure 25.37: An output track of realigned regions can be created.

If enabled, the option **Output track of realigned regions** will cause the algorithm to output a track of regions that help pinpoint regions that have been improved by local realignment. This track has purely informative intention and cannot be used for anything else.

### 25.4 Merge Read Mappings

If you have performed two mappings with the same reference sequences, you can merge the results using the **Merge Read Mappings**. This can be useful in situations where you have
already performed a mapping with one data set, and you receive a second data set that you want to have mapped together with the first one. In this case, you can run a new mapping of the second data set and merge the results:

**Toolbox | Resequencing Analysis | Merge Read Mappings**

This opens a dialog where you can select two or more mapping results, either in the form of tracks or read mappings. If the mappings are based on the same reference sequences (based on the name and length of the reference sequence), the reads will be merged into one mapping. If different reference sequences are used, they will simply be incorporated into the same result file (either a track or a mapping table).

The output from the merge can either be a track or standard mappings (equivalent to the read mapper’s output, see section 25.1). For all the mappings that could be merged, a new mapping will be created. If you have used a mapping table as input, the result will be a mapping table. Note that the consensus sequence is updated to reflect the merge. The consensus voting scheme for the first mapping is used to determine the consensus sequence. This also means that for large mappings, the data processing can be quite demanding for your computer.

### 25.5 Remove Duplicate Mapped Reads

The purpose of this tool is to efficiently remove duplicate reads from a mapping, when duplicate reads have arisen due to the use of PCR amplification (or other enrichment) during sample preparation. This does not mean, however, that this tool should be used on all data that had an amplification step. In fact, use of this tool in the case of RNA-Seq data, amplicon data, or any sample where the start of a large number of reads are purposely at the same reference location, it is not recommended to make use of this tool. The tool may be used on mappings of single end reads, paired end reads or both.

A read duplication can be easily distinguished when mapping reads to a reference sequence as shown in the example in figure 25.38.

---

**Figure 25.38: Mapped reads with a set of duplicate reads, the colors denote the strand (green is forward and red is reverse).**
When sequencing library preparation involves a PCR amplification step, it is common to observe multiple reads where identical nucleotide sequences are disproportionally represented in the final results. Thus, to facilitate processing of mappings based on this kind of data, it may be necessary to perform a duplicate read removal step, which flags identical reads and subsequently removes them from the data set. However, this step is complicated by the low, but consistent, presence of sequencing errors that may cause otherwise identical sequences to differ slightly. Thus, it is important that the duplicate read removal includes some tolerance for nearly identical sequences, which could still be reads from the same PCR artifact.

In samples that have been mapped to a reference genome, duplicate reads from PCR amplification typically result in areas of disproportionally high coverage and are often the cause of significant skew in allelic ratios, particularly when replication errors are made by the enzymes (e.g. polymerases) used during amplification. Sequencing errors incorporated post-amplification can affect both sequence- and coverage-based analysis methods, such as variant calling, where introduced errors can create false positive SNPs, and ChIP-Seq, where artificially inflated coverage can skew the significance of certain locations. By utilizing the mapping information, it is possible to perform the duplicate removal process rapidly and efficiently.

**Note!** We only recommend using the duplicate read removal if there are amplification steps involved in the library preparation. It is not recommended for RNA-Seq data, amplicon data, or any sample where the start of a large number of reads are purposely at the same reference location.

The method used by the duplicate read removal is to identify reads that share common coordinates (e.g. the same start and end coordinate), sequencing direction (or mapped strand) and the same sequence, these being the unifying characteristics behind sequencing reads that originate from the same amplified fragments of nuclear material. However, due to the frequent occurrence of sequencing errors, the tool utilizes simple heuristics to prune sequences with small variations from the consensus, as would be expected from errors observed in data from next-generation sequencing platforms. Base mismatch errors that were incorporated during amplification or prior to amplification will be indistinguishable from SNPs and may not be filtered out by this tool.

### 25.5.1 Algorithm details and parameters

The algorithm operates with the following assumption: Mapped reads from duplicated DNA fragments will share a mapping orientation (e.g. will map to the same strand), and depending on their orientation, will share either a start coordinate (forward reads), an end coordinate (reverse reads) or both (paired end reads).

Based on this assumption, a group of reads that share identical start and end coordinates (or start coordinate and length for single end reads) and also share identical sequences can be considered as potential duplications of the same DNA fragment. These reads are then investigated to find reads to be removed and reads to be kept. In order to explain how this works, we will use a small example shown in figure 25.39.

The example shows 165 reads that share the same start position and orientation and are considered for duplicate read removal. 60 reads share the sequence shown at the top, 5 reads share the middle sequence, and 100 reads share the sequence at the bottom. The differences are at position 3 and 9 (underlined).

The tool will now create a tree structure out of these reads as illustrated in figure 25.40.

The first branch point in the tree is at the third position, where sequence number one has a G
Figure 25.39: An alignment of three different sequence. The numbers are read counts, e.g. the read at the top occurs 60 times.

Figure 25.40: The reads from figure 25.39 represented as a Patricia tree [Morrison, 1968].

and the other sequences have a T. The other two sequence disagree at position nine, where one has a C and another has an A.

The next step is to iteratively merge the branches, starting from the end of the tree. The first branch point to consider is at position nine. Since only 5 reads have a C and 100 reads have an A, the C branch is collapsed. This is shown in figure 25.41.

Figure 25.41: Merging the sequences.

As a user, you can specify the threshold for when the reads should be merged. The default is 20%: when the minority branch has less than 20% of the read count of the both branches, it is collapsed.

The next branch to consider is at the third position, where there are now 105 reads that have a T and 60 reads that have a G (see figure 25.42).

With the default setting at 20%, these two branches will not be collapsed, because there are too many reads on the minority branch (60 reads versus 105 reads). Since this process is aimed at collapsing reads that are only distinguished apart by sequencing errors, you would not expect this situation to be caused by sequencing errors, but rather true biological variation (or PCR errors in the early cycles that are indistinguishable from true variation).

If we raised the threshold to 60%, the two branches above would be merged into one if it was
not for the second rule governing the merging of branches: The sequences have to be identical except for the difference at the branch point. Looking at the sequences in figure 25.42, there is a difference at position 9 which means that these two branches would never be merged, regardless the threshold and the read counts.

The result of the duplicate reads removal in this example would be that the 165 reads are reduced to two in the result.

### 25.5.2 Running the duplicate reads removal

The tool is found in the Toolbox:

**Toolbox | Resequencing Analysis | Remove Duplicate Mapped Reads**

This opens a dialog where you can select mapping results in reads tracks format. Clicking **Next** allows you to set the threshold parameters as displayed in figure 25.43.

The parameter is explained in detail in section 25.5.1.

Clicking **Next** will reveal the output options. The main output is a list of the reads that remain after the duplicates have been removed. In addition, you can get the following output:

**List of duplicate sequences** These are the sequences that have been removed.

**Report** This is a brief summary report with the number of reads that have been removed (see an example in figure 25.44).

**Note!** The Remove Duplicate Mapped Reads tool may run this before or after local realignment. The order in which these two tools are run should make little if any difference.
Extract Consensus Sequence

A consensus sequence can be extracted from all kinds of read mappings, including those generated from de novo assembly or RNA-seq analyses. In addition, you can extract a consensus sequence from nucleotide BLAST results. The consensus sequence extraction tool can be run in batch and as part of workflows.

To start the tool:

Toolbox | Resequenting Analysis | Extract Consensus Sequence

This opens a dialog where you can select mappings, either in the form of tracks or read mappings, or BLAST results. Click Next to specify how the consensus sequence should be created (see figure 25.45).

It is also possible to extract a consensus sequence from a mapping view by right-clicking the name of the consensus or reference sequence or a selection on the reference sequence and select Extract Consensus Sequence.

When extracting a consensus sequence, you can decide how to handle regions with low coverage (a definition of coverage can be found in section 27.1.2). The first step is to define a threshold for when coverage is considered low. The default value is 0, which means that low coverage is defined as no coverage (i.e. no reads align to the reference at this position). That means if you have one read covering a given position, it will only be that read that determines the consensus sequence. If you need more confidence that the consensus sequence is correct, we advise
raising this value. Setting a higher low coverage threshold will require more mapped reads to construct the consensus sequence.

A consensus based on mapped reads cannot be generated in regions that meet or are below the value set for the low coverage threshold, there are several options for handling these low coverage regions:

- **Remove regions with low coverage.** When using this option, no consensus sequence is created for the low coverage regions. There are two ways of creating the consensus sequence from the remaining contiguous stretches of high coverage: either the consensus sequence is split into separate sequence when there is a low coverage region, or the low coverage region is simply ignored, and the high-coverage regions are directly joined (in this case, an annotation is added at the position where a low coverage region is removed in the consensus sequence produced, see below).

- **Insert 'N' ambiguity symbols.** This will simply add Ns for each base in the low coverage region. An annotation is added for the low coverage region in the consensus sequence produced (see below).

- **Fill from reference sequence.** This option will use the sequence from the reference to construct the consensus sequence for low coverage regions. An annotation is added for the low coverage region in the consensus sequence produced (see below).

In addition to deciding how to handle low coverage regions, you can also decide how to handle conflicts or disagreement between the reads when building a consensus sequence in regions above the low coverage threshold:

- **Vote.** Whenever the reads disagree on the base at a given position, the vote resolution will let the majority of the reads decide which base is correct.
  - If the most common symbol is a gap, then the consensus symbol is a gap.
– If there are equal numbers of gaps and non-gaps, then it is one of the other symbols.
– When choosing between symbols we choose in the order A - C - G - T.
– Ambiguous symbols cannot be chosen.

In addition, you can specify to let the voting use the base calling **quality scores** from the reads. This is done by simply adding all quality scores for each base and let the sum determine which one is correct. The base with the highest total quality scores will be chosen. If there are two bases that end up summing to the same total quality score for all reads at that location, A is preferred before C, C before G, and G before T. An annotation with the complete information that was used to resolve the conflict will be added.

- **Insert ambiguity codes.** When this options is selected, read conflicts are addressed by using an ambiguity code representing all read bases represented at the reference location. The problem with the voting option is that it will not be able to represent true biological heterozygous variation in the data. For a diploid genome, if two different alleles are present in an almost even number of reads, only one will be represented in the consensus sequence. With the option to insert ambiguity codes, this can be solved. (The IUPAC ambiguity codes used can be found in Appendix G and F.) However, if an ambiguity code would always be inserted if just one read had a different base, there would be an ambiguity code whenever there was a sequencing error. In high-coverage NGS data that would be a big problem, because sequencing errors would be abundant. To solve this problem, you can specify a **Noise threshold.** The default value for this is 0.1 which means that for a base to contribute to the ambiguity code, it must be in at least 10% of the reads at a given position. The **Minimum nucleotide count** specifies the minimum number of reads that are required before a nucleotide is included. Nucleotides below this limit are considered noise. If no nucleotide passes the noise filters, the position is omitted from the consensus sequence.

- **Use quality score.** The "Use quality score" checkbox option is available for conflicts regardless of whether "Vote" or "Insert ambiguity codes" has been selected. The "Use quality score" checkbox option allows you to use the base calling **quality scores** from the reads. This is done by simply adding all the quality scores for each base and let the sum determine which bases to consider. In other words, if quality scores are used, we will sum the quality score (instead of amount of reads) for each base on each position before applying the noise filters and finally call the consensus symbol.

Click **Next** to set the output option as shown in figure 25.46).

The annotations that can be added to the consensus sequence produced by this tool, show both conflicts that have been resolved and low coverage regions (unless you have chosen to split the consensus sequence). Please note that for large data sets, this can amount to a very high number of annotations, which will cause the tool to take longer to complete, and the result will take up much more disk space.

For stand-alone read mappings, it is possible to transfer existing annotations to the consensus sequence produced. Since the consensus sequence produced may be broken up, the annotations will also be broken up, and may not have the same length as before. In some cases, gaps and low-coverage regions will lead to differences in the sequence coordinates between the input data and the new consensus sequence. The annotations copied will be placed in the region on the consensus that corresponds to the region on the input data, but the actual coordinates might have changed.
Track-based read mappings do not themselves contain annotations and thus the options related to transferring annotations, "Transfer annotations from the reference sequence" and "Keep annotations already on consensus", cannot be selected for this type of input.

Copied/transferred annotations will contain the same qualifier text as the original. That is, the text is not updated. As an example, if the annotation contains 'translation' as qualifier text this translation will be copied to the new sequence and will thus reflect the translation of the original sequence, not the new sequence, which may differ.

The resulting consensus sequence (or sequences) will have quality scores assigned if quality scores were found in the reads used to call the consensus. For a given consensus symbol \( X \) we compute its quality score from the "column" in the read mapping. Let \( Y \) be the sum of all quality scores corresponding to the "column" below \( X \), and let \( Z \) be the sum of all quality scores from that column that supported \( X \).\(^1\) Let \( Q = Z - (Y - Z) \), then we will assign \( X \) the quality score of \( q \) where

\[
q = \begin{cases} 
64 & \text{if } Q > 64 \\
0 & \text{if } Q < 0 \\
Q & \text{otherwise}
\end{cases}
\]

\(^1\)By supporting a consensus symbol, we understand the following: when conflicts are resolved using voting, then only the reads having the symbol that is eventually called are said to support the consensus. When ambiguity codes are used instead, all reads contribute to the called consensus and thus \( Y = Z \).

26.1 Variant Detection tools

CLC Genomics Workbench offers three tools for detecting variants.

- **Fixed Ploidy Variant Detection**  - described in detail in section 26.2
- **Low Frequency Variant Detection**  - described in detail in section 26.3
- **Basic Variant Detection**  - described in detail in section 26.4

They are designed for the analysis of different types of samples and they differ in their underlying assumptions about the data, and hence in their assessments of when there is enough information in the data for a variant to be called. An overview of these differences is given in figure 26.1.

<table>
<thead>
<tr>
<th>Variant caller</th>
<th>Applications</th>
<th>Data</th>
<th>Variant detected</th>
<th>Comments</th>
<th>Examples of recommended applications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fixed Ploidy</td>
<td>Germline variants</td>
<td>A sample for which the ploidy can be assumed known</td>
<td>Will detect variants whose representation in the reads is in accordance with the assumed ploidy</td>
<td>Will discard variants whose representation in the reads is likely due to sequencing errors or mapping artifacts</td>
<td>Germine variant calling</td>
</tr>
<tr>
<td>Low Frequency</td>
<td>Germine and somatic variants</td>
<td>A sample with unknown/assumed ploidy</td>
<td>Will detect variants whose representation in the reads is in accordance with the presence of a variant in a proportion of the reads</td>

Figure 26.1: An overview of the variant detection tools.

To run one of the variant detection tool, go to:

**Toolbox | Resequencing Analysis**

and choose the appropriate tool. In the first dialog of each detection tool, you are asked to specify the reads track or read mapping to analyze. The user is next asked to set the parameters that are specific for the variant detection tool. The three tools, their assumptions, and the tool-specific parameters are described later in their respective sections.

All variant detection tools will call:
• SNVs - single nucleotide variants
• MNVs - neighboring SNVs, where there is evidence they occur together
• small to medium-sized insertions and deletions - insertions and deletions fully represented within a single read
• replacements - neighboring SNVs and insertions or deletions

26.1.1 Differences in the variants called by the different tools

Because the tools differ in their underlying assumptions about the data, different variants may be called on the same data set using the same filter settings (see section 26.6). In general,

- the Basic Variant Detection tool calls the highest number of variants. It runs relatively quickly because it does not do any error-model estimation.

- the Low Frequency Variant Detection tool calls only a subset of the variants called by the Basic Variant Detection tool. The variants called by the Basic Variant Detection tool but not called by the Low Frequency Variant Detection tool usually originate from sequencing errors. The Low Frequency Variant Detection tool is the slowest of the three variant callers as it estimates an error-model and does not just consider variants within a specified ploidy model.

- the Fixed Ploidy Variant Detection tool calls a subset of the variants called by the Low Frequency Variant Detection tool. The variants called by the Low Frequency Variant Detection tool but not called by the Fixed Ploidy Variant Detection tool likely originate from mapping or sequencing errors.

The following examples show a Track list view of the variants detected by the three different variant detection tools for a particular data set with the same filter settings. The top three variant tracks contain the results of the variant detection tools. The numbers of variants called are shown on the left side in brackets under the variant track names. The track ‘basicV2’ contains the results of the Basic Variant Detection tool, the track ‘LowFreq’ contains the results of the Low Frequency Variant Detection tool and the track ‘FixedV2’ contains the results of the Fixed Ploidy Variant detection tool. The other variant tracks display comparisons between results of the different tools. The particular comparisons is described in the name of each of these tracks.

Figure 26.2 highlights a variant reported by the Basic Variant Detection tool but not by the other variant detection tools. The information in the table view of the Basic Variant Detection results track (‘basicV2’) reveals that the variant is present at a low frequency (3 reads) in a high coverage position (209 reads), suggesting that is not a true variant but rather a sequencing error.

Figure 26.3 shows variant calls produced by the three variant detection tool with the same data and general filter settings. As expected, the Basic Variant Detection tool reports the most variants (884), the Fixed Ploidy reports the fewest (233), and the Low Frequency Variant Detection tool detects a number between these two (796). But note that in the track named ‘inLowFreqV2-notInBasicV2’ that there are 9 variants reported by the Low Frequency Variant Detection tool that are not reported by the Basic Variant detection tool. It is because these variants are considered as several SNVs by the Low Frequency Variant Detection tool when they were part of a more complex MNV in the Basic Variant Detection results. In the case of the variant highlighted in
Figure 26.2: Case where a variant is detected only using the Basic Variant Detection tool.

Figure 26.3: The Low Frequency Variant Detection calls for one variant in results track ('lowFreq'), while the Basic Variant Detection called a heterozygous 2 bp MNV in results track ('basicV2'). Here, the Low Frequency Variant Detection tool called only one of the two SNVs of that MNV. The second SNV of the MNV was not deemed to be supported by the evidence in the data when error modelling was carried out and so was not reported.

Figure 26.3: Case where variants can be detected as SNV by a tool and MNV by another.
Figure 26.4 shows a variant that is detected by both the Basic and the Low Frequency Variant Detection tools, but not by the Fixed Ploidy Variant Detection tool when a ploidy of 2 was specified. The information in the table view of the Low Frequency Variant Detection results track ('lowFreq') reveals that the highlighted variant is present in 29 reads in an area with coverage 204, a ratio inconsistent with what can be expected from a diploid sample, thus preventing the stringent Fixed Ploidy Variant Detection tool to call it as a variant. It is also unlikely that this variant was caused by sequencing error. The most likely explanation for the presence of this variant is that it originated from an error in the mapping of the reads. This happens if reads are mapped to a reference area that does not represent their true source, using for example an incomplete reference or one from a too distantly related organism.

Figure 26.4: Case where a variant does not fit the ploidy assumption.
26.1.2 How the variant detection tools work

Each variant detection tool operates in a similar fashion, following successive and iterative steps while using common filters to call for variants. Before you start the tool, the wizard will take you through the different filters you can set to define which of the single polymorphisms detected should be called as a variant. The following sections describe the individual characteristics and the specific assumptions of the three variant detection tools. The filtering and output options common to the tools are described in detail in section 26.6 and section 26.7.

The steps of the Variant Detection tools are as follow:

1. The tool identifies all possible variants from either the total input dataset or a subset of it, depending on how the following filters have been set:
   - **Reference masking** settings select the areas of the mapping that should be inspected for variants.
   - **Read filter** settings select for the reads that should be considered in the assessment.
   - **Count and coverage filters** select for sites meeting coverage, frequency and absolute count requirements set for the analysis. Half the value of each parameter is used during the first stage of variant detection, when single position variants are initially being considered. This ensures that multiple position variants, which are built up from the single position variants, are not missed due to too stringent filtering early on. The full values for the cut-offs are applied later during the variant detection process.
   - **Noise filters** specify requirements for a read to be included, considering the quality and neighborhood composition of the area surrounding a potential variant.

2. At this stage, for the Fixed Ploidy and Low Frequency Variant Detection tools only, site-specific information is used to iteratively estimate error models. These error models are then used to distinguish true variants from likely sequencing errors. Potential single nucleotide variants are only be kept if the model containing the variant is significantly better than the model without the variant. Full details for the Fixed Ploidy Variant Detection tool are given in section 26.2 and 26.3.

3. The tool checks each position for other features such as read direction, base qualities and so on using the cut-off values specified in the **Noise filters** (see section 26.6).

4. The tool checks for complex variants by taking the single position variants identified in the steps above and checking if neighboring variants are present in the same read. If so, the tool ‘joins’ these SNVs into MNVs, longer insertions or deletions, or into replacements. Note that SNVs are joined only when they are present in the same read as this provides evidence that the variants appear contiguously in the sample.

5. Finally the tool applies the full cut-off values supplied for the **Count and coverage filters** to the single and multiple position variants obtained during the previous step.

26.1.3 Detailed information about overlapping paired reads

Paired reads that overlap introduce additional complexity for variant detection. This section describes how this is handled by **CLC Genomics Workbench**.
When it comes to coverage in the overlapping region, each pair is contributing once to the coverage. Even if there are indeed two reads in this region, they do not both contribute to coverage. The reason is that the two reads represent the same fragment, so they are essentially treated as one.

When it comes to counting the number of forward and reverse reads, including the forward/reverse reads balance, each read contribute. This is because this information is intended to account for systematic sequencing errors in one direction, and the fact that the two reads are from the same fragment is less important than the fact that they are sequenced on different strands.

If the two overlapping reads do not agree about the variant base, they are both ignored. Please note that there can be a special situation with the basic variant detection: If the two reads disagree, and one read does not pass the quality filter, the other read will contribute to the variant just as if there had been only that read and no overlapping pair.

### 26.2 Fixed Ploidy Variant Detection

The Fixed Ploidy Variant Detection tool relies on two models:

1. A model for the possible 'site-types' depends on the user-specified ploidy parameter: For a diploid organism there are two alleles and thus the site types are A/A, A/C, A/G, A/T, A/-, C/C, and so on until -/-.  
2. A model for the sequencing errors that specifies the probabilities of having a certain base in the read but calling a different base. The error model is estimated from the data prior to calling the variants (see section 26.5).

The Fixed Ploidy algorithm will, given the estimated error model and the data observed in the site, calculate the probabilities of each of the site types. One of those site types is the site that is homozygous for the reference - that is, it stipulates that whatever differences are observed from the reference nucleotide in the reads is due to sequencing errors. The remaining site-types are those which stipulate that at least one of the alleles in the sample is different from the reference. The sum of the probabilities for these latter site types is the posterior probability that the sample contains at least one allele that differs from the reference at this site. We refer to this posterior probability as the 'variant probability'.

The Fixed Ploidy Variant Detection tool has two parameters: the 'Ploidy' and the 'Variant probability' parameters (figure 26.5):

- The 'ploidy' is the ploidy of the analyzed sample. The value that the user sets for this parameter determines the site types that are considered in the model. For more information about ploidy please see section 26.2.1.
- The 'Required variant probability' is the minimum probability value of the 'variant site' required for the variant to be called. Note that it is not the minimum value of the probability of the individual variant. For the Fixed Ploidy Variant detector, if a variant site - and not the variant itself - passes the variant probability threshold, then the variant with the highest probability at that site will be reported even if the probability of that particular variant might be less than the threshold. For example if the required variant probability is set to 0.9 then the individual probability of the variant called might be less than 0.9 as long as the probability of the entire variant site is greater than 0.9.
As the Fixed Ploidy Variant Detection tool strongly depends on the model assumed for the ploidy, the user should carefully consider the validity of the ploidy assumption that he makes for his sample. The tool allows ploidy values up to and including 4 (tetraploids). For higher ploidy values the number of possible site types is too large for estimation and computation to be feasible, and the user should use the Low Frequency or Basic Variant Detection Tool instead.

### 26.2.1 Ploidy and sensitivity

The Fixed Ploidy Variant Detection tool has two parameters. The ploidy level you set defines the statistical model that will be used during the variant detection analysis and thereby also defines what will be reported. The number of alleles that variant may have depends on the value that has been chosen for the ploidy parameter. For example, if you chose a ploidy of 2, then the variant at a site could be a homozygote (two alleles the same in the sample, but different to the reference), or a heterozygote (two alleles different than each other in the sample, with at least one of them different from the reference). If you had chosen a ploidy of three, then the variant at a site could be a homozygote (three alleles the same in the sample, but different to the reference), or a heterozygote (three alleles different than each other in the sample, with at least one of them different from the reference).

The variant probability parameter defines how good the evidence has to be at a particular site for the tool to report a variant at that location. If the site passes this threshold, then the variant with the highest probability at that site will be reported.

Sensitivity of the tool can be altered by changing these parameters: to increase sensitivity, you could decrease the variant probability setting - more sites are being reported - or increase the ploidy - adding extra allele types.

For example, a sample with a ploidy of 2 has many C and a few G at a particular location where the reference is a T. There is high enough evidence that the actual position is different than the reference, so the variant at this location will be reported. In the diploid model, all the possibilities will have been tested (e.g. A|A, A|C,...C|C, C|G, C|T,...and so on). In this example, C|C had the highest probability, and as long as the relative prevalence of Gs is low compared to Cs - that is, the probability of C|C stays higher than C|G - C|C will be reported. But in a case where the sample has a ploidy of 3, the model will test all the triploid possibilities (e.g. A|A|A, A|A|C, A|A|G,...C|C|A, C|C|C, C|C|G,... and so on). For the same site, if the evidence in the reads results in the variant C|C|G having a higher probability than C|C|C, then it would be the variant reported. This shows that by increasing ploidy we have increased sensitivity of the tool, reporting a variant that represents the reads with G as well as the ones reporting a C at a particular position.
26.3 Low Frequency Variant Detection

As the Fixed Ploidy Variant Detection tool, the Low Frequency Variant Detection tool relies on

1. A statistical model for the analyzed sample and
2. A model for the sequencing errors.

A statistical test is performed at each site to determine if the nucleotides observed in the reads at that site could be due simply to sequencing errors, or if they are significantly better explained by there being one (or more) alleles. If the latter is the case, a variant corresponding to the significant allele will be called with an estimated frequency.

The Low Frequency Variant Detection tool has one parameter (figure 26.6):

- **Required Significance**: this parameter determines the cut-off value for the statistical test for the variant not being due to sequencing errors. Only variants that are at least this significant will be called. The lower you set this cut-off, the fewer variants will be called.

The Low Frequency Variant Detection tool is suitable for analysis of samples of mixed tissue types (such as cancer samples) in which low frequent variants are likely to be present, as well as for samples for which the ploidy is unknown or not well defined. The tool also calls more abundant variants, and can be used for analysis of samples with ploidy larger than four. Note that, as the tool looks for all variants, abundant as well as low frequency ones, analysis will generally be slower than those of the other variant detection tools. In particular it will be very slow - possibly prohibitively so - for samples with extremely high coverage, or a very large number of variants (as in cases where the sample differs considerably from the reference).

![Figure 26.6: The Low Frequency Variant Detection parameters.](image)

For a more in depth description of the Low Frequency Variant Detection tool see section 26.8.

26.4 Basic Variant Detection

The Basic Variant Detection tool does not rely on any assumptions on the data, and does not estimate any error model. It can be used on any type of sample. It will call a variant if it satisfies the requirements that you specify when you set the filters (see section 26.6). The tool has a single parameter (figure 26.7) that is specific to this tool: the user is asked to specify the 'ploidy' of the sample that is being analyzed. The value of this parameter does not have an impact on which variants are called - it will merely determine the contents of the 'hyper-allelic' column that is added to the variant track table: variants that occur in positions with more variants than
expected given the specified ploidy, will have 'Yes' in this column, other variants will have 'No' (see section 26.7 for a description of the outputs).

26.5 Variant Detection - error model estimation

The Fixed Ploidy and Low Frequency Variant Detection tools both rely on statistical models for the sequencing error rates. An error model is assumed and estimated for each quality score. Typically low quality read nucleotides will have a higher error rate than high quality nucleotides. In the error models, different types of errors have their own parameter, so if A’s for example more often tend to result in erroneous G’s than other nucleotides, that is also recognized by the error models. The parameters are all estimated from the data set being analyzed, so will adapt to the sequencing technology used and the characteristics of the particular sequencing runs. Information on the estimated error rates can be found in the Reports (see section 26.7 and figure 26.8).

Number of sequenced bases with quality scores 20-29: 382,854,867

Figure 26.8: Example of estimated error rates estimated from a whole exome sequencing Illumina data set.

The figure shows average estimated error rates across bases in the given quality score intervals.
(20-29 and 30-39, respectively). As expected, the estimated error rates (that is, the off-diagonal elements in the matrices in the figure) are higher for bases with lower quality scores. Note also that although the matrices in the figure show error rates of bases within ranges of quality scores, a separate matrix is estimated for each quality score in the error model estimation.

### 26.6 Variant Detection - filters

The variant detectors offer a number of filters for which the user will set values in two wizard steps, the ‘General filters’ and the ‘Noise filters’. Note that the tools add for most filters the values calculated and the bases filtered on as annotations to the variants (see section 26.7). This means that the filtering information is available in the variant track and that the user can choose to perform the filtering in a post-processing step from the variant track table rather than applying the filtering during the variant calling detection step.

The filters are described below.

#### 26.6.1 General filters

The General filters relate to the regions and reads in the read mappings that should be considered, and the amount of evidence the user wants to require for a variant to be called (figure 26.9):

![General filters](image)

Figure 26.9: General filters. The values shown are those that are default for Fixed Ploidy Variant detection.

**Note on the use of the Low Frequency Variant Detection tool with Whole Genome Sequencing data:** The default settings for the Low Frequency Variant Detection tool are optimized for targeted resequencing protocols, and NOT whole genome sequencing (e.g. cancer gene panels) where it is not uncommon to have modest coverage for most part of the mapping, and abnormal areas (typically repeats around the centromeres) with very high coverage. Looking for low frequency variants in high coverage areas will exhaust the machine memory because there will be many low frequency variants due to some reads originating from near identical repeat sequences or simple sequencing errors. In order to run the tool on WGS data the parameter **Ignore positions with coverage above** should be adjusted to a lower number (typically 1000).
Reference masking

The 'Reference masking' filters allow the user to only perform variant calling (including error model estimation) in specific regions. In addition to selecting an annotation track, there are two parameters to specify:

- **Ignore positions with coverage above**: All positions with coverage above this value will be ignored when inspecting the read mapping for variants. The option is highly useful in cases where you have a read mapping which has areas of extremely high coverage as are areas around centromeres in whole genome sequencing applications for example.

- **Restrict calling to target regions**: Only positions in the regions specified will be inspected for variants.

Read filters

The Read filters determine which reads (or regions) should be considered when calling the variants.

- **Ignore broken pairs**: When ticked, reads from broken pairs are ignored. Broken pairs may arise for a number of reasons, one being erroneous mapping of the reads. In general, variants based on broken pair reads are likely to be less reliable, so ignoring them may reduce the number of spurious variants called. However, broken pairs may also arise for biological reasons (e.g. due to structural variants) and if they are ignored some true variants may go undetected. Please note that ignored broken pair reads will not be considered for any non-specific match filters.

- **Non-specific match filter**: Non-specific matches are likely to come from repeat region whose exact mapping location is uncertain. In general, variants based on non-specific matches are likely to be less reliable. However, as there are regions in the genome that are entirely perfect repeats, ignoring non-specific matches may have the effect that true variants go undetected in these regions.

There are three options for specifying to which 'extent' the non-specific matches should be ignored:

- 'No': they are not ignored.
- 'Reads': they are ignored.
- 'Region': when this option is chosen no variants are called in regions covered by at least one non-specific match. In this case, the minimum length of reads that are allowed to trigger this effect has to be stated, as really short reads will usually be non-specific even if they do not stem from repeat regions.

Coverage and count filters

These filters specify absolute requirements for the variants to be called. Note that suitable values for these filters are highly dependent on the coverage in the sample being analyzed:

- **Minimum coverage**: Only variants in regions covered by at least this many reads are called.
• **Minimum count**: Only variants that are present in at least this many reads are called.

• **Minimum frequency**: Only variants that are present at least at the specified frequency (calculated as ‘count’/’coverage’) are called.

These values are calculated for each of the detected candidate variants. If the candidate variant meets the specified requirements, it is called. Note that when the values are calculated, only the 'countable reads' - the reads chosen by the user to NOT be ignored - are considered. For example, if the user had specified to ignore reads from broken pairs, they will not be countable. This is also the case for non-specific reads, and for reads with bases at the variant position that does not fulfill the base quality requirements specified by the 'Base Quality Filter' (see the section on 'Noise filters' below). Also note that overlapping paired reads only count as one read since they only represent one fragment.

### 26.6.2 Noise filters

The 'Noise filters’ examine each candidate variant at a more detailed level and filter out those that are likely the result of systematic errors and/or biases, such as those coming from samples preparation steps or sequencing protocol (figure 26.10). These filters should be used with care as there is always the risk of not calling a real variant that has the characteristics of a systematically induced one.

![Noise filters](image)

**Figure 26.10: Noise filters.**

### Quality filters

• **Base quality filter**: The base quality filter can be used to ignore the reads whose nucleotide at the potential variant position is of dubious quality. This is assessed by considering the quality of the nucleotides in the region around the nucleotide position. There are three parameters to determine the base quality filter:
- **Neighborhood radius**: This parameter determines the region size. For example if a neighborhood radius of five is used, a nucleotide will be evaluated based on the nucleotides that are 5 positions upstream and 5 positions downstream of the examined site, for a total of 11 nucleotides. Note that, near the end of the reads, eleven nucleotides will still be considered by offsetting the region relative to the nucleotide in question.

- **Minimum central quality**: Reads whose central base has a quality below the specified value will be ignored. This parameter does not apply to deletions since there is no ‘central base’ in these cases.

- **Minimum neighborhood quality**: Reads for which the minimum quality of the bases is below the specified value will be ignored.

Figure 26.11 gives an example of a variant called when the base quality filter is NOT applied, and not called when it is. When switching on the 'Show quality scores' option in the side panel of the reads it becomes visible that the reads that carry the potential 'G' variant tend to have poor quality. Note that the error in the example shown is a 'typical' Illumina error: the reference has a 'T' that is surrounded by stretches of 'G', the 'G' signals 'drowning' the signal of the 'T'. As all reads that have a base with quality less than 20 in this potential variant position are ignored when the 'Base quality filter' is turned on, no variant is called, most likely because it now does not meet the requirements of either the 'Minimum coverage', 'Minimum count' or 'Minimum frequency' filters.

![Figure 26.11](image)

Figure 26.11: Example of a variant called when the base quality filter is NOT applied, and not called when it is.

**Direction and position filters**

Many sequencing protocols are prone to various types of amplification induced biases and errors. The 'Read direction' and 'Read position' filters are aimed at providing means for weeding out variants that are likely to originate from such biases.
• **Read direction filter:** The read direction filter removes variants that are almost exclusively present in either forward or reverse reads. For many sequencing protocols such variants are most likely to be the result of amplification induced errors. Note, however, that the filter is **NOT suitable for amplicon data**, as for this you will not expect coverage of both forward and reverse reads. The filter has a single parameter:

  - **Direction frequency:** Variants that are not supported by at least this frequency of reads from each direction are removed.

• **Relative read direction filter:** The relative read direction filter attempts to do the same thing as the 'Read direction filter', but does this in a statistical, rather than absolute, sense: it tests whether the distribution among forward and reverse reads of the variant carrying reads is different from that of the total set of reads covering the site. The statistical, rather than absolute, approach makes the filter less stringent. The filter has one parameter:

  - **Significance:** Variants whose read direction distribution is significantly different from the expected with a test at this level are removed. The lower you set the significance cut-off, the fewer variants will be filtered out.

• **Read position filter:** The read position filter is a filter that attempts to remove systematic errors in a similar fashion as the 'Read direction filter', but that is also **suitable for hybridization-based data**. It removes variants that are located differently in the reads carrying it than would be expected given the general location of the reads covering the variant site. This is done by categorizing each sequenced nucleotide (or gap) according to the mapping direction of the read and also where in the read the nucleotide is found; each read is divided in five parts along its length and the part number of the nucleotide is recorded. This gives a total of ten categories for each sequenced nucleotide and a given site will have a distribution between these ten categories for the reads covering the site. If a variant is present in the site, you would expect the variant nucleotides to follow the same distribution. The read position filter carries out a test for whether the read position distribution of the variant carrying reads is different from that of the total set of reads covering the site. The filter has one parameter:

  - **Significance:** Variants whose read position distribution is significantly different from the expected with a test at this level, are removed. The lower you set the significance cut-off, the fewer variants will be filtered out.

Figure 26.12 shows an example of a variant that is removed by the 'Read direction' filter. To see the direction of the reads, you must adjust the viewer settings in the 'Reads track' side panel to 'Disconnect paired reads'. Note that variant calling was done ignoring non-specific matches and broken pair reads, so only the 16 intact forward paired reads (the green reads) are considered. In this example there was no intact reverse reads.

Figure 26.13 shows an example of a variant that is removed by the 'Read position' filter, but not by the 'Read direction' filter. This variant is only seen in a set of reads having a similar start position, while reads that start in a different location do not contain this variant (e.g., none of the reads that start after position 186,641,600 carry the variant). This could indicate the incorporation of an incorrect base during the library preparation process rather than a true biological variant. The purpose of the 'Read position' filter is to reduce the presence of these types of variants. As with all noise filters, the more stringent the setting, the more likely you are
to remove false positives and enrich your result for true positive variant calls but comes with the risk of filtering out true positives as well.

Understanding the type of false positive this filter is intended to remove will help you to determine what makes sense for your data set. For example, if your sequencing data did not include a PCR step or hybrid capture step, you may wish to use more lax settings for this filter (or not use it at all).

Figure 26.13: A variant that is filtered out by the Read position filter but not by the Read direction filter.
CHAPTER 26. VARIANT DETECTION

Technology specific filters

- **Remove pyro-error variants:** This filter can be used to remove insertions and deletions in the reads that are likely to be due to pyro-like errors in homopolymer regions. There are two types of such errors: They may occur either at (1) the immediate ends of homopolymer regions or (2) as an 'overspill' a few nucleotides downstream of a homopolymer region. In case (1) the exact numbers of the same number of nucleotide is uncertain and a sequence like "AAAAAAA" is sometimes reported as "AAAAAAAGA". In case (2) a sequence like "CGAAAAAGTCG" may sometimes get an 'overspill' insertion of an A between the T and C so that the reported sequence is C "CGAAAAAGTACG". Note that the removal is done in the reads as a very first step, before calling the initial 1 bp variants.

There are two parameters that must be specified for this filter:

- **In homopolymer regions with minimum length:** Only insertion or deletion variants in homopolymer regions of at least this length will be removed.
- **With frequency below:** Only insertion or deletion variants whose frequency (ignoring all non-reference and non-homopolymer variant reads) is lower than this threshold will be removed.

Note that the higher you set the With frequency below parameter, the more variants will be removed. Figure 26.14 shows an example of a variant that is called when the pyro-error filter with minimum length setting 3 and frequency setting 0.5 is used, but that is filtered when the frequency setting is increased to 0.8. The variant has a frequency of 55.71.

In addition to the example above, a simple example is provided below in figure 26.15 to illustrate the difference between variant frequency and pyro-variant removal frequency (where non-reference and non-homopolymer variant reads are ignored).

The read with the T variant is not counted when calculating the frequency for the homopolymer deletion, because we only want to estimate how often a homopolymer variant appears for a given allele, and the T read is not from the same allele as the A and gap reads.

For the deletion, the variant frequency will be 50 percent, if it is reported. This is because it appears in 3 of 6 reads.

However, the pyro-variant removal frequency is 0.6, because it appears in 3 of 5 reads that come from the same allele. Thus the deletion will only be removed by the pyro-filter if the With frequency below parameter is above 0.6 and the In homopolymer regions with minimum length parameter is less than 7.

26.7 Variant Detection - the outputs

The Variant Detection Tools have the following outputs: a variant track, an annotated variant table and a report (figure 26.16). The report contains information on the estimated error model and, as only the Fixed ploidy and the Low Frequency Variant Detection tool uses an error model, the report is only available for those, and not for the Basic Variant Detection tool. The outputs are described below.
CHAPTER 26. VARIANT DETECTION

26.7.1 The variant track output

The variant track contains information on each of the variants called, including reference alleles. When opened in the table view there is a number of columns for each of the variants (see figure 26.17).

The contents of these are explained in section 26.9.1, except for the following:

Figure 26.14: An example of a variant that is filtered out when the pyro-error filter is applied with settings 3 and 0.8, but not with settings 3 and 0.5.

Figure 26.15: An example of a simple read mapping with 6 mapped reads. Three of them indicate a deletion, two match the reference, and one read is an A to T SNP
**Probability** The contents of the Probability column (for Low Frequency and Fixed Ploidy Variant Detection tool only) depend on the variant detection tool that produced and the type of variant:

- In the Fixed Ploidy Variant Detection Tool, the probability in the resulting variant track’s 'Probability' column is NOT the probability referred to in the wizard. The probability referred to in the wizard is the required minimum (posterior) probability that the site is NOT homozygous for the reference. The probability in the variant track 'Probability' column is the posterior probability of the particular site-type called. The fixed ploidy tool calculates the probability of the different possible configurations at each site. So using this tool, for single site variants the probability column just contains this quantity (for variants that span multiple positions see below).

- The Low Frequency Variant Detection tool makes statistical tests for the various possible explanations for each site. This means that the probability for the called variant must be estimated separately since it is not part of the actual variant calling. This is done by assigning prior probabilities to the various explanations for a site in a way that makes the probability for two explanations equal in exactly the situation where the statistical test shifts from preferring one explanation to the other. For a given single site variant, the probability is then calculated as the sum of probabilities for all the explanations containing that variant. So if a G variant is called, the reported probability is the sum of probabilities for these configurations: G, A/G, C/G, G/T, A/C/G, A/G/T, C/G/T, and A/C/G/T (and also all the configurations containing deletions together with G).

For multi position variants, an estimate is made of the probability of observing the same read data if the variant did not exist and all observations of the variant were due to sequencing errors. This is possible since a sequencing error model is found for both the fixed ploidy and rare variant tools. The probability column contains one minus this
estimated probability. If this value is less than 50%, the variant might as well just be the result of sequencing errors and it is not reported at all.

**Read count** The number of ‘countable’ reads supporting the allele. Only ‘countable’ reads are considered (see under ‘Count’ above for an explanation of ‘countable’ reads). Note that each read in an overlapping pair contribute 1. To view the reads in pairs in a reads track as single reads, check the ‘Disconnect paired reads’ option in the side-panel of the reads track. (Please see the column ‘Count’ above for a column that reports the value for ‘fragments’ rather than for ‘reads’).

**Read coverage** The read coverage at this position. Only ‘countable’ reads are considered (see under ‘Count’ above for an explanation of ‘countable’ reads). Note that each read in an overlapping pair contribute 1. To view the reads in pairs in a reads track as single reads, check the ‘Disconnect paired reads’ option in the side-panel of the reads track. (Please see the column ‘Coverage’ above for a column that reports the value for ‘fragments’ rather than for ‘reads’).

**# Unique start positions** The number of unique start positions for ‘countable’ fragments that support the variant. This value can be important to look at in cases with low coverage. If all reads supporting the variant have the same start position, you could suspect that it is a result of an amplification error.

**# Unique end positions** The number of unique end positions for ‘countable’ fragments that support the variant. This value can be important to look at in cases with low coverage. If all reads supporting the variant have the same end position, you could suspect that it is a result of an amplification error.

**BaseQRankSum** The BaseQRankSum column contains an evaluation of the quality scores in the reads that have a called variant compared with the quality scores of the reference allele. Reference alleles and variants for which no corresponding reference allele is called do not have a BaseQRankSum value. The score is a z-score derived using the Mann-Whitney U test, so a value of -2.0 indicates that the observed qualities for the variant are two standard deviations below what would be expected if they were drawn from the same distribution as the reference allele qualities. A negative BaseQRankSum indicates a variant with lower quality than the reference variant, and a positive z-score indicates higher quality than the reference.

**Read position test probability** The test probability for the test of whether the distribution of the read positions variant in the variant carrying reads is different from that of all the reads covering the variant position.

**Read direction test probability** Tests whether the distribution among forward and reverse reads of the variant carrying reads is different from that of all the reads covering the variant position. This value reflects a balanced presence of the variant in forward and reverse reads (1: well-balanced, 0: un-balanced). This p-value is based on a statistic that we assume follows a Chi-square(df=2) distribution under the null hypothesis of the variant having equal frequency on reads from both direction. Note that GATK uses a Fisher’s exact test for the same purpose. The difference between both approaches lead to a potential overestimation of p-values output by the workbench’s variant detection tools.

**Hyper-allelic** Basic and Fixed Ploidy Variant detectors only: Contains "yes", if the site contains more variants than the user-specified ploidy predicts, "no" if not.
**Genotype** Fixed Ploidy only: Contains the most probable genotype for the site.

**Homopolymer** The column contains "Yes" if the variant is likely to be a homopolymer error and "No" if not. This is assessed by inspecting all variants in homopolymeric regions longer than 2. A variant will get the mark "yes" if it is a homopolymeric length variation of the reference allele, or a length variation of another variant that is a homopolymeric variation of the reference allele. When several overlapping homopolymeric variants are identified, all except the most frequent are marked as being homopolymer. However, if one of the overlapping, homopolymeric variants is the reference allele, then all of them are marked as homopolymer.

**QUAL** Measure of the significance of a variant, i.e., a quantification of the evidence (read count) supporting the variant, relative to the coverage and what could be expected to be seen by chance, given the error rates in the data. The mathematical derivation of the value depends on the set of probabilities of generating the nucleotide pattern observed at the variant site (1) by sequencing errors alone and (2) under the different allele models of the variant caller allows. Qual is calculated as $-10 \log_{10}(1-p)$, $p$ being the probability that a particular variant exists in the sample. Qual is capped at 200 for $p=1$, with 200: highly significant, 0: insignificant. In rare cases, the Qual value cannot be calculated for specific variant and as a result the Qual field will be empty. This value is necessary for certain downstream analyses of the data after export in vcf format. A QUAL value of 10 indicates a 1 in 10 chance that the called variant is an error, while a QUAL of 100 indicates a 1 in $10^{10}$ chance that the called variant is an error.

### 26.7.2 The annotated table output

The ‘Annotated table’ contains only non-reference alleles. For a detailed description of the output, please see section 26.9.2.

### 26.7.3 The variant detection report

In addition to the estimated error rates of the different types of errors shown in figure 26.8, the report contains information on the total error rates for each quality score as well as a distribution of the qualities of the individual bases in the reads in the read mapping, at the sites that were examined for variants (see figure 26.18).

### 26.8 Fixed Ploidy and Low Frequency Detection tools: detailed descriptions

This section provides a detailed description of the models, methods and estimation procedures behind the Fixed Ploidy and Low Frequency Variant Detection tools. For less detailed descriptions please see sections Section 26.2 and Section 26.3.

#### 26.8.1 The Fixed Ploidy Variant Detection tool: Models and methods

This section describes the model, method and estimation procedure behind the Fixed Ploidy Variant Detection tool. The Fixed Ploidy Variant Detection tool is designed for detecting variants in samples for which the ploidy is known. As the Fixed Ploidy Variant Detection tool assumes,
and hence can exploit, information about underlying possible allele type sites, this variant caller has particularly high specificity for samples for which the ploidy assumption is valid.

The Fixed Ploidy Variant Detection tool

The purpose of the Fixed Ploidy Variant Detection tool is to call variants in samples with known ploidy from read mapping data. It can detect variants in samples from haploid (e.g. bacteria), diploid (e.g. human) and polyploid (upto tetraploid) organisms (e.g. higher plants). It detects Single Nucleotide Variants (SNVs), MNVs (Multiple Nucleotide Variants), insertions, deletions as well as replacements (combinations of neighboring insertions, deletions and SNVs for which the positions are ambiguous).

The algorithm behind the Fixed Ploidy Variant Detection tool combines a Bayesian model with a Maximum Likelihood approach. Variants are called by examining the posterior probabilities from the Bayesian model: at any given site a variant is called if the sum of the posterior probabilities of
the site types that are different from the homozygous reference allele site type is larger than the user-specified 'probability' cut-off value. The variant called is the variant that corresponds to the site type with the highest posterior probability. When evaluating the posterior probabilities in the Bayesian model, maximum likelihood estimates for the parameters of the model are used. These are obtained from the likelihood function using an Expectation Maximization (EM) approach.

The model for the Fixed Ploidy Variant Detection tool

The statistical model for the Fixed Ploidy Variant Detection tool consists of a model for the possible site types, $S$, and their prior probabilities, $f_s, s \in S$, and for the sequencing errors, $e$.

Prior site type probabilities: The set of possible site types is determined entirely by the assumed ploidy, and consists of the set of possible underlying nucleotide allele combinations that can exist within an individual with the specified number of alleles. E.g. if the specified ploidy is 2, the individual has two alleles, and the nucleotide at each allele can either be an A, a C, a G, a T or a −. The set of possible types for the diploid individual’s sites is thus:

Note that, as we cannot distinguish the alleles from each other there are not $5 \times 5 = 25$ possible site types, but only 15 (that is, the allele combination A/C is indistinguishable from the allele combination C/A).

We let $f_s$ denote the prior probabilities of the site types $s \in S$. The prior probabilities of the site types are the frequencies of the true site types in the mapping. The values of these are unknown, and need to be estimated from the data.

Error probabilities: The model for the sequencing errors describes the probabilities with which the sequencing machine produces the nucleotide $M$, when what it should have produced was the nucleotide $N$, ($M$ and $N \in \{A,C,G,T,\}$. When quality values are available for the nucleotides in the reads, we let each quality value have its own error model; if not, a single model is assumed for all nucleotides. Each error model has the following 25 parameters:

$$\{e(N \rightarrow M) | N, M \in \{A,C,G,T,\} \}.$$ 

The values of these parameters are also unknown, and hence also need to be estimated from the data.

Deriving the posterior probabilities of the site types

We will call a variant at a site if the sum of the posterior probabilities of the non-homozygous reference site types is larger than the user-specified cut-off value. For this we need to be able to calculate the posterior site type probabilities. We here derive the formula for these.

Using the Bayesian approach we can write the posterior probability of a site type, $t$, as follows:

$$P(t|\text{data}) = \frac{P(\text{data}|t)P(t)}{P(\text{data})} = \frac{P(\text{data}|t)P(t)}{\sum_{s \in S} P(\text{data}|s)P(s)}, \quad (26.1)$$
where \( P(t) \) is the prior probability of site type \( t \) (that is, \( f_s, s \in S \), from above) and \( P(\text{data}|t) \) is the likelihood of the data, given the site type \( t \). The data consists of all the nucleotides in all the reads in the mapping. For a particular site, assume that we have \( k \) reads that cover this site, and let \( i \) be an index over the nucleotides observed, \( n_i \), in the reads at this site. We thus have:

\[
P(\text{data}|t) = P(n_1, ..., n_k|t).
\]

To derive the likelihood of the data, \( P(n_1, ..., n_k|t) \), we first need some notation: For a given site type, \( t \), let \( P_t(N) \) be the probability that an allele from this site type has the nucleotide \( N \). The \( P_t(N) \) probabilities are known and are determined by the ploidy: For a diploid organism, \( P_t(N) = 1 \) if \( t \) is a homozygous site and \( N \) is one of the alleles in \( t \), whereas it is 0.5 if \( t \) is a heterozygous and \( N \) is one of the alleles in \( t \), and it is 0, if \( N \) is not one of the alleles in \( t \). For a triploid organism, the \( P_t(N) \) will be either 0, 1/3, 2/3 or 1.

With this definition, we can write the likelihood of the data \( n_1, ..., n_k \) in a site \( t \) as:

\[
P(n_1, ..., n_k|t) = \prod_{i=1}^{k} \sum_{N \in \{A,C,G,T,-\}} P_t(N) \times e_q(N \rightarrow n_i).
\]

Inserting this expression for the likelihood, and the prior site type frequencies \( f_s \) and \( f_t \) for \( P(s) \) and \( P(t) \), in the expression for the posterior probability (26.1), we thus have the following equation for the posterior probabilities of the site types:

\[
P(t|n_1, ..., n_k) = \frac{P(n_1, ..., n_k|t)f_t}{\sum_{s \in S} P(n_1, ..., n_k|s)f_s} = \frac{\prod_{i=1}^{k} \sum_{N \in \{A,C,G,T,-\}} P_t(N) \times e_q(N \rightarrow n_i)f_t}{\sum_{s \in S} \prod_{i=1}^{k} \sum_{N \in \{A,C,G,T,-\}} P_s(N) \times e_q(N \rightarrow n_i)f_s}
\]

The unknowns in this equation are the prior site type probabilities, \( f_s, s \in S \), and the error rates \( \{e(N \rightarrow M)|N, M \in \{A,C,G,T,-\}\} \). Once these have been estimated, we can calculate the posterior site type probabilities using the equation 26.3 for each site type, and hence, for each site, evaluate whether the sum of the posterior probabilities of the non-homozygous reference site types is larger than the cut-off. If so, we will set out current estimated site type to be that with the highest posterior probability.

**Estimating the parameters in the model for the Fixed Ploidy Variant Detection tool**

The Fixed Ploidy Variant Detection tool uses the Expectation Maximization (EM) procedure for estimating the unknown parameters in the model, that is, the prior site type probabilities, \( f_s, s \in S \) and the error rates \( \{e(N \rightarrow M)|N, M \in \{A,C,G,T,-\}\} \). The EM procedure is an iterative procedure: it starts with a set of initial prior site type frequencies, \( f_s^0, s \in S \) and a set of initial error probabilities, \( \{e_{0q}(N \rightarrow M)|N, M \in \{A,C,G,T,-\}\} \). It then iteratively updates first the prior site type frequencies (to get \( f_s^1, s \in S \), then the error probabilities (to get \( \{e_{1q}(N \rightarrow M)|N, M \in \{A,C,G,T,-\}\} \), then the site type frequencies again, etc. (a total of four rounds), in such a manner that the observed nucleotide patterns at the sites in the alignment become increasingly likely. To give an example of the forces at play in this iteration:
as you increase the error rates you will decrease the likelihood of observing 'clean' patterns (e.g. patterns of only As and Cs at site types A/C) and increase the likelihood of observing 'noisy' patterns (e.g. patterns of other than only As, and C at site types A/C). If, on the other hand, you decrease the error rates, you will increase the likelihood of observing 'clean' patterns and decrease the likelihood of observing 'noisy' patterns. The EM procedure ensures that the balance between these two is optimized relative to the data observed (assuming, of course, that the ploidy assumption is valid).

Updating equations for the prior site type probabilities

We first derive the updating equations for the prior site type probabilities \( f_s, s \in S \). The probability that the site is of type \( t \) given that we observe the nucleotides \( n_1, ..., n_k \) in the reads at the site is:

\[
P(t|n_1, ..., n_k) = \frac{P(t, n_1, ..., n_k)}{\sum_{s \in S} P(s, n_1, ..., n_k)} = \frac{P(t)P(n_1, ..., n_k|t)}{\sum_{s \in S} f_s P(n_1, ..., n_k|s)} \tag{26.4}
\]

Now, for \( P(t) \) we use our current value for \( f_t \), and if we further insert the expression for \( P(n_1, ..., n_k|t) \) (26.2) we get:

\[
P(t|n_1, ..., n_k) = \frac{f_t \prod_{i=1}^{k} \sum_{N \in \{A,C,G,T,-\}} P_t(N) \times e_q(N \rightarrow n_i)}{\sum_{s \in S} f_s \prod_{i=1}^{k} \sum_{N \in \{A,C,G,T,-\}} P_s(N) \times e_q(N \rightarrow n_i)} \tag{26.5}
\]

We get the updating equation for the prior site type probabilities, \( f_t, t \in S \), from equation 26.5: Let \( h \) index the sites in the alignment \( (h = 1, ..., H) \). Given the current values for the set of site frequencies, \( f_t, t \in S \), and the current values for the set of error probabilities, we obtain updated values for the site frequencies, \( f_t^*, t \in S \), by summing the site type probabilities given the data (as given by equation 26.5) across all sites in the alignment:

\[
f_t^* = \frac{\sum_{h=1}^{H} f_t \prod_{i=1}^{k} \sum_{N \in \{A,C,G,T,-\}} P_t(N) \times e_q(N \rightarrow n_i^h)}{H} \tag{26.6}
\]

Updating equations for the error rates

For the updating equations for the error probabilities, we consider a read, \( i \), at a given site, \( h \). The joint probability of the true nucleotide in the read, \( r_i^h \), at the site being \( N \) and the data \( n_1^h, ..., n_k^h \) is:
Using Bayes formula again, as we did above in 26.4, we get:

\[
P(r_i^h = N, n_i^h, \ldots, n_{k_h}^h) = \sum_{s \in S} f_s P(r_i^h = N, n_i^h, \ldots, n_{k_h}^h | s) \]

\[
= \sum_{s \in S} f_s \prod_{i} P(r_i^h = N, n_i^h | s) \]

\[
= \sum_{s \in S} f_s P(r_i^h = N, n_i^h | s) \prod_{j \neq i} P(n_j^h | s) \]

\[
= \sum_{s \in S} f_s (P_s(N) \times e_{q,h}(N \rightarrow n_i^h)) \prod_{j \neq i} \sum_{N' \in \{A,C,G,T,-\}} P_s(N') \times e_{q,j}(N' \rightarrow n_j^h) \]  

(26.7)

Using Bayes formula again, as we did above in 26.4, we get:

\[
P(r_i^h = N | n_i^h, \ldots, n_{k_h}^h) = \frac{P(r_i^h = N, n_i^h, \ldots, n_{k_h}^h)}{\sum_{s \in S} f_s P_s(N) \times e_{q,h}(N \rightarrow n_i^h) \prod_{j \neq i} \sum_{N' \in \{A,C,G,T,-\}} P_s(N') \times e_{q,j}(N' \rightarrow n_j^h)} \]

(26.8)

and inserting the expression from equation 26.7:

\[
P(r_i^h = N | n_i^h, \ldots, n_{k_h}^h) = \frac{\sum_{s \in S} f_s (P_s(N) \times e_{q,h}(N \rightarrow n_i^h)) \prod_{j \neq i} \sum_{N' \in \{A,C,G,T,-\}} P_s(N') \times e_{q,j}(N' \rightarrow n_j^h))}{(\sum_{s \in S} f_s (P_s(N) \times e_{q,h}(N \rightarrow n_i^h)) \prod_{j \neq i} \sum_{N' \in \{A,C,G,T,-\}} P_s(N') \times e_{q,j}(N' \rightarrow n_j^h))} \]

(26.9)

The equation 26.9 gives us the probabilities for a given read, \(i\), and site, \(h\), given the data \(n_i^h, \ldots, n_{k_h}^h\), that the true nucleotide is \(N, N \in \{A, C, G, T, -\}\), given our current values of the error rates and site probabilities. Since we know the sequenced nucleotide in each read at each site, we can get new updated values for the error rate of producing an \(M\) nucleotide when the true nucleotide is \(N, e_{q}(N \rightarrow M)\), for \(N, M \in \{A, C, G, T, -\}\) by summing the probabilities of the true nucleotide being \(N\) for all reads across all sites for which the sequenced nucleotide is \(M\), and dividing by the sum of all probabilities of the true nucleotide being a \(N\) across all reads and all sites:

\[
e_{q}(N \rightarrow M) = \frac{\sum_{i=1}^{\ldots} k_h \cdot r_i^h = M P(r_i^h = N | n_i^h, \ldots, n_{k_h}^h)}{\sum_{i=1}^{\ldots} k_h \cdot r_i^k = N | n_i^h, \ldots, n_{k_h}^h} \]

26.8.2 The Low Frequency Variant Detection tool: Models and methods

This section describes the model, method and estimation procedure behind the Low Frequency Variant Detection tool. The Low Frequency Variant Detection tool is designed to detect variants in a sample for which the ploidy is unknown. The Low Frequency Variant Detection tool has a particularly high sensitivity for detecting variants that are present at any, and in particularly at low, allele frequencies.

The model for the Low Frequency Variant Detection tool

The purpose of the Low Frequency Variant Detection tool is to call variants in samples with unknown ploidy (e.g., samples of limited tumor purity) using read mapping data. It will detect germline as well as somatic variants, and may also be used on samples from other high-ploidy organisms, or pooled samples. Like the Fixed Ploidy Variant Detection tool it detects Single Nucleotide Variants (SNVs), MNVs (Multiple Nucleotide Variants), insertions, deletions as well as replacements (combinations of neighboring insertions, deletions and SNVs for which the positions are ambiguous).

The Low Frequency Variant Detection algorithm relies on multinomial models to determine the presence of different alleles at a given site and an error model to account for sequencing error. The error model employed here is the same as is used in the Fixed Ploidy Variant Detection tool, described in section 26.8.1.

The multinomial models are of the kind "there are $q$ different nucleotide alleles present at the site with frequencies $f_i$, $i = 1, ..., q$, $\sum_{i=1}^{q} f_i = 1$", where the number of alleles, $q$, differ. The models that are evaluated at each site are given in Table 26.1.

Table 26.1: The multinomial models evaluated at each site. $X, Y, Z, W$ and $V$ each take on one of the values $A, C, G, T$, or $-$ ($X \neq Y \neq Z \neq W \neq V$). Free parameters*: the parameters that are free in each of the multinomial models of the Low Frequency Variant Detection tool.

In words, model $M_x$ can be described as: "There is really only the X nucleotide allele present at the site, all other nucleotides are due to errors" and model $M_{x,y,z}$ as: "There are really only the
nucleotide alleles $X$, $Y$ and $Z$ present at the site, all other nucleotides are due to errors*. The hypotheses where a single nucleotide is present in the sample have no free parameters (there is just one frequency parameter and it must be 1). A hypothesis stating that a site is a mixture of two different nucleotides, e.g. [A/G] has one free parameter since there are frequencies for two nucleotides but they have to sum to one.

Parameter estimation relies on the Maximum Likelihood principle, and, as the Fixed Ploidy Variant Detection tool, the EM algorithm is used for estimating the parameters of the model. Given an initial set of parameter values for the error rates, the different multinomial models are evaluated at each site by finding the maximum likelihood estimates of the frequency parameters for each model. The model that offers the best explanation of the data (while taking care to adjust for the numbers of parameters in the multinomial model, using a criterion adopted from the Akaike Information criterion) is chosen as the current guess of the true allelic situation at that site, and given that, the error rates are re-estimated. Given the new error estimates, the maximum log likelihoods for all possible multinomial models are again evaluated and updated frequencies are produced. This procedure is performed a total of four times. After the final round of estimation the multinomial model that offers the best explanation of the data is chosen as the winning model, and variants are called according to that model.

Below we describe in detail how we choose among competing models and derive the updating equations for the EM estimation of the frequency and error rate parameters.

**Updating the choice of favored multinomial model for each site**

Given a set of error rates, and, for each site, a set of Maximum Likelihood estimates of the nucleotide allele frequencies for each multinomial model, we can calculate the Maximum loglikelihood values for each of the models at each site. Since the hypotheses with fewer free parameters are special cases of hypotheses with more free parameters, the hypotheses with the most free parameters will necessarily have the highest likelihoods. We wish to only favor a model with more parameters over one with fewer, if it offers a significantly better explanation of the data at the site. In the simple case where we have nested models (e.g. a hypothesis, $H_0$, with no free parameters and an alternative hypothesis, $H_1$, which has one free parameter and contains $H_0$ as a special case) it is a well known result that twice the loglikelihood ratio is approximately $\chi^2$ distributed with a parameter that is equal to the difference between the number of free parameters in the hypotheses, $n$:

$$2 \log \frac{L(H_1)}{L(H_0)} \sim \chi^2(n).$$

If we write $c_n(p)$ for the inverse cumulative probability density function for a $\chi^2(n)$ distribution evaluated at $1 - p$, we get a cutoff value for when we prefer $H_1$ over $H_0$ at the significance level given by $p$.

We wish to compare all models together and some of these will not be nested. We therefore generalize this approach to apply to any set of multinomial model hypothesis $H_m, m = 1, ..., M$. For each model we calculate the value:

$$v_m = 2 \log \frac{L(H_m)}{L(H_0)} - c_{df_m}(p)$$

(26.10)
where $df_m$ is the number of free parameters in hypothesis $H_m$. We now prefer the hypothesis with the highest value of $v$ (note that when comparing a hypothesis with zero free parameters to another hypothesis, we get exactly the same results as with the log likelihood ratio approach). If this hypothesis is that only the reference allele is present at the site, no variants are called. For other models, the variants corresponding to the alleles hypothesized by the models are called.

The approach applied is an extension of the Akaike approach: In the Akaike approach you subtract twice the number of parameters, whereas in the approach that we apply, we subtract $cdf_x(p)$, whereby additional parameters are punished relative to the significance level, $p$, rather than in a fashion that is linear in the number of parameters. This means that the more parameters that are present, the more reluctant we will be to add even more.

**Updating equations for the multinomial model frequency parameters**

Consider a site, $h$, and let $n_i^h$ be the nucleotide observed in read $i$ at this site, $i = 1, ..., k$. For each of the multinomial models that may explain the data at the site we have a number of frequency parameters. For simplicity, we consider the model which states that there are two alleles present at the site, the reference allele, $y$, and another allele $x$, and let $f$ be the frequency parameter for the non-reference allele (hence the frequency of the reference allele, $f_y$, is $1 - f$). Models with more alleles are treated in a similar manner.

We want to estimate the parameter for the frequency of the $x$ allele at the site $h$, $f$, by the fraction of true nucleotides that are $x$ at this site, given the observed data:

$$f^* = \frac{\sum_{i=1}^{k} P(r_i^h = x|n_i^h)}{k}. \quad (26.11)$$

To calculate this we use Bayes Theorem on the numerator:

$$P(r_i^h = x|n_i^h) = \frac{P(r_i^h = x, n_i^h)}{P(n_i^h)} = \frac{P(x) \times e(x \rightarrow n_i^h)}{P(x) \times e(x \rightarrow n_i^h) + P(y) \times e(y \rightarrow n_i^h)} = \frac{f \times e(x \rightarrow n_i^h) + (1 - f) \times e(y \rightarrow n_i^h)}{f \times e(x \rightarrow n_i^h) + (1 - f) \times e(y \rightarrow n_i^h)}. \quad (26.12)$$

Inserting our current values for the frequency parameter $f$ under the model, and the error rates $e(x \rightarrow n_i^h)$ and $e(y \rightarrow n_i^h)$, in 26.12, and further inserting the obtained values in 26.11 gives us updated values for the frequency parameter $f$.

**Updating equations for the error rates**

Consider a site $h$ and a read $i$. The joint probability of the true nucleotide in the read, $r_i^h$, at the site being $N$ and the observed nucleotide at the site $n_i^h$ is:

$$P(r_i^h = N, n_i^h) = P_h(N)e_{q_h}(N \rightarrow n_i^h). \quad (26.15)$$
Using Bayes Theorem, the probability of the true nucleotide in the read, $r_i^h$, at the site being $N$, given that we observe $n_i^h$ is:

$$P(r_i^h = N|n_i^h) = \frac{P(r_i^h = N, n_i^h)}{\sum_{N' \in \{A,C,G,T,-\}} P(r_i^h = N', n_i^h)}.$$  \hspace{1cm} (26.16)

Inserting 26.15 in 26.16 we get:

$$P(r_i^h = N|n_i^h) = \frac{P_h(N)e_{q_i^h}(N \rightarrow n_i^h)}{\sum_{N' \in \{A,C,G,T,-\}} P_h(N')e_{q_i^h}(N' \rightarrow n_i^h)}.$$ \hspace{1cm} (26.17)

The equation 26.17 gives us the probabilities for a given read, $i$, and site, $h$, given the observed nucleotide $n_i^h$, that the true nucleotide is $N$, $N \in \{A,C,G,T,-\}$, given our current values for the frequency $f$ (inserted for $P_h(N)$) and error rates. Since we know the sequenced nucleotide in each read at each site, we can get new updated values for the error rate of producing an $M$ nucleotide when the true nucleotide is $N$, $e_{q_i^h}(N \rightarrow M)$, for $N, M \in \{A,C,G,T,-\}$ by summing the probabilities of the true nucleotide being $N$ for all reads across all sites for which the sequenced nucleotide is $M$, and dividing by the sum of all probabilities of the true nucleotide being a $N$ across all reads and all sites:

$$e_{q_i^h}(N \rightarrow M) = \frac{\sum_{h} \sum_{i=1,\ldots,k_h} P(r_i^k = N|n_i^k)}{\sum_{h} \sum_{i=1,\ldots,k_h} P(r_i^k = N|n_i^k)}$$

**Probability of the variant**

A probability value is reported for each variant call in the variant track table column with the header "Probability". For the Fixed Ploidy Variant Detection tool this value is the posterior probability of the site being different from the homozygous reference site. This is possible to calculate because the model behind the Fixed Ploidy Variant Detection tool is Bayesian. As the model for the Low Frequency Variant Detection tool is not a Bayesian model, such a value strictly speaking does not exist. However, as a proxy for such a value we report the support for the winning model $m$ relative to the total support of all models:

$$P_m = \frac{e_{q_m}}{\sum_{m'} e_{q_{m'}}}$$

**26.9 Variant data**

Variant data may be obtained either by importing variants from files (e.g. gvf or vcf files - as described in section 6.2), by downloading variants from external databases (e.g. dbSNP, HapMap, or 1000genomes - (described in section 6.2)) or by calling variants on reads tracks or read mappings using the CLC Basic Variant Detection (section 26.4), Fixed Ploidy Variant Detection (section 26.2), or the Low Frequency Variant Detection (section 26.3) tools.

Variant types include SNVs, MNVs, insertions, deletions or replacements. They may be presented either in a variant track (see figure 26.19) or in an annotated variant table (see figure 26.22).
26.9.1 Variant tracks

A variant track (figure 26.19) usually contains the following information for each variant:

Chromosome The name of the reference sequence on which the variant is located.

Region The region on the reference sequence at which the variant is located. The region may be either a 'single position', a 'region' or a 'between position region'. Examples are given in figure 26.20.

Type The type of variant. This can either be SNV (single-nucleotide variant), MNV (multi-nucleotide variant), insertion, deletion, or replacement. Learn more in section 26.9.3.

Reference The reference sequence at the position of the variant.

Allele The allele sequence of the variant.

Reference allele Describes whether the variant is identical to the reference. This will be the case one of the alleles for most, but not all, detected heterozygous variants (e.g. the variant
detection tool might detect two variants, A and G, at a given position in which the reference is ‘A’. In this case the variant corresponding to allele ‘A’ will have ‘Yes’ in the ‘reference allele’ column entry, and the variant corresponding to allele ‘G’ would have ‘No’. Had the variant detection tool called the two variants ‘C’ and ‘G’ at the position, both would have had ‘No’ in the ‘Reference allele’ column).

Length The length of the variant. The length is 1 for SNVs, and for MNVs it is the number of allele or reference bases (which will always be the same). For deletions, it is the length of the deleted sequence, and for insertions it is the length of the inserted sequence. For replacements, both the length of the replaced reference sequence and the length of the inserted sequence are considered, and the longest of those two is reported.

Linkage

Zygosity The zygosity of the variant called, as determined by the variant detection tool. This will be either ‘Homozygous’, where there is only one variant called at that position or ‘Heterozygous’ where more than one variant was called at that position.

Count The number of ‘countable’ reads supporting the allele. The ‘countable’ reads are those that are used by the variant detection tool when calling the variant. Which reads are ‘countable’ depends on the user settings when the variant calling is performed - if e.g. the user has chosen ‘Ignore broken pairs’, reads belonging to broken pairs are not ‘countable’. Note that, although overlapping paired reads have two reads in their overlap region, they only represent one fragment, and are counted only as one. (Please see the column ‘Read count’ below for a column that reports the value for ‘reads’ rather than for ‘fragments’). Note also that the count value reported in the table may differ from the one accessible from the track’s tooltip, as the ‘count’ value in the table is generated taking into account quality score and frequency of sequencing errors.

Coverage The fragment coverage at this position. Only ‘countable’ fragments are considered (see under ‘Count’ above for an explanation of ‘countable’ fragments). Note that, although overlapping paired reads have two reads in their overlap region, they only represent one fragment, and overlapping paired reads contribute only 1 to the coverage. (Please see the column ‘Read coverage’ below for a column that reports the value for ‘reads’ rather than for ‘fragments’).
for 'fragments'). Also see overlapping pairs in section 26.1.3 for how overlapping paired reads are treated.)

**Frequency**  The number of 'countable' reads supporting the allele divided by the number of 'countable' reads covering the position of the variant ('see under 'Count' above for an explanation of 'countable' reads). Please see section 27.2.3 for a description of how to remove low frequency variants.

**Probability**  The probability that this particular variant exists in the sample. (For further information please refer to the White paper on Probabilistic Variant Detection tool: http://resources.qiagenbioinformatics.com//white-papers/White_paper_on_probabilistic_variant_caller_1.1.pdf).

**Forward and Reverse read count**  The number of 'countable' forward or reverse reads supporting the allele (see under 'Count' above for an explanation of 'countable' reads). Also see more information about overlapping pairs in section 26.1.3.

**Forward and Reverse read coverage**  Coverage for forward or reverse reads supporting the allele.

**Forward/reverse balance**  The minimum of the fraction of 'countable' forward reads and 'countable' reverse reads carrying the variant among all 'countable' reads carrying the variant (see under 'Count' above for an explanation of 'countable' reads). Some systematic sequencing errors can be triggered by a certain combination of bases. This means that sequencing one strand may lead to sequencing errors that are not seen when sequencing the other strand. In order to evaluate whether the distribution of forward and reverse reads is approximately random, this value is calculated as the minimum of the number of forward reads divided by the total number of reads and the number of reverse reads divided by the total number of reads supporting the variant. An equal distribution of forward and reverse reads for a given allele would give a value of 0.5. (See also more information about overlapping pairs in section 26.1.3.)

**Average quality**  The average base quality score of the bases supporting a variant. In the case of a deletion, the quality score is taken from the average quality of the two bases neighboring the deleted one, and the lowest is reported. Similarly for insertions, the quality in reads where the insertion is absent is taken from the minimum average of the two bases on either side of the position. It can be possible in rare cases, that the quality score reported in this column for a deletion or insertion is below the threshold set for 'Minimum central quality', because this parameter is not applied to any quality value calculated from positions outside of the central variant. To remove low quality variants from the output, use the **Remove Marginal Variants** tool (see section 27.2.3).

If there are no values in this column, it is probably because the sequencing data was imported without quality scores (learn more about importing quality scores from different sequencing platforms in section 6.3).

Please note that the variants in the variant track can be enriched with information using the annotation tools in section 27.3.

A variant track can be imported and exported in VCF or GVF formats. An example of the gvf-file giving rise to the variants shown in figure 26.20 is given in figure 26.21.
26.9.2 The annotated variant table

While the track table contains reference alleles and non-reference alleles, the annotated table lists only non-reference alleles. It include for each allele a subset of the columns of the variant track table and three additional columns (see figure 26.22).

</tbody>
</table>

**Overlapping annotation** This shows if the variant is covered by an annotation. The annotation’s type and name will be displayed. For annotated reference sequences, this information can be used to tell if the variant is found in a coding or non-coding region of the genome. **Note** that annotations of type Variation and Source are not reported.

**Coding region change** For variants that fall within a coding region of a gene, the change is reported according to the standard conventions as outlined in [http://varnomen.hgvs.org/](http://varnomen.hgvs.org/).

**Amino acid change** If the reference sequence of the mapping is annotated with ORF or CDS annotations, the variant detection tool will also report whether the variant is synonymous or non-synonymous. If the variant changes the amino acid in the protein translation, the new amino acid will be reported. The nomenclature used for reporting is taken from [http://varnomen.hgvs.org/](http://varnomen.hgvs.org/).

If the reference sequence has no gene and cds annotations these columns will have the entry "NA".

Try using a stand-alone reference with a stand-alone read mapping to avoid this situation. Also, the variant track may be enriched with information similar to that contained in the above three annotated variant table columns by using the track-based annotation tools in section 27.3.

The table can be Exported as a csv file (comma-separated values) and imported into e.g. Excel. Note that the CSV export includes all the information in the table, regardless of filtering and what has been chosen in the Side Panel. If you only want to use a subset of the information, simply select and Copy the information.
Note that if you make a split view of the table and the mapping (see section 2.1.6), you will be able to browse through the variants by clicking in the table. This will cause the view to jump to the position of the variant.

This table view is not well-suited for downstream analysis, in which case we recommend working with tracks instead (see section 26.9.1).

### 26.9.3 Variant types

Variants are classified into five different types:

**SNV** A single nucleotide variant. This means that one base is replaced by one other base. This is also often referred to as a SNP. SNV is preferred over SNP because the latter includes an extra layer of interpretation about variants in a population. This means that an SNV could potentially be a SNP but this cannot be determined at the point where the variant is detected in a single sample.

**MNV** This type represents two or more SNVs in succession.

**Insertion** This refers to the event where one or more bases are inserted in the experimental data compared to the reference.

**Deletion** This refers to the event where one or more bases are deleted from the experimental data compared to the reference.

**Replacement** This is a more complex event where one or more bases have been replaced by one or more bases, where the identified allele has a length different from the reference (i.e. involving an insertion or deletion). Basically, this type represents variants that cannot be represented in the other four categories. An example could be AAA→CC. This cannot be resolved into a SNV or an MNV because the number of bases is different between the experimental data and the reference, it is not an insertion because something is also deleted from the reference, and it is not a deletion because something is also inserted.

Note about overlapping variants: If two different types of variants occur in the same location, these are reported separately in the output table. This is particularly important when SNPs occur in the same position as an MNV. Usually, multiple SNVs occurring alongside each other would simply be reported as one MNV, but if one SNV of the MNV is found in additional case samples by itself, it will be reported separately. For example, if an MNV of AAT→GCA at position 1 occurs in five of the case samples, and the SNV at position 1 of A→G occurs in an additional 3 samples (so 8 samples in total), the output table will list the MNV and SNV information separately. However, the SNV will be shown as being present in only 3 samples, as this is the number in which it appears "alone".

### 26.10 Copy Number Variant Detection

The Copy Number Variant Detection tool is designed to detect copy number variations (CNVs) from targeted resequencing experiments.

The tool takes read mappings and target regions as input, and produces amplification and deletion annotations. The annotations are generated by a 'depth-of-coverage' method, where
CHAPTER 26. VARIANT DETECTION

the target-level coverages of the case and the controls are compared in a statistical framework using a model based on 'selected' targets. Note that to be 'selected', a target has to have a coverage higher than the specified coverage cutoff AND must be found on a chromosome that was not identified as a coverage outlier in the chromosomal analysis step. If fewer than 50 'selected' targets are found suitable for setting up the statistical models, the CNV tool will terminate prematurely.

The algorithm implemented in the Copy Number Variant Detection tool is inspired by the following papers:

- **Li et al.**, CONTRA: copy number analysis for targeted resequencing, Bioinformatics. 2012, 28(10):1307-1313 [Li et al., 2012].

For more information, you can also read our whitepaper: https://www.qiagenbioinformatics.com/files/whitepapers/Biomedical_Genomics_Workbench_CNV_White_Paper.pdf.

The Copy Number Variant Detection tool identifies CNVs regions where the normalized coverage is statistically significantly different from the controls.

The algorithm carries out the analysis in several steps.

1. Base-level coverages are analyzed for all samples, and a robust coverage baseline is generated using the control samples.

2. Chromosome-level coverage analysis is carried out on the case sample, and any chromosomes with unexpectedly high or low coverages are identified.

3. Sample coverages are normalized, and a global, target-level statistical model is set up for the variation in fold-change as a function of coverage in the baseline.

4. Each chromosome is segmented into regions of similar fold-changes.

5. The expected fold-change variation in region is determined using the statistical model for target-level coverages. Region-level CNVs are identified as the regions with fold-changes significantly different from 1.0.

6. If chosen in the parameter steps, gene-level CNV calls are also produced.

26.10.1 The Copy Number Variant Detection tool

To start the Copy Number Variant Detection tool, click:

    Toolbox | Resequencing Analysis | Copy Number Variant Detection

Select the case read mapping and click Next.

You are now presented with choices regarding the data to use in the CNV prediction method, as shown in figure 26.23.
Target regions track An annotation track containing the regions targeted in the experiment must be chosen. This track must not contain overlapping regions, or regions made up of several intervals, because the algorithm is designed to operate on simple genomic regions.

Control mappings You must specify one or more read mappings, which will be used to create a baseline by the algorithm. For the best results, the controls should be matched with respect to the most important experimental parameters, such as gender and technology. If using non-matched controls, the CNVs reported by the algorithm may be less accurate.

Gene track Optional: If you wish, you can provide a gene track, which will be used to produce gene-level output as well as CNV-level output.

Ignore non-specific matches If checked, the algorithm will ignore any non-specifically mapped reads when counting the coverage in the targeted positions. Note: If you are interested in predicting CNVs in repetitive regions, this box should be unchecked.

Ignore broken pairs If checked, the algorithm will ignore any broken paired reads when counting the coverage in the targeted positions.

Threshold for significance P-values lower than the threshold for significance will be considered "significant". The higher you set this value, the more CNVs will be predicted.
**Minimum fold change, absolute value** You must specify the minimum fold change for a CNV call. If the absolute value of the fold change of a CNV is less than the value specified in this parameter, then the CNV will be filtered from the results, even if it is otherwise statistically significant. For example, if a minimum fold-change of 1.5 is chosen, then the adjusted coverage of the CNV in the case sample must be either 1.5 times higher or 1.5 times lower than the coverage in the baseline, for it to pass the filtering step. If you do not want to filter on the fold-change, enter 0.0 in this field. Also, if your sample purity is less than 100%, it is necessary to take that into account when you adjust the fold-change cutoff. This is described in more detail in section 26.10.1. Note: this value is used to filter the Region-level CNV track. The Target-level CNV track will always include full information for all targets.

**Low coverage cutoff** If the average coverage of a target is below this value, it will be considered "low coverage" and it will not be used to set up the statistical models, and p-values will not be calculated for it in the target-level CNV prediction.

**Graining level** The graining level is used for the region-level CNV prediction. Coarser graining levels produce longer CNV calls and less noise, and the algorithm will run faster. However, smaller CNVs consisting of only a few targets may be missed at a coarser graining level.

- **Coarse**: prefers CNVs consisting of many targets. The algorithm is most sensitive to CNVs spanning over 10 targets. This is the recommended setting if you expect large-scale deletions or insertions, and want a minimal false positive rate.
- **Intermediate**: prefers CNVs consisting of an intermediate number of targets. The algorithm is most sensitive to CNVs spanning 5 or more targets. This is the recommended setting if you expect CNVs of intermediate size.
- **Fine**: prefers CNVs consisting of fewer targets. The algorithm is most sensitive to CNVs spanning 3 or more targets. This is the recommended setting if you want to detect CNVs that span just a few targets, but the false positive rate may be increased.

**Note:** The CNV sizes listed above are meant as general guidelines, and are not to be interpreted as hard rules. Finer graining levels will produce larger CNVs when the signals for this are sufficiently clear in the data. Similarly, the coarser graining levels will also be able to predict shorter CNVs under some circumstances, although with a lower sensitivity.

**Enhance single-target sensitivity** All of the graining levels assume that a CNV spans more than one target. If you are also interested in very small CNVs that affect down to a single target in your data, check the ‘Enhance single-target sensitivity’ box. This will increase the sensitivity of detection of very small CNVs, and has the greatest effect in the case of the coarser graining levels. Note however that these small CNV calls are much more likely to be false positives. If this box is unchecked, only larger CNVs supported by several targets will be reported, and the false positive rate will be lower.

Clicking **Next**, you are presented with options about the results (see figure 26.25). In this step, you can choose to create an algorithm report by checking the **Create algorithm report** box. Furthermore, you can choose to output results for every target in your input, by checking the **Create target-level CNV track** box.

When finished with the settings, click **Next** to start the algorithm.
How to set the fold-change cutoff when the sample purity is not 100%

Given a sample purity of \( X \% \), and a desired detection level (absolute value of fold-change in 100% pure sample) of \( T \), the following formula gives the required fold-change cutoff:

\[
\text{cutoff} = \frac{X\%}{100\%} \times T + (1 - \frac{X\%}{100\%})
\]  

(26.18)

For example, if the sample purity is 40%, and you want to detect 6-fold amplifications or deletions (e.g. 12 copies instead of 2, or 2 copies instead of 12), then the cutoff should be:

\[
\text{cutoff} = \frac{40\%}{100\%} \times 6 + (1 - \frac{40\%}{100\%}) = 3.0.
\]  

(26.19)

Figure 26.26 shows the required fold-change cutoffs in order to detect a particular degree of amplification/deletion at different sample purities. Figure 26.27 zooms in for low-level amplifications and deletions.

The Copy Number Variant Detection tool calls CNVs that are both global outliers on the target-level, and locally consistent on the region-level. The tool produces several outputs, which are described below.

### 26.10.2 Region-level CNV track (Region CNVs)

The algorithm will produce a region-level annotation track, which contains the CNV regions detected by the algorithm. Every annotation in this track joins one more more targets from the input target track, to produce contiguous CNVs. Each CNV in the region-level tracks is characterized in terms of the following properties:

**Minimum CNV length:** The minimum CNV length is the length of the region-level CNV annotation. This number should be interpreted as the lowest bound for the size of the CNV. The "true" CNV can extend into the adjacent genomic regions that have not be targeted.

**P-value:** The p-value corresponds to the probability that an observation identical to the CNV, or even more of an outlier, would occur by chance under the null hypothesis. The null hypothesis is that of no CNVs in the data. The p-value for a CNV region is calculated by combining the p-values of its constituent targets (discarding any low-coverage targets).
Fold-change (adjusted): The fold-change of the adjusted case coverage compared to the baseline. Negative fold-changes indicate deletions, and positive fold-changes indicate amplifications. A fold-change of 1.0 (or -1.0) represents identical coverages. The fold-changes are adjusted for statistical differences between targets with different sequencing depths. Note: if your sample purity is less than 100%, you need to take that into account when interpreting the fold-change values. This is described in more detail in section 26.10.2.
Consequence: The consequence classifies statistically significant CNVs as "Gain" or "Loss".

Number of targets: The total number of targets forming the (minimal) CNV region.

Targets: A list of the names of the targets forming the (minimal) CNV region. Note however that the list is truncated to 100 characters. If you want to see all the targets that constitute the CNV region, you can use the target-level output (section 26.10.3).

Comments: The comments can include useful information for interpreting individual CNV calls. The possible comments are:

1. Small region: If a region only consists of 1 target, it is classified as a 'small region'. The p-value of this region is therefore based on evidence from just one target, and may be less accurate than p-values for larger regions.
2. Disproportionate chromosome coverage: If a region is found on a chromosome that was determined to have disproportionate coverage, this will be noted in the comments. This means that the targets constituting this region were not used to set up the statistical models. Furthermore, the size and fold-change value of this CNV region may explain why the chromosome was detected to have disproportionate coverage.
3. Low coverage: If all targets inside a region had low-coverage, then the region will be classified as a 'low-coverage' region, and will be given a p-value of 1.0. You will only see these regions in the results if you set the significance cutoff to 1.0.

These properties can be found in separate columns when viewing the tracks in table view.

Note: The region-level calls do not guarantee that a single, larger CNV will always be called in just one CNV region. This is because adjacent region-level CNV calls are not joined into a single region if their average fold-changes are sufficiently different. For example, if a 2-fold gain is detected in a region and a 3-fold gain is detected in an immediately adjacent region of equal size, then these may appear in the results as two separate CNVs, or one single CNV with a 2.5-fold gain, depending on your chosen graining level, and the fold-changes observed in the rest of the data.

How to interpret fold-changes when the sample purity is not 100%

If your sample purity is less than 100%, it is necessary to take that into account when interpreting the fold-change values. Given a sample purity of $X\%$, and an observed fold-change of $F$, following formula gives the actual fold-change that would be seen if the sample were 100% pure:

$$\text{fold-change in 100% pure sample} = \frac{F - 1}{X/100\%} + 1$$  \hspace{1cm} (26.20)

For example, if the sample purity is 40%, and you have observed a fold-change of 3, then the fold-change in the 100% pure sample would have been:

$$\text{fold-change in 100% pure sample} = \frac{3.0 - 1}{40\%/100\%} + 1 = 6.0.$$  \hspace{1cm} (26.21)

Figures 26.28 shows the ‘true’ fold changes for different observed fold-changes at different sample purities. Figure 26.29 zooms in for low-level amplifications and deletions.
26.10.3 Target-level CNV track (Target CNVs)

The algorithm will produce a target-level CNV track, if you’ve chosen to create one when running the algorithm. The target-level CNV track is an annotation track, containing one annotation for every target in the input data. Inspection of the target-level CNV track can give you additional information about both the CNVs called in the region-level results, and those regions that have not been called. Note that a "statistically relevant" target is one that has a coverage higher...
than the specified coverage cutoff, AND is found on a a chromosome that was not identified as a coverage outlier in the chromosomal analysis step. The sample is not considered covered enough for statistical purposes if you have fewer than 49 targets that can be used to do the statistics.

Each target is annotated with the following information:

**Target number:** Targets are numbered in the order in which they occur in the genome. This information is used by the results report (see section 26.10.5).

**Case coverage:** The normalized coverage of the target in the case sample.

**Baseline coverage:** The normalized coverage of the target in the baseline.

**Length:** The length of the target region.

**P-value:** The p-value corresponds to the probability that an observation identical to the CNV, or even more of an outlier, would occur by chance under the null hypothesis. The null hypothesis is that of no CNVs in the data. The p-value in the target-level output reflects the global evidence for a CNV at that particular target. The target-level p-values are combined to produce the region-level p-values in the region-level CNV output.

**FDR-corrected p-value:** The FDR-corrected p-values correct for false positives arising from carrying out a very high number of statistical tests. The FDR-corrected p-value will, therefore, always be larger than the uncorrected p-value.

**Fold-change (raw):** The fold-change of the normalized case coverage compared to the normalized baseline coverage. The normalization corrects for the effects of different library sizes between the different samples. Negative fold-changes indicate deletions, and positive fold-changes indicate amplifications. A fold-change of 1.0 represents identical coverages.

**Fold-change (adjusted):** As observed by Li et al (2012, [Li et al., 2012]), the fold-changes (raw) depend on the coverage. Therefore, the fold-changes have to be adjusted for statistical differences between targets with different sequencing depths, before the statistical tests are carried out. The results of this adjustment are found in the "Fold-change (adjusted)" column. Note that sometimes, this will mean that a change that appears to be an amplification in the "raw" fold-change column may appear to be a deletion in the "adjusted" fold-change column, or vice versa. This is simply because for a given coverage level, the raw fold-changes were skewed towards amplifications (or deletions), and this effect was corrected in the adjustment. Note: if your sample purity is less than 100%, you need to take that into account when interpreting the fold-change values. This is described in more detail in section 26.10.2.

**Region (joined targets):** The region to which this target was classified to belong. The region may or may not have been predicted to be a CNV.

**Regional fold-change:** The adjusted fold-change of the region to which this target belongs. This fold-change value is computed from all targets constituting the region.

**Regional p-value:** The p-value of the region to which this target belongs. This is the p-value calculated from combining the p-values of the individual targets inside the region.
Regional consequence: If the target is included in a CNV region, this column will show "Gain" or "Loss", depending on the direction of change detected for the region. Note, however, that the change detected for the region may be inconsistent with the fold-change for a single target in the region. The reason for this is typically statistical noise at the single target. Regional consequence column is only filled in the target-level output when the region is both significant (determined by the p-value) AND has a "Strong" effect size (determined by the fold-change).

Regional effect size: The effect size of a target-level CNV reflects the magnitude of the observed fold-change of the CNV region in which the target was found. The effect size of a CNV is classified into the following categories: "Strong" or "Weak". The effect size is "Strong" if the fold-change exceeds the fold-change cutoff specified in the parameter steps. A "Weak" CNV calls will be filtered from the region-level output. Regional effect size column is only filled in the target-level output when the region is both significant (determined by the p-value) AND has a "Strong" effect size (determined by the fold-change).

Comments: The comments can include useful information for interpreting the CNV calls. Possible comments in the target-level output are:

1. Low coverage target: If the target had a coverage under the specified coverage cutoff, it will be classified as low-coverage. Low-coverage targets were not used in calculating the statistical models, and will not have p-values.
2. Disproportionate chromosome coverage: If the target occurred on a chromosome that was detected to have disproportionate coverage. In this case, the target was not used to set up the statistical models.
3. Atypical fold-change in region: If there is a discrepancy between the direction of fold-change detected for the target and the direction of fold-change detected for the region, then the fold-change of the target is "atypical" compared to the region. This is usually due to statistical noise, and the regional fold-change is likely to be more accurate in the interpretation, especially for large regions.

26.10.4 Gene-level annotation track (Gene CNVs)
If you have specified a gene track in the input parameters, you will get a gene-level CNV track as well. The gene-level CNV track is an annotation track, which is obtained by intersecting the region-level CNV track with the gene track in the input (ignoring any genes that do not overlap with the targets). Note that a single CNV may be reported several times in different genes, and a single gene may also be reported several times, if it is affected by more than one CNV. In addition to the annotations on the gene track supplied in the input parameters, the gene-level CNV track contains the following annotation columns:

Region length: The length of the actual annotation. That is, the length of the CNV region intersected with the gene.

CNV region: The entire CNV region affecting this gene (and possibly other genes).

CNV region length: The length of the entire CNV region affecting this gene (and possibly other genes).

Consequence: The consequence classifies statistically significant CNVs as "Gain" or "Loss".
**Fold-change (adjusted):** The adjusted fold-change of the entire CNV region affecting this gene (and possibly other genes).

**P-value:** The p-value of the entire CNV region affecting this gene (and possibly other genes).

**Number of targets:** The total number of targets forming the entire CNV region affecting this gene (and possibly other genes).

**Comments:** If the CNV region affecting this gene had any comments (as described in section 26.10.2), this will be present in the gene-level results as well.

**Targets:** A list of the names of the targets forming the (minimal) CNV region forming the entire CNV region affecting this gene (and possibly other genes). Note however that the list is truncated to 100 characters. If you want to know the full list of targets inside the CNV region, you can use the target-level output track.

### 26.10.5 CNV results report

The report contains information about the results of the Copy Number Variant Detection tool.

**Normalization** The Normalization section gives information about the sample-level and chromosome-level coverages. Any chromosomes with disproportionate coverages are noted; targets on these chromosomes were ignored when setting up the statistical models.

**Target-level log2-ratios** The target-level coverage log-ratios are presented as a graph. An example is shown in figure 26.30. On the horizontal axis, the targets are placed in the order in which they appear in the genome. On the vertical axis, the adjusted coverage log-ratio of each target is plotted. The black line represents the actually observed mean adjusted log-ratio of coverage for each target. The cyan and red lines represent the 95% confidence intervals of the expected mean adjusted log-ratios of coverages, based on the statistical model. Chromosome boundaries are indicated as vertical lines.

**CNV statistics** The last section in the report provides some information about the number of CNVs called in the region-level prediction results. The number of uncalled or filtered regions are also shown.

### 26.10.6 CNV algorithm report

If you have chosen to produce an algorithm report in the output handling step of the wizard, an algorithm report will also be produced. This contains information about the statistical models of the algorithm, and can be used to evaluate how well the assumptions of the model were fulfilled. We will now present the different sections of this report.

**Normalization and chromosome analysis**

This section of the report is related to the first step of the Copy Number Variant Detection tool, where the chromosome-level coverages are analyzed to detect any outliers. The total coverages of the case chromosomes are plotted against the total coverages of the baseline, and the detected outliers are indicated. Chromosome coverages identified as disproportionate are marked with red crosses (see figure 26.31).
Figure 26.30: An example graph showing the mean adjusted log-ratios of coverages in the report produced by the Copy Number Variant Detection tool. In this example, the second and ninth chromosomes are amplified, and the log-ratios of coverages of targets on these chromosome are significantly higher than for targets on other chromosomes. The black line in these regions is outside the boundaries defined by the cyan and red lines.

Figure 26.31: An example graph showing the coverages of the chromosomes in the case versus the baseline. In this example, three chromosomes are marked as abnormal. Two of these chromosomes are significantly amplified, and log-ratios of coverages of many targets on these chromosome are significantly higher than for targets on other chromosomes. The third outlier chromosome had zero coverage in both the case and the baseline.

The graph is followed by a table, where the detailed chromosome coverages are shown after normalization. Chromosomes with disproportionate coverage and chromosomes without any targets are marked in the 'Comment' column. These chromosomes are the ones marked with red crosses in the graph in section 1.1. of the algorithm report, and these chromosomes were not used in the coverage normalization step.
Prediction of target-level CNVs

This section of the algorithm report gives information about the statistical models used to predict target-level CNVs.

Adjustment of log2-ratios The first two graphs in this section are related to the adjustment of the log-ratios of coverages as a function of log-coverage. The log-ratio of coverages for targets depends on the level of coverage of the target, as observed by Li et al. (Bioinformatics, 2012), who also proposed that a linear correction should be applied [Li et al., 2012]. In the first of the two graphs, the non-adjusted log-ratios of target coverages are plotted against the log-coverage of the targets. In the second graph, the mean log-ratios are plotted after adjustment (figure 26.32). If the model fits the data, we expect to see that the adjusted mean log-ratios are centered around 0 for all log-coverages, and the variation decreases with increasing log-coverage.

Figure 26.32: An example graph showing the mean adjusted log-ratios of coverages plotted against the log-coverages of targets, in the algorithm report of the Copy Number Variation Detection tool. Here, the adjusted mean log-ratios are centered around 0.0 for most coverages, and the variation decreases with increasing log-coverage. This indicates a good fit of the model. However, at very high coverages, the adjusted log-ratios are centered higher than 0.0, which indicates that for these coverages, the model is not a perfect fit. But only very few targets are affected by this, as the points are very sparse at these high coverage levels.

Statistical model for adjusted log2-ratios In this section of the algorithm report, you can see how well the algorithm was able to model the statistical variation in the log-ratios of coverages. An example is shown in figure 26.33). A good fit of the model to the data points indicates that the variance has been modeled accurately.

To make the points more visible, double-click the figure, to open it in a separate editor. Here, you can select how to visualize the data points and the fitted model. For example, you can choose to highlight the data points in the sidepanel:

MA Plot Settings | Dot properties | Dot type | "Dot"

Distribution of adjusted log2-ratios in bins One of the assumptions of the statistical model used by the CNV detection tool is that the coverage log-ratios of targets are normally distributed with a
mean of zero, and the variance only depends on the log-coverage of each target in the baseline. The bar charts in this section of the algorithm report show how well this assumption of the model fits the data. An example is shown in figure 26.34). A good fit of the model to the data points indicates that the variance has been modeled accurately.

Prediction of region-level CNVs

The final section of the algorithm report is related to the region-level CNV prediction. In this part of the algorithm, the chromosomes are segmented into regions of similar adjusted mean log-ratios. More segments lead to a reduced variance per segment; in the extreme, where every target forms its own segment, the variance is zero. However, more segments also mean that the model contains more free parameters, and is therefore potentially over-fitted. A value known as the Bayesian Information Criterion (BIC) gives an indication of the balance of these two effects,
for any potential segmentation of a chromosome. The segmentation process aims to minimize the BIC, producing the best balance of accuracy and overfitting in the final segments.

The segmentation begins by identifying a set of potential breakpoints, known as local maximizers. The number of potential breakpoints at the start of the segmentation is shown in the "# local maximizers at start" column, and the corresponding BIC score is indicated in the "Start BIC" column. Breakpoints are removed strategically one-by-one, and the BIC score is calculated after each removal. When enough breakpoints have been removed for the BIC score to reach its minimum, the final number of breakpoints is shown in the "# local maximizers at end" column, and the corresponding BIC score is indicated in the "End BIC" column. A large reduction in the number of local maximizers indicates that it was possible to join many smaller CNV regions into larger ones.

Note: The segmentation process only produces regions of similar adjusted coverage log-ratios. Each segment is tested afterwards, to identify if it represents a CNV. Therefore, the number of segments shown in this table does not correspond to the number of CNVs actually predicted by the algorithm.

### 26.11 Identify Known Mutations from Sample Mappings

The Identify Known Mutations from Sample Mappings tool can be used to look up known genomic variants in read mappings. This can be done in one or more samples by comparing a track of known variants with the read mappings of interest in order to test for the presence or absence of relevant variants in samples for example.

The Identify Known Mutations from Sample Mappings tool does not perform any kind of variant calling, which means that this tool cannot be used to find de novo variants. Rather, the tool is intended for identification of variants that have already been reported.

You need two types of input for the Identify Known Mutations from Sample Mappings tool:

- A variant track that holds the specific variants that you wish to test for.
- The read mapping(s) that you wish to check for the presence (or absence) of specific variants.

The Identify Known Mutations from Sample Mappings tool has two kinds of outputs:

- An overview track with information about:
  - whether the variant could be detected or not
  - whether the coverage was sufficient at the given position
  - the frequency of the variant in each sample.
- Individual output tracks for each sample that show the observed frequency, average base quality, forward/reverse read balance, zygosity and observed allele count.

#### 26.11.1 Run the Identify Known Mutations from Sample Mappings tool

To run the "Identify Known Mutations from Sample Mappings" tool go to the toolbox:
Toolbox | Resequencing Analysis (Identify Known Mutations from Sample Mappings)

This opens the wizard shown where you can specify the read mapping(s) to analyze. Click Next to get the following options (figure 26.35):

![Wizard for identifying known mutations from sample mappings](image)

Figure 26.35: Select the variant track with the variants that you wish to use for variant testing.

**Variant track**

- **Variant track** Select the variant track that contains the specific variants that you wish to test for in your read mapping. **Note!** You can only select one variant track at the time. If you wish to compare with more than one variant track, you must run the analysis with each individual variant track at the time.

**Detection requirements**

- **Minimum coverage** The minimum number of reads that covers the position of the variant, which is required to set "Sufficient Coverage" to YES.

- **Detection frequency** The minimum allele frequency that is required to annotate a variant as being present in the sample. The same threshold will also be used to determine if a variant is homozygous or heterozygous. In case the most frequent alternative allele at the position of the considered variant has a frequency of less than this value, the zygosity of the considered variant will be reported as being homozygous.

**Filtering**

- **Ignore broken pairs** When ticked, reads from broken pairs are ignored. Broken pairs may arise for a number of reasons, one being erroneous mapping of the reads. In general, variants based on broken pair reads are likely to be less reliable, so ignoring them may reduce the number of spurious variants called. However, broken pairs may also arise for biological reasons (e.g., due to structural variants) and if they are ignored some true variants may go undetected.
• **Ignore non-specific matches** Reads that have an equally good match elsewhere on the reference genome (these reads are colored yellow in the mapping view) can be ignored in the analysis. Whether you include these reads or not will be a tradeoff between sensitivity and specificity. Including them may lead to the prediction of transcripts that are not correct, whereas excluding them may mean that you will lose some true transcripts.

• **Include partially covering reads** Reads that partially overlap variants (see the blue box below for a definition) will be considered to enable the detection of variants that are longer than the reads. When the “Include partially covering reads” option is disabled, only fully covering reads will be counted for all annotations. Enabling the “Include partially covering reads” option means that all fully covering reads will be counted for all annotations, and that additionally, partially covering reads will be included in relevant annotations including Coverage. Thus, if a partial read is compatible with multiple variants in the same region, the sum of all Counts for that region may be greater than the Coverage, and the sum of all Frequencies for that region may be higher than 100%.

A fully covering read is described as such:

• for SNV, MNV and Deletion: the read must cover all reference positions in the variant region.

• for Insertion and Replacement: the read must overlap adjacent reference positions on both sides of the variant region.

A partially covering read is read that is not fully covering the variant region, but overlaps with at least one residue.

Click on the button labeled **Next** to go to the next wizard step (figure 26.36). At this step the output options can be adjusted.

![Identify Known Mutations from Sample Mappings](image)

**Figure 26.36:** Select the desired output format(s). If using the default settings, two types of output will be generated; individual tracks and overview tracks.

The output options are:
• **Create individual track** For each read mapping an individual track is created with the observed frequency, average base quality, forward/reverse read balance, zygosity and observed allele count.

• **Create overview track** The overview track is a summary for all samples with information about whether the coverage is sufficient at a given variant position and if the variant has been detected; the frequency of the variant.

Specify where to save the results and click on the button labeled **Finish**.

### 26.11.2 Output from the Identify Known Mutations from Sample Mappings tool

One individual sample output track will be created for each read mapping analyzed, while one overview track will be created per analysis (figure 26.37).

![Overview track of read mappings tested against a Clinvar variant track.](image)

**Figure 26.37: Overview track of read mappings tested against a Clinvar variant track.**

At the bottom of the window it is possible to switch to a table view that lists all the mutations from the variant track that were found in your sample mapping.

In the individual track, the variant has been annotated with most classical variant track annotations (see section 26.9.1), as well as:

- **Most frequent alternative allele (MFAA)**

  - **MFAA count** The Most Frequent Alternative Allele count (MFAA count) is the count of reads supporting the most frequent alternative allele at the position of the variant

  - **MFAA frequency** Frequency of reads supporting the most frequent alternative allele at the position of the variant

  - **MFAA forward read count** forward reads supporting the most frequent alternative allele at the position of the variant

  - **MFAA reverse read count** reverse reads supporting the most frequent alternative allele at the position of the variant

  - **MFAA forward/reverse balance** forward/reverse balance of the most frequent alternative allele at the position of the variant

  - **MFAA average quality** average quality of the most frequent alternative allele at the position of the variant
In the overview track the variant has been annotated with the following information:

- (**Sample name**) coverage Either Yes or No, depending on whether the coverage at the position of the variant was higher or lower than the user given threshold for minimum coverage.

- (**Sample name**) detection Either Yes or No, depending on the minimum frequency settings chosen by the user.

- (**Sample name**) frequency The variant frequency observed in this sample.

- (**Sample name**) zygosity The zygosity observed in the sample. This setting is based on the minimum frequency setting made by the user. If this variant has been detected and the most frequent alternative allele at this position is also over the cutoff, the value is heterozygote.

An example of the individual and overview tables can be seen in figure 26.38.

![Figure 26.38: Table views of the individual track (left) and overview track (right).](image)

### 26.12 InDels and Structural Variants

The InDels and Structural Variants tool is designed to identify structural variants such as insertions, deletions, inversions, translocations and tandem duplications in read mappings. The tool relies exclusively on information derived from unaligned ends (also called ‘soft clippings’) of the reads in the mappings. This means that:

- The tool will detect NO structural variants if there are NO reads with unaligned ends in the read mapping.

- Read mappings made with the CLC ‘Map reads to reference’ tool with the ‘global’ option switched on will have NO unaligned ends and the InDels and Structural Variants tool will thus find NO structural variants on these. (The ‘global’ option means that reads are aligned in their entirety - irrespectively of whether that introduces mismatches towards the ends of the reads. In the ‘local’ option such reads will be mapped with unaligned ends).

- Read mappings based on really short reads (say, below 35 bp) are not likely to produce many reads with unaligned ends of any useful length, and the tool is thus not likely to produce many structural variant predictions for these read mappings.
Read mappings generated with the Large Gap Read Mapper are NOT optimal for the detection of structural variants with this tool. This is due to the fact that, the Large Gap Read Mapper will map some reads with (large) gaps, that would be mapped with unaligned ends with standard read mappers, and thus will leave a weaker unaligned end signal in the mappings for the Structural Variation tool to work with.

In its current version the InDels and Structural Variants tool has the following known limitations:

- It will only detect intra-chromosomal structural variants.

26.12.1 Run the InDels and Structural Variants tool

To start the structural variant detection:

Toolbox | Resequencing Analysis | InDels and Structural Variants tool

This will open up a dialog. Select the read mapping of interest as shown in figure 26.39 and click on the button labeled Next.

Figure 26.39: Select the read mapping of interest.

The next wizard step (Figure 26.40) is concerned with specifying parameters related to the algorithm used for calling structural variants. The algorithm first identifies positions in the mapping(s) with an excess of reads with left (or right) unaligned ends. Once these positions and the consensus sequences of the unaligned ends are determined, the algorithm maps the determined consensus sequences to the reference sequence around other positions with unaligned ends. If mappings are found that are in accordance with a 'signature' of a structural variant, a structural variant is called. For further details about the algorithm see section 26.12.3.

The 'Significance of unaligned end breakpoints' parameters are concerned with when a position with unaligned ends should be considered by the algorithm, and when it should be ignored:

- **P-value threshold**: Only positions in which the fraction of reads with unaligned ends is sufficiently high will be considered. The 'P-value threshold' determines the cut-off value in a Binomial Distribution for this fraction. The higher the P-value threshold is set, the more unaligned breakpoints will be identified.

- **Maximum number of mismatches**: The 'Maximum number of mismatches' parameter determines which reads should be considered when inferring unaligned end breakpoints. Poorly map reads tend to have many mis-matches and unaligned ends, and it may be preferable to let the algorithm ignore reads with too many mis-matches in order to avoid false positives and reduce computational time. On the other hand, if the allowed number of mis-matches is set too low, unaligned end breakpoints in proximities of other variants
(e.g. SNVs) may be lost. Again, the higher the number of mis-matches allowed, the more unaligned breakpoints will be identified.

The Calculation of unaligned end consensus parameters can improve the calculation of the unaligned end consensus by removing bases according to:

- **Minimum quality score**: quality score under which bases should be ignored.
- **Minimum relative consensus coverage**: consensus coverage threshold under which bases should be ignored. The relative consensus coverage is calculated by taking the coverage at the current nucleotide position and dividing by the maximum coverage obtained along the unaligned ends upstream from this position. When the value thus calculated falls below the specified threshold, consensus generation stops. The idea behind the "Minimum relative consensus coverage" option is to stop consensus generation when dramatic drops in coverage are observed. For example, a drop from 1000 coverage to 10 coverage would give a relative consensus coverage of \(10/1000 = 0.01\).

The 'Filter variants' parameters are concerned with the amount of evidence for each structural variant required for it to be called:

- **Filter variants**: When the Filter variants box is checked, only variants that are inferred by breakpoints that together are supported by at least the specified Minimum number of reads will be called.
- **Ignore broken pairs**: This option is checked by default, but it can be unchecked to include variants located in broken pairs.

'Reference masking' allows specification of target regions:

- **Restrict calling to target regions**: When specifying a target region track only reads that overlap with at least one of the targets will be examined when the unaligned end breakpoints
are identified. Hence only breakpoints that fall within, or in close proximity of, the targets will be identified (a read may overlap a target, but have an unaligned end outside the target - these are also identified and therefore breakpoints outside, but in the proximity of the target). The runtime will be decreased when you specify a target track as compared to when you do not.

**Note!** As the set of identified unaligned end breakpoints differs between runs where a target region track has been specified and where it has not, the set of predicted indels and structural variants is also likely to differ. This is because the indels and structural variants are predicted from the mapping patterns of the unaligned ends at the set of identified breakpoints. This is also the case even if you restrict the comparison to only involve the indels and structural variants detected within the target regions. You cannot expect these to be exactly the same but you can expect a large overlap.

Specify these settings and click **Next**. The "Results handling" dialog (Figure 26.41) will be opened. The Indels and Structural variants tool has the following output options:

- **Create report** When ticked, a report that summarizes information about the inferred breakpoints and variants is created.
- **Create breakpoints** When ticked, a track containing the detected breakpoints is created.
- **Create InDel variants** When ticked, a variant track containing the detected indels that fulfill the requirements for being 'variants' is created. These include:
  - the detected insertions for which the allele sequence is inferred, but not those for which it is not known, or only partly known. As the algorithm relies on mapping two unaligned ends against each other for detecting insertions *with inferred allele sequence*, the maximum length of these that can potentially be detected depends on (1) the read length and (2) the "length fraction" parameter of the read mapper. With current read lengths and default settings you are unlikely to get insertions *with inferred allele sequence* larger than a couple of hundred, and hence will not see insertions in this track larger than that.
  - medium sized deletions (those between six and 200 bp). All other deletions are put in the "Structural variants" track. The reason for not including all detected deletions in the indel track is that the main intended use of this track is to guide re-alignment. In our experience, the re-alignment algorithm performs best when only including the medium sized events. Notice that, in contrast to insertions, there is no upper limit on the length of deletions *with inferred allele sequence* that the algorithm can detect. This is because the allele sequence is trivial for deletions, whereas for insertions it must be inferred from the nucleotides in the unaligned ends.

See section 26.9.1 for a definition of the requirements for ‘variants’. Note that insertions and deletions that are not included in the InDel track, will be present in the ‘Structural variants track’ (described below).

- **Create structural variations** When ticked, a track containing the detected structural variants is created, including the insertions *with unknown allele sequence* and the deletions that are not included in the "InDel" track.
An example of the output from the InDels and Structural Variant tool is shown in figure 26.42. The output is described in detail in the next section (section 26.12.2).

26.12.2 The Structural Variants and InDels output

The Structural Variants and InDels report

The report gives an overview of the numbers and types of structural variants found in the sample. It contains

- A table with a row for each reference sequence, and information on the number of breakpoint signatures and structural variants found.
A table giving the total number of left and right unaligned end breakpoint signatures found, and the total number of reads supporting them.

A distribution of the logarithm of the sequence complexity of the unaligned ends of the left and right breakpoint signatures (see section 26.12.5 for how the complexity is calculated).

A distribution of the length of the unaligned ends of the left and right breakpoint signatures.

A table giving the total number of the different types of structural variants found.

Plots depicting the distribution of the lengths of structural variants identified.

The Breakpoints track (BP):

The breakpoints track contains a row for each called breakpoint with the following information:

- **Chromosome**: The chromosome on which the breakpoint is located.
- **Region**: The location on the chromosome of the breakpoint.
- **Name**: The type of the breakpoint ('left breakpoint' or 'right breakpoint').
- **p-value**: The p-value (in the Binomial distribution) of the unaligned end breakpoint.
- **Unaligned**: The consensus sequence of the unaligned ends at the breakpoint.
- **Unaligned length**: The length of the consensus sequence of the unaligned ends at the breakpoint.
- **Mapped to self**: If the unaligned end sequence at the breakpoint was found to map back to the reference in the vicinity of the breakpoint itself, a 'Deletion' or 'Insertion' based on 'self-mapping' evidence is called. This column will contain 'Deletion' or 'Insertion' if that is the case, or be empty if the unaligned end did not map back to the reference in the vicinity of the breakpoint itself.
- **Perfect mapped**: The number of 'perfect mapped' reads. This number is intended as a proxy for the number of reads that fit with the reference sequence. When calculating this number we consider all reads that extend across the breakpoint. We ignore reads that are non-specifically mapped, in a broken pair, or has more than the maximum number of mismatches. A read is perfectly mapped if (1) it has no insertions or deletions (mismatches are allowed) and (2) it has no unaligned end.
- **Not perfect mapped**: The number of 'not perfect mapped' reads. This number is intended as a proxy for the number of reads that fit with the predicted indel. When calculating this number we consider all reads that extend across the breakpoint or that has an unaligned end starting at the breakpoint. We ignore reads that are non-specifically mapped, in a broken pair, or has more than the maximum number of mismatches. A read is not perfect mapped if (1) it has an insertion or deletion or (2) it has an unaligned end.
- **Fraction non-perfectly mapped**: the 'Non perfect mapped' divided by the 'Non perfect mapped' + 'Perfect mapped'.
- **Sequence complexity**: The sequence complexity of the unaligned end of the breakpoint (see section 26.12.5 for how the sequence complexity is calculated).
• **Reads**: The number of reads supporting the breakpoint.

Note that typically, breakpoints will be found for which it is not possible to infer a structural variant. There may be a number of reasons for that: (1) the unaligned ends from which the breakpoint signature was derived might not be caused by an underlying structural variant, but merely be due to read mapping issues or noise, or (2) the breakpoint(s) which the detected breakpoint should have been matched to was/were not detected, and therefore no matching breakpoint(s) were found. Breakpoints may go undetected either because of lack of coverage in the breakpoint region or because they are located within regions with exclusively non-uniquely mapped reads (only unaligned ends of uniquely mapping reads are used).

**The InDel variants track (InDel):**

The Indel variants track contains a row for each of the called insertions or deletions that fulfill the requirements for being of a 'variant' type (see section 26.9.3 for a description of the variant types "Insertion" and "Deletion"). These are the small to medium sized insertions and deletions (up to 200 bp in length) for which the algorithm was able to identify the allele sequence (that is, the exact inserted sequence, or the exact deleted sequence). For insertions, the full allele sequence is found from the unaligned ends of mapped reads. For some insertions the length and allele sequence cannot be determined and as these do not fulfill the requirements of a 'variant', they do not qualify for representation in the 'InDel variant' track but instead appear in the Structural Variants track (see below). The information provided for each of the indels in the InDel variant track is the 'Chromosome', 'Region', 'Type', 'Reference', 'Allele', 'Reference Allele', 'Length' and 'Zygosity' columns that are provided for all variants (see section 26.9.1). In addition the following information, which is primarily intended to allow the user to assess the degree of evidence supporting each predicted indel, is provided:

• **Evidence**: The mapping evidence on which the call of the indel was based. This may be either 'Self mapped', 'Paired breakpoint', Cross mapped breakpoint’ or 'Tandem duplication’ depending of the mapping signature of the unaligned ends of the breakpoint(s) from which the indel was inferred.

• **Repeat**: The algorithm attempts to identify if the variant sequence contains perfect repeats. This is done by searching the region around the structural variant for perfect repeat sequences. The region searched is 3 times the length of variant around the insertion/deletion point. The maximum repeat length searched for is 10. If a repeat sequence is found, the repeated sequence is given in this column. If not, the column is empty.

• **Variant ratio**: This column contains the sum of the 'Non perfect mapped' reads for the breakpoints used to infer the indel, divided by the sum of the 'Non perfect mapped' and 'Perfect mapped' reads for the breakpoints used to infer the indel (see section the description above of the breakpoints track). This fraction is intended to give a hint towards the zygosity of the indel. The closer the value to 1, the higher the likelihood that the variant is homozygous.

• **# Reads**: The total number of reads supporting the breakpoints from which the indel was constructed.
• **Sequence complexity**: The sequence complexity of the unaligned end of the breakpoint (see section 26.12.5). Indels with higher complexity are typically more reliable than those with low complexity.

The 'Zygosity' field is set to 'Homozygous' if the 'Variant ratio' is 0.80 or above, and 'Heterozygous' otherwise.

**The Structural variants track (SV):**

The Structural variants track contains a row for each of the called Structural variants that is not already reported in the InDel track. It contains the following information:

- **Chromosome**: The chromosome on which the structural variant is located.
- **Region**: The location on the chromosome of the structural variant.
- **Name**: The type of the structural variant ('deletion', 'insertion', 'inversion', 'replacement', 'translocation' or 'complex').
- **Evidence**: The breakpoint mapping evidence ('that is, the 'unaligned end 'signature') on which the call of the structural variant was based. This may be either 'Self mapped', 'Paired breakpoint', 'Cross mapped breakpoints', 'Cross mapped breakpoints (invalid orientation)', 'Close breakpoints', 'Multiple breakpoints' or 'Tandem duplication', depending on which type of signature that was found.
- **Length**: the length of the allele sequence of the structural variant. Note that the length of variants for which the allele sequence could not be determined is reported as 0 (e.g. insertions inferred from 'Close breakpoints').
- **Reference sequence**: The sequence of the reference in the region of the structural variant.
- **Variant sequence**: The allele sequence of the structural variant if it is known. If not, the column will be empty.
- **Repeat**: The same as in the InDel track.
- **Variant ratio**: The same as in the InDel track.
- **Signatures**: The number of unaligned breakpoints involved in the signature of the structural variant. In most cases these will be pairs of breakpoints, and the value is 2, however some structural variants that have signatures involving more than two breakpoint (See section 26.12.4). Typically structural variants of type 'complex' will be inferred from more than 2 breakpoint signatures.
- **Left breakpoints**: The positions of the 'Left breakpoints' involved in the signature of the structural variant.
- **Right breakpoints**: The positions of the 'Right breakpoints' involved in the signature of the structural variant.
- **Mapping scores fraction**: The mapping scores of the unaligned ends for each of the breakpoints. These are the similarity values between the unaligned end and the region of the reference to which it was mapped. The values lie between 0 and 1. The closer the value is to 1, the better the match, suggesting better reliability of the inferred variant.
- **Reads**: The total number of reads supporting the breakpoints from which the indels was constructed.

- **Sequence complexity**: The sequence complexity of the unaligned end of the breakpoint (see section 26.12.5).

- **Split group**: Some structural variants extend over a very large a region. For these visualization is challenging, and instead of reporting them in a single row we split them in multiple rows - one for each ‘end’ of the variant. To allow the user to see which of these ‘split features’ belong together, we give features that belong to the same structural variant a common ‘split group’ identifier. If the column is empty the structural variant is not split, but contained within a single row.

26.12.3 The InDels and Structural Variants detection algorithm

The Indels and Structural Variants detection algorithm has two steps:

1. Identify 'breakpoint signatures': First, the algorithm identifies positions in the mapping(s) with an excess of reads with left (or right) unaligned ends. For each of these, it creates a Left breakpoint (LB) or Right breakpoint (RB) signature.

2. Identify 'structural variant signatures': Secondly, the algorithm creates structural variant signatures from the identified breakpoint signatures. This is done by mapping the consensus unaligned ends of the identified LB and RB signatures to selected areas of the references as well as to each other. The mapping patterns of the consensus unaligned ends are examined and structural variant annotations consistent with the mapping patterns are created.

The two steps of the algorithm are described in detail in sections 26.12.3 and 26.12.3.

**Step 1: Creating Left- and Right breakpoint signatures**

In the first step of the InDels and Structural Variants detection algorithm points in the read mapping are identified which have a significant proportion of reads mapped with unaligned ends. There are typically numerous reads with unaligned ends in read mappings — some are due to structural variants in the sample relative to the reference, others are due to poorly mapped, or poor quality reads. An example is given in figure 26.43. In order to make reliable predictions, attempts must be made to distinguish the unaligned ends caused by noisy read(mappings) from those caused by structural variants, so that the signal from the structural variants comes through as clearly as possible — both in terms of where the ‘significant’ unaligned ends are and in terms of what they look like.

To identify positions with a ‘significant’ portion of ‘consistent’ unaligned end reads we first estimate ‘null-distributions’ of the fractions of left and right unaligned end reads at each position in the read mapping, and subsequently use these distributions to identify positions with an ‘excess’ of unaligned end reads. In these positions we create a Left (LB) or Right (RB) breakpoint signature. To estimate the null-distributions we:

1. Calculate the coverage, \( c_i \), in each position, \( i \) of all uniquely mapped reads (Non-specifically mapped reads are ignored. Furthermore, for paired read data sets, only intact paired reads pairs are considered — broken paired reads are ignored).
2. Calculate the coverage in each position of 'valid' reads with a starting left unaligned end, $l_i$ (of minimum consensus length 3bp).

3. Calculate the coverage in each position of 'valid' reads with a starting right unaligned end, $r_i$ (of minimum consensus length 3bp).

We then use the observed fractions of 'Left unaligned ends' ($\frac{\sum_i l_i}{\sum_i c_i}$) and 'Right unaligned ends' ($\frac{\sum_i r_i}{\sum_i c_i}$) as frequencies in binomial distributions of 'Left unaligned end' and 'Right unaligned end' read fractions. We go through each position in the read mapping and examine it for an excess of left (or right) unaligned end reads: if the probability of obtaining the observed number of left (or right) unaligned ends in a position with the observed coverage, is 'small', a Left breakpoint signature (LB), respectively Right breakpoint signature (RB), is created.

The two user-specified settings 'The P-value threshold' and the 'Maximum number of mismatches' determine which breakpoint signatures the algorithm will detect (see section 26.12.1 and figure 26.40). The p-value is used as a cutoff in the binomial distributions estimated above: if the probability of obtaining the observed number of left (or right) unaligned ends in a position with the observed coverage, is smaller than the user-specified cut-off, a Left breakpoint signature (LB), respectively Right breakpoint signature (RB), is created. The 'Maximum number of mismatches' parameter is used to determine which reads are considered 'valid' unaligned end reads. Only reads that have at most this number of mis-matches in their aligned parts are counted. The higher these two values are set, the more breakpoints will be called. The more breakpoints are called, the larger the search space for the Structural variation detection algorithm, and thus the longer the computation time.

In figure 26.43, three unaligned end signatures are shown. The left-most LB signature is called only when the p-value cut-off is chosen high (0.01 as opposed to 0.0001).

**Step 2: Creating Structural variant signatures**

In the second step of the InDels and Structural Variants detection algorithm the unaligned end 'breakpoint signatures' (identified in step 1) are used to derive 'structural variant signatures'. This is done by:

1. Generating a consensus sequence of the reads with unaligned ends at each identified breakpoint.
2. Mapping the generated consensus sequences against the reference sequence in the regions around other identified breakpoints (‘cross-mapping’).

3. Mapping the generated consensus sequences of breakpoints that are near each other against each other (‘aligning’).

4. Mapping the generated consensus sequences against the reference sequence in the region around the breakpoint itself (‘self-mapping’).

5. Considering the breakpoints whose unaligned end consensus sequences are found to cross map against each other together, and compare their mapping patterns to the set of theoretically expected ‘structural variants signatures’ (see section 26.12.4).

6. Creating a ‘structural variant signature’ for each of the groups of breakpoints whose mapping patterns were in accordance with one of the expected ‘structural variants signatures’.

A structural variant is called for each of the created ‘structural variant signatures’. For each of the groups of breakpoints whose mapping patterns were NOT in accordance with one of the expected ‘structural variants signatures’, we call a structural variant of type ‘complex’.

The steps above require a number of decisions to be made regarding (1) When is the consensus sequence reliable enough to work with?, and (2) When does an unaligned end map well enough that we will call it a match? The algorithm uses a number of hard-coded values when making those decisions. The values are described below.

Algorithmic details

- **Generating a consensus**: The consensus of the unaligned ends is calculated by simple alignment without gaps. Having created the consensus, we exclude the unaligned ends which differ by more than 20% from the consensus, and recalculate the consensus. This prevents ‘spuriously’ unaligned ends that extend longer than other unaligned ends from impacting the tail of the consensus unaligned end.

- **Mapping of the consensus**:

  - ‘Cross mapping’: When mapping the consensus sequences against the reference sequence around other breakpoints we require that:
    - The consensus is at least 16 bp long.
    - The score of the alignment is at least 70% of the maximal possible score of the alignment.

  - ‘Aligning’: When aligning the consensus sequences two closely located breakpoints against each other we require that:
    - The breakpoints are within a 100 bp distance of each other.
    - The overlap in the alignment of the consensus sequences is least 4 nucleotides long.

  - ‘Self-mapping’: When mapping the consensus sequences of breakpoints against the reference sequence in a region around the breakpoint itself we require that:
    - The consensus is at least 9 bp long.
    - A match is found within 400 bp window of the breakpoint.
The score of the alignment is at least 90% of the maximal possible score of the alignment of the part of the consensus sequence that does not include the variant allele part.

### 26.12.4 Theoretically expected structural variant signatures

Different types of structural variants will leave different 'signatures' in terms of the mapping patterns of the unaligned ends. The 'structural variant signatures' of the set of structural variants that are considered by the Indels and Structural variant tool are drawn in figures 26.44, 26.45, 26.46, 26.47, 26.48, 26.49, 26.50, 26.51 and 26.52.

**Figure 26.44: A deletion with cross-mapping breakpoint evidence.**

**Figure 26.45: A deletion with selfmapping breakpoint evidence.**
CHAPTER 26. VARIANT DETECTION

**Figure 26.46:** An insertion with close breakpoint evidence.

**Figure 26.47:** An insertion with cross-mapped breakpoints evidence.

**Figure 26.48:** An insertion with selfmapped breakpoint evidence.
CHAPTER 26. VARIANT DETECTION 692

Figure 26.49: An *insertion* with breakpoint mapping evidence corresponding to a ‘Tandem duplication’.

**Insertion - tandem duplication**

- Sample reads map to the reference genome between points A and B.
- Unaligned ends are detected before A and after B.
- Unaligned ends map before B and after A.
- Conclusion: Sample genome contains a tandem duplication insertion.

Figure 26.50: The unaligned end mapping pattern of an inversion.

**Inversion - crossmapped/paired breakpoints**

- Unaligned ends are detected at two positions.
- Unaligned ends from point A map at B reverse translated and vice versa.
- Conclusion: The sample genome contains an inversion of the region between A and B.

Figure 26.51: The unaligned end mapping pattern of a replacement.

**Replacement**

- Unaligned ends are detected between A and B.
- Unaligned ends map to each other.
- The consensus alignment of the reads map to the reference with a replaced internal sequence.
- Conclusion: Sample genome contains a replacement between points A and B.
Figure 26.52: The unaligned end mapping pattern of a translocation.

Translocation

Unaligned ends are detected at three positions.

The unaligned ends map to other places around the same three positions in the specific pattern shown here.

Conclusion: The sample genome contains a translocation (the part between A and B in the sample has been deleted, and re-inserted at the point C in the sample).
26.12.5 How sequence complexity is calculated

The sequence complexity of an unaligned end is calculated as the product of ‘the observed vocabulary-usages’ divided by ‘the maximal possible vocabulary-usages’, for word sizes from one to seven. When multiple breakpoints are used to construct a structural variant, the complexity is calculated as the product of the individual sequence complexities of the breakpoints constituting the structural variant.

The observed vocabulary usage for word size, k, for a given sequence is the number of different "words" of size k that exist in that sequence. The maximal possible vocabulary usage for word size k for a given sequence is the maximal number of different words of size k that can possibly be observed in a sequence of a given length. For DNA sequences, the set of all possible letters in such words is four, that is, there are four letters that represent the possible nucleotides: A, C, G and T. The calculation is most easily described using an example.

Consider the sequence CAGTACAG. In this sequence we observe:

- 4 different words of size 1 (‘A’, ‘C’, ‘G’ and ‘T’).
- 5 different words of size 2 (‘CA’, ‘AG’, ‘GT’, ‘TA’ and ‘AC’) Note that ‘CA’ and ‘AG’ are found twice in this sequence.
- 5 different words of size 3 (‘CAG’, ‘AGT’, ‘GTA’, ‘TAC’ and ‘ACA’) Note that ‘CAG’ is found twice in this sequence.
- 5 different words of size 4 (‘CAGT’, ‘AGTA’, ‘GTAC’, ‘TACA’ and ‘ACAG’)
- 4 different words of size 5 (‘CAGTA’, ‘AGTAC’, ‘GTACA’ and ‘TACAG’)
- 3 different words of size 6 (‘CAGTAC’, ‘AGTACA’ and ‘GTACAG’)
- 2 different words of size 7 (‘CAGTACA’ and ‘AGTACAG’)

Note that we only do the calculations for word sizes up to 7, even when the unaligned end is longer than this.

Now we consider the maximal possible number of words we could observe in a DNA sequence of this length, again restricting our considerations to word of size of 7.

- Word size of 1: The maximum number of different letters possible here is 4, the single characters, A, G, C and T. There are 8 positions in our example sequence, but there are only 4 possible unique nucleotides.
- Word size of 2: The maximum number of different words possible here is 7. For DNA generally, there is a total of 16 different dinucleotides (4*4). For a sequence of length 8, we can have a total of 7 dinucleotides, so with 16 possibilities, the dinucleotides at each of our 7 positions could be unique.
- Word size of 3: The maximum number of different words possible here is 6. For DNA generally, there is a total of 64 different dinucleotides (4*4*4). For a sequence of length 8, we can have a total of 6 trinucleotides, so with 64 possibilities, the trinucleotides at each of our 6 positions could be unique.
• Word size of 4: The maximum number of different words possible here is 5. For DNA generally, there is a total of 256 different dinucleotides \((4^2)^4\). For a sequence of length 8, we can have a total of 5 quaternucleotides, so with 256 possibilities, the quaternucleotides at each of our 5 positions could be unique.

We then continue, using the logic above, to calculate a maximum possible number of words for a word size of 5 being 4, a maximum possible number of words for a word size of 6 being 3, and a maximum possible number of words for a word size of 7 being 2.

Now we can compute the complexity for this 7 nucleotide sequence by taking the number of different words we observe for each word size from 1 to 7 nucleotides and dividing them by the maximum possible number of words for each word size from 1 to 7. Here that gives us:

\[
\frac{4}{4} \cdot \frac{5}{6} \cdot \frac{5}{5} \cdot \frac{4}{4} \cdot \frac{3}{3} \cdot \frac{2}{2} = 0.595
\]

As an extreme example of a sequence of low complexity, consider the 7 base sequence AAAAAAA. Here, we would get the complexity:

\[
\frac{1}{4} \cdot \frac{1}{6} \cdot \frac{1}{5} \cdot \frac{1}{4} \cdot \frac{1}{3} \cdot \frac{1}{2} \cdot \frac{1}{1} = 0.000347
\]

In the CLC Genomics Workbench resequencing is the overall category for applications comparing genetic variation of a sample to a reference sequence. This can be targeted resequencing of a single locus or whole genome sequencing. The overall workflow will typically involve read mapping, some sort of variant detection and interpretation of the variants.

This chapter describes the tools relevant for the resequencing workflows downstream from the actual read mapping which is described in chapter 25.

27.1 Quality Control for resequencing analyses

27.1.1 QC for Targeted Sequencing

This tool is designed to report the performance (enrichment and specificity) of a targeted re-sequencing experiment. Targeted re-sequencing is due to its low costs, very popular and several companies provide platforms and protocols (learn more at http://en.wikipedia.org/wiki/Exome_sequencing#Target-enrichment_strategies). Array-based approaches are offered by e.g. Agilent (SureSelect) and Roche Nimblegen. Furthermore, amplicon sequencing with PCR primers is offered by RainDance, Fluidigm and others.

Given an annotation track with the target regions (e.g. imported from a bed file), this tool will investigate a read mapping to determine whether the targeted regions have been appropriately covered by sequencing reads as well as information about how specific the reads map to the targeted regions. The results are provided both as a summary report and as track or table with detailed information about each targeted region.

Note! This tool is for re-sequencing data only; if you have RNA-seq data, please see section 28.1.

Running the QC for Targeted Sequencing

To create the target regions statistics:

Toolbox | Resequencing Analysis | QC for Targeted Sequencing

This opens a wizard where you can select mapping results as seen in figure 27.1.

Figure 27.1: Select a read mapping.

Clicking Next will take you to the wizard shown in figure 27.2.

Click the Browse icon to select an annotation track that defines the targeted regions of your reference genome. You can either import the target regions as an annotation file (see section 6.2) or convert (see section 23.5) from annotations on a reference genome that is already stored in the Navigation Area.
CHAPTER 27. RESEQUENCING

Figure 27.2: Specifying the track of target regions.

The **Report type** allows you to select different sets of predefined coverage thresholds to use for reporting (see below). Furthermore, you will be asked to provide a **Minimum coverage** threshold, i.e., the minimum coverage needed on all positions in a target, in order for that target to be considered covered.

Finally, you are asked to specify whether you want to ignore **non-specific matches** and **ignore broken pairs**. When these are applied reads that are non-specifically mapped or belong to broken pairs will be ignored.

Click **Next** to specify the type of output you want (see figure 27.3).

Figure 27.3: Specifying how the result should be reported.

There are three options:

- The report gives an overview of the whole data set as explained in section 27.1.1.
- The track gives information on coverage for each target region as described in section 27.1.1.
- The coverage table outputs coverage for each position in all the targets as described in section 27.1.1.
- The coverage graph outputs a graphical presentation of the coverage for each position in all the targets. Positions outside the targets will have the value 0. The values are calculated
by the "Target regions statistics" tool - that is, where broken pairs and multi-hit reads are included or ignored, depending upon what the user has specified in the wizard. On the x-axis is the reference position; on the y-axis is the coverage. The x-axis and y-axis values are identical to those found in the corresponding columns of the coverage table.

Click **Finish** to create the selected reports.

**Coverage summary report**

An example of a coverage report is shown in figure 27.4).

![Image of coverage report table]

**Figure 27.4: The report with overviews of mapped reads.**

This figure shows only the top of the report. The full content is explained below:

**Coverage summary** This table shows overall coverage information.

- **Number target regions** The number of targeted regions.
- **Total length of target regions** The sum of the size of all the targeted regions (this means it is calculated from the annotations alone and is not influenced by the reads).
Average coverage For each position in each target region the coverage is calculated, and stored (you can see the individual coverages in the Coverage table output, figure 27.9). The ‘average coverage’ is calculated by taking the mean of all the calculated coverages in all the positions in all target regions. Note that if the user has chosen ignore non-specific matches or ignore broken pairs these reads will not contribute to the coverage. Note also that bases in over-lapping paired reads will only be counted as 1.

Number of target regions with low coverage The number of target regions which have positions with a coverage that is below the user-specified Minimum coverage threshold.

Total length of target regions with low coverage The total length of these regions.

Fractions of targets with coverage at least... This table shows how many target regions have a certain percentage of the region above the user-specified Minimum coverage threshold.

Fractions of targets with coverage at least... A histogram presentation of the table above in Fractions of targets with coverage at least....

Coverage of target regions positions This plot shows the coverage level on the x axis, and the number of positions in the target regions with that coverage level.

Coverage of target regions positions A version of the histogram above zoomed in to the values that lie + 3SDs from the median.

Minimum coverage of target regions This shows the percentage of the targeted regions that are covered by this many bases. The intervals can be specified in the dialog when running the analysis. Default is 1, 5, 10, 20, 40, 80, 100 times. In figure 27.5 this means that 26.58 % of the positions on the target are covered by at least 40 bases.

Targeted regions overview This section contains two tables: one that summarizes, for each reference sequence, information relating to the reads mapped, and one that summarizes, for each reference, information relating to the bases mapped (figures 27.5 and 27.6). Note that, for the table that is concerned with reads, reads in over-lapping pairs are counted individually. Also note that, for the table that is concerned with bases, bases in overlapping paired reads are counted only as one (Examples are given in figures 27.7 and figure 27.8).

Reference The name of the reference sequence.

Total mapped reads The total number of mapped reads on the reference, including reads mapped outside the target regions.

Mapped reads in targeted region Total number of reads in the targeted regions. Note that if there are overlapping regions, reads covered by two regions will be counted twice. If a read is only partially inside a targeted region, it will still count as a full read.

Specificity The percentage of the total mapped reads that are in the targeted regions.

Total mapped reads excl ingored The total number of mapped reads on the reference, including reads mapped outside the target regions, excluding the non-specific matches or broken pairs, if the user has switched on the option to ignore those.

Mapped reads in targeted region excl ingored Total number of reads in the targeted regions, excluding the non-specific matches or broken pairs, if the user has switched on the option to ignore those.
Specificity excl ingored  The percentage of the total mapped reads that are in the targeted regions.

Reference  The name of the reference sequence.

Total mapped bases  The total number of mapped bases on the reference, including bases mapped outside the target regions.

Mapped bases in targeted region  Total number of bases mapped within in the targeted regions. Note that if there are overlapping regions, bases included in two regions will be counted twice.

Specificity  The percentage of the total mapped bases that are in the targeted regions.

Total mapped bases excl ingored  The total number of mapped bases on the reference, including bases mapped outside the target regions, excluding the bases in non-specific matches or broken pairs, if the user has switched on the option to ignore those.

Mapped bases in targeted region excl ingored  Total number of bases in the targeted regions, excluding the bases in non-specific matches or broken pairs, if the user has switched on the option to ignore those.

Specificity excl ingored  The percentage of the total mapped bases that are in the targeted regions.

Distribution of target region length  A plot of the length of the target regions, and a version of the plot where only the target region lengths that lie within +3SDs of the median target length are shown.

Base coverage  The percentage of base positions in the target regions that are covered by respectively 0.1, 0.2, 0.3, 0.4, 0.5 and 1.0 times the mean coverage, where the mean coverage is the average coverage given in table 1.1. Because this is based on mean coverage, the numbers can be used for cross-sample comparison of the quality of the experiment.

Base coverage plot  A plot showing the relationship between fold mean coverage and the number of positions. This is a graphical representation of the Base coverage table above.

Mean coverage per target position  Three plots listing the mean coverage for each position of the targeted regions. The first plot shows coverage across the whole target, using a percentage of the target length on the x axis (to make it possible to have targets with different lengths in the same plot). This is reported for reverse and forward reads as well. In addition, there are two plots showing the same but with base positions on the x axis counting from the start and end of the target regions, respectively. These plots can be used to evaluate whether there is a general tendency towards lower coverage at the end of the targeted region, and whether there is a bias in terms of forward and reverse reads coverage.

Read count per %GC  The plot shows the GC content of the reference sequence on the X-axis and the number of mapped reads on the Y-axis. This plot will show if there is a basis caused by higher GC-content in the sequence.
Per-region statistics

In addition to the summary report, you can see coverage statistics for each targeted region. This is reported as a track, and you can see the numbers by going to the table view of the track. An example is shown in figure 27.7:

Chromosome The name is taken from the reference sequence used for mapping.

Region The targeted region.

Name The annotation name derived from the annotation (if there is additional information on the annotation, this is retained in this table as well).

Target region length The length of the region.

Target region length with coverage above... The length of the region that is covered by at least the Minimum coverage level provided in figure 27.2.
**Percentage with coverage above...** The percentage of the positions in the region with coverage at least the **Minimum coverage** level provided in figure 27.2.

**Read count** Number of reads that cover this region. Note that reads that only cover the region partially are also included. Note that reads in over-lapping pairs are counted individually (see figures 27.7 and figure 27.8).

**Base count** The number of bases in the reads that are covering the target region. Note that bases in overlapping pairs are counted only once (see figures 27.7 and figure 27.8).

**%GC** The GC content of the region.

**Min coverage** The lowest coverage in the region.

**Max coverage** The highest coverage in the region.

**Mean coverage** The average coverage in the region.

**Median coverage** The median coverage in the region.

**Zero coverage bases** The number of positions with no coverage.

**Mean coverage (excluding zero coverage)** The average coverage in the region, excluding any zero-coverage parts.

**Median coverage (excluding zero coverage)** The median coverage in the region, excluding any zero-coverage parts.

Figure 27.7: A track list containing the target region coverage track and reads track. The target region coverage track has been opened from the track list and is shown in table view. Detailed information on each region is displayed. Only one paired read maps to the region selected.

In the shown figure, the coverage table is shown in split view with a track list. The coverage track has been opened from the track list by clicking once on the name found in the left side in the track list. When opening a read mapping in split view from a track list, the two views are linked, this means that when you click on an entry in the table, this position will be brought into focus in the track list.

For information about how to create a track list, please see section 23.2.
CHAPTER 27. RESEQUENCING

Figure 27.8: The same data as shown in figure 27.7, but now the Disconnect paired reads option in the side-panel of the reads track has been ticked, so that the two reads in the paired read are shown disconnected.

Coverage table

Besides standard information such as position etc, the coverage table (figure 27.9) lists the following information for each position in the whole target:

Name The name of the target region.

Target region position The name of the target region.

Reference base The base in the reference sequence.

Coverage The number of bases mapped to this position. Note that bases in over-lapping pairs are counted only once. Also note that if the user has chosen the Ignore non-specific matches or Ignore broken pairs options, these reads will be ignored. (see discussion on coverage in section 27.1.2).

In the shown figure, the coverage table is shown in split view with a track list. The coverage track has been opened from the track list by clicking once on the name found in the left side in the track list. When opening a read mapping in split view from a track list, the two views are linked, this means that when you click on an entry in the table, this position will be brought into focus in the track list.

For information about how to create a track list, please see section 23.2.

Coverage graph

The coverage graph is a graphical presentation of the coverage for each position in all the targets (positions outside the targets will have the value 0). The values are calculated by the "Target regions statistics" tool, and are presented with the reference position on the x-axis and the coverage on the y-axis (see figure 27.10). The x-axis and y-axis values are identical to those found in the columns of the coverage table.
27.1.2 QC for Read Mapping

Note that this tool can be used to create a detailed report on a read mapping or a de novo assembly.

To create a detailed mapping report:

**Toolbox | Resequencing Analysis | Quality Control | QC for Read Mapping**

This opens a dialog where you can select mapping results (/) or RNA-Seq analysis results (/).

Clicking **Next** will display the dialog shown in figure 27.11.

In the next wizard window "Set contig group", you can set thresholds for grouping long and short contigs. The grouping is used to show statistics like number of contigs, mean length etc. for the contigs in each group. Thresholds can only be specified for de novo assemblies that do not
have a consensus sequence, i.e., these options are disabled whenever a consensus sequence is present or if you are working with a read mapping. Note that the de novo assembly in the CLC Genomics Workbench per default only reports contigs longer than 200 bp (this can be changed when running the assembly).

Click **Next** to select output options as shown in figure 27.12

By checking "Create table with statistics for each mapping", you can create a table showing detailed statistics for each reference sequence (for de novo results the contigs act as reference sequences, so it will be one row per contig).

The first section of the detailed report is a summary of the statistics: reference count, type, total reference length, GC contents in %, total read count, mean read length, and total read length

- Reference count
- Type
- Total reference length
- GC contents in %
- Total read count
- Mean read length
• Total read length

The rest of the report, as well as the optional statistic tables are described in the following sections.

Reference sequence

The second section of the detailed report concerns the Reference sequence(s).

First, a table gives information about Reference coverage, including coverage statistics and GC content of the reference sequence.

The second table gives Coverage statistics. A position on the reference is counted as "covered" when at least one read is aligned to it. Note that unaligned ends (faded nucleotides at the ends) that are produced when mapping using local alignment do not contribute to the coverage. Also, positions with an ambiguous nucleotide in the reference (i.e., not A, C, T or G) count as zero coverage regions, regardless of the number of reads mapping across them.

In the example shown in figure 27.13, there is a region of zero coverage in the middle and one time coverage on each side. Note that the gaps to the very right are within the same read which means that these two positions on the reference sequence are still counted as "covered”.

![Figure 27.13: A region of zero coverage in the middle and one time coverage on each side. Note that the gaps to the very right are within the same read which means that these two positions on the reference sequence are still counted as "covered".](image)

In this table, coverage is reported on two levels: including and excluding zero coverage regions. In some cases, you do not expect the whole reference to be covered, and only the coverage levels of the covered parts of the reference sequence are interesting. On the other hand, if you have sequenced the full genome that you use as reference, the overall coverage is probably the most relevant number (i.e. including zero coverage regions).

In the third and fourth subsections, two graphs display Coverage level distribution, with and without zero coverage regions. Two bar plots show the distribution of coverage with coverage level on the x-axis and number of positions with that coverage on the y-axis (as seen in figure 27.14).

The graph to the left shows all the coverage levels, whereas the graph to the right shows coverage levels within 3 standard deviations from the mean. The reason for this is that for complex genomes, you will often have a few regions with extremely high coverage which will affect the resolution of the graph, making it impossible to see the coverage distribution for the majority of the references. These coverage outliers are excluded when only showing coverage within 3
standard deviations from the mean. Below the second coverage graph there are some statistics on the data that is outside the 3 standard deviations.

Subsection 5 gives some statistics on the **Zero coverage regions**; the number, minimum and maximum length, mean length, standard deviation, and total length.

One of the biases seen in sequencing data concerns GC content. Often there is a correlation between GC content and coverage. In order to investigate this correlation, the report includes in subsection 6 a **Coverage versus GC Content** graph plotting coverage against GC content (see figure 27.15). Note that you can see the GC content for each reference sequence in the table(s) above.

The plot displays, for each GC content level (0-100 %), the mean read coverage of 100bp reference segments with that GC content.
For a report created from a de novo assembly, this section finishes with statistics about the reads which are the same for both reference and de novo assembly (see section 27.1.2 below).

Read statistics

This section contains simple statistics for all mapped reads, non-specific matches (reads that match more than place during the assembly), non-perfect matches (reads with one or more mismatches or gaps relative to the reference sequence) and paired reads.

Note! Paired reads are counted as two, even though they form one pair. The section on paired reads also includes information about paired distance and counts the number of pairs that were broken due to:

- Wrong distance: When starting the mapping, a distance interval is specified. If the reads during the mapping are placed outside this interval, they will be counted here.
- Mate inverted: If one of the reads has been matched as reverse complement, the pair will be broken (note that the pairwise orientation of the reads is determined during import).
- Mate on other contig: If the reads are placed on different contigs, the pair will also be broken.
- Mate not matched: If only one of the reads match, the pair will be broken as well.

Each subsection contains a table that recapitulates the read count, % of all mapped reads, mean read length and total read length, and for some sections two graphs showing the distribution of match specificity or the distribution of mismatches.

Note that for the section concerning paired reads (see figure 27.16), the distance includes both the read sequence and the insert between them as explained in section 6.3.7.

![Paired-end distance distribution](image)

Figure 27.16: A bar plot showing the distribution of distances between intact pairs.

The following subsections give graphs showing read length distribution, insertion length distribution, deletion length distribution. Two plots of the distribution of insertion and deletion lengths can be seen in figure 27.17 and figure 27.18.

Nucleotide differences in reads relative to a reference gives the percentage of read bases that differ with the reference for all base pairs and a deletion. In the Nucleotide mapping section
two tables give the counts and percentages of differences between the reads and the reference for each base. Graphs display the relative errors and errors counts between reads to reference and reference to reads, i.e., which bases in the reference are substituted to which bases in the reads. This information is plotted in different ways with an example shown here in figure 27.17.

Figure 27.17: The As and Ts are more often substituted with a gap in the sequencing reads than C and G.

This example shows for each type of base in the reference sequence, which base (or gap) is found most often. Please note that only mismatches are plotted - the matches are not included. For example, an A in the reference is more often replaced by a G than any other base.

Below these plots, there are two plots of the quality values for matches and quality values for mismatches. Next, there is a plot of the mismatch fraction for each read position. Typically with quality dropping towards the end of a read, there will be more mismatches towards the end as the example in figure 27.18 shows.

Figure 27.18: There are mismatches towards the end of the reads.

The last plots section deals with unaligned read lengths.
CHAPTER 27. RESEQUENCING

Statistics table for each mapping

By checking "Create table with statistics for each mapping", a table showing detailed statistics for each reference sequence will be generated (figure 27.19).

Figure 27.19: Statistics table for a read mapping.

- Contig
- Reference name, Latin name, description, length
- Mapped reads
- Forward and Reverse reads
- Reads in aligned pairs
- Reads in broken pairs: wrong distance or mate inverted, mate on other contig, mate not mapped
- Average distance
- Standard deviation distance. Standard deviation of the mapped pairs distances.
- Non-specific and non-perfect matches
- Minimum, maximum, average coverage
- Standard deviation coverage. Standard deviation of the per base coverage.
- Minimum, average coverage excluding zero coverage regions
- Standard deviation excluding zero coverage regions. Standard deviation of the per base coverage, excluding regions without coverage.
- % GC. GC content of the reference sequence.
- Consensus length
- Fraction of reference covered
- Count (zero coverage regions)
- Minimum, maximum, average and total length (zero coverage regions)
- Standard deviation length (zero coverage regions). Standard deviation of the distribution of the lengths of all the zero coverage regions on that contig.
27.1.3 Whole Genome Coverage Analysis

The Whole Genome Coverage Analysis tool is designed to identify regions in read mappings with unexpectedly low or high coverage. Such regions may be indicative of a deletion or an amplification in the sample relative to the reference. The algorithm fits a Poisson distribution to the observed coverage in the positions of the mapping. This distribution is used as the basis for identifying the regions of 'Low coverage' or 'High coverage'. The user chooses two parameter values in the wizard: (1) a 'Minimum length' and (2) a 'P-value threshold' value. The algorithm inspects the coverage in each of the positions in the read mapping and marks the ones with coverage in the lower or upper tails of the estimated Poisson distribution, using the provided p-value as cut-off. Regions with consecutive positions marked consistently as having low (respectively high) coverage, longer than the user specified 'Minimum length' value are called as 'Low coverage' (respectively 'High coverage') regions.

To run the Whole Genome Coverage Analysis tool:

Toolbox | Resequencing Analysis ( ) | Whole Genome Coverage Analysis ( )

In the first dialog, select a reads track or read mapping and click Next. This opens the dialog shown in figure 27.20.

![Figure 27.20: Specify the p-value cutoff.](image)

Set the p-value and minimum length cutoff. Click Next and specify the result handling (figure 27.21).

![Figure 27.21: Specify the output.](image)

Selecting the "Create report" will generate the report made of 2 tables (figure 27.22). The first one, called References, lists per chromosome the number of reads, their length, and how many signatures of unexpectedly low or high coverage was found in the mapping. The second table
lists on 2 rows low and high coverage signatures found, as well as how many reads were used to calculate these signatures.

![Table output](image1.png)

**Figure 27.22: The report output.**

Selecting the "Create regions" will generate the annotation track carrying the name of the original file followed by (COV). This file can be visualized as an annotation track or as a table depending on the users choice. The annotation table contains a row for each detected low or high coverage region, with information describing the location, the type and the p-value of the detected region. The p-value of a region is defined as the average of the p-values calculated for each of the positions in the region.

An example of a track output of the Whole Genome Coverage Analysis tool is shown in figure 27.23.

![Table output with detailed information](image2.png)

**Figure 27.23: The table output with detailed information on each region.**

The Whole Genome Coverage Analysis table includes the following columns (figure 27.23):

- **Chromosome** The name is taken from the reference sequence used for mapping
- **Region** The start and end position of this region on the reference sequence
- **Name** The type of annotation: high or low coverage
P-Value  The calculated significance p-value for this region
Length  The length of the region

For the visual inspection and comparison to known gene/transcripts or other kind of annotations, all region are also annotated on the read mapping.

## 27.2 Variant filtering

In addition to the general filter for track tables, including the ability to create a new track from a selection (see section 23.1.2), there are a number of tools for general filtering of variants.

For functional filtering, see section 27.5.

### 27.2.1 Filter Variants on Custom Criteria

The Filter Variants on Custom Criteria tool can be used to identify and extract variants that fulfill certain criteria. This tool provides the exact same functionality than the one offered by filtering a variant table. There is thus no advantage in using this tool on its own as filtering a table is usually easier, but the tool can be used when building workflows where a filtering step is needed, or when working in batch mode.

To run the Filter Variants on Custom Criteria, go to:

```
Toolbox | Resequencing Analysis | Variant Filtering | Filter Variants on Custom Criteria
```

In the first step, select a variant track as input and click Next.

In the Filter criteria dialog, specify a variant track that contains at least all the criteria you want to filter the first variant track on by using the browse icon. Once specified, click on the Load Annotations button to create the drop down menu available in the filter field below. Note that in this context, we call this track a guidance track because it will define what are the filter criteria available; in the dialog, Load Annotations will transform every column headers of the guidance variant track in a filtering criteria. Please note, that when you create filter criteria with a guiding variant track, you can only filter on annotations that are present in the variant tracks that you would like to filter.

An example of filter criteria is shown in figure 27.24. In this example, we filter away all variants that are not found on chromosome 1 and that are not homozygous. As a result you will only keep the variants that are homozygous and found on chromosome 1. The bottom filter field on the figure shows the various other filter criteria available from the guidance variant track.

The output from the Filter Variants on Custom Criteria tool is a variant track (and table) that contains only the variants that fulfill the specified filter criteria.

### 27.2.2 Filter against Known Variants

The Filter against Known Variants tool filters experimental variants based on a known variants track to remove common variants.

Any variant track can be used as the "known variants track". It may either be produced by the
CHAPTER 27. RESEQUENCING

Figure 27.24: Create filter criteria to extract the variants of interest. In this example we will extract the homozygous variants found on chromosome 1.

CLC Genomics Workbench, imported or downloaded from variant database resources like dbSNP, 1000 genomes, HapMap etc. (see section 6.2 and section 8.1).

To get started, go to:

Toolbox | Resequencing Analysis | Variant Filtering | Filter against Known Variants

This opens a dialog where you can select a variant track with experimental data that should be filtered.

Clicking Next will display the dialog shown in figure 27.25

Select one or more tracks of known variants to compare against. The tool will then compare each of the variants provided in the input track with the variants in the track of known variants. The output will be a variant track where the remaining variants will depend on the mode of filtering chosen:

**Keep variants with exact match found in the track of known variants** This will filter away all variants that are not found in the track of known variants. This mode can be useful for filtering against tracks with known disease-causing mutations, where the result will only include the variants that match the known mutations. The criteria for matching are simple: the variant position and allele both have to be identical in the input and the known variants track (however, note the extra option for joining adjacent SNVs and MNVs described below).
For each variant found, the result track will include information from the known variant. Please note that the exact match criterion can be too stringent, since the database variants need to be reported in the exact same way as in the sample. Some databases report adjacent indels and SNVs separately, even if they would be called as one replacement using the variant detection of CLC Genomics Workbench. In this case, we recommend using the overlap option instead and manually interpret the variants found.

**Keep variants with overlap found in the track of known variants** The first mode is based on exact matching of the variants. This means that if the allele is reported differently in the set of known variants, it will not be identified as a known variant. This is typically not the case with isolated SNVs, but for more complex variants it can be a problem. Instead of requiring a strict match, this mode will keep variants that overlap with a variant in the set of known variants. The result will therefore also include all variants that have an exact match in the track of known variants. This is thus a more conservative approach and will allow you to inspect the annotations on the variants instead of removing them when they do not match. For each variant, the result track will include information about overlapping or strictly matched variants to allow for more detailed exploration.

**Keep variants with no exact match found in the track of known variants** This mode can be used for filtering away common variants if they are not of interest. For example, you can download a variant track from 1000 genomes or dbSNP and use that for filtering away common variants. This mode is based on exact match.

Since many databases do not report a succession of SNVs as one MNV, it is not possible to directly compare variants called with CLC Genomics Workbench with these databases. In order to support filtering against these databases anyway, the option to Join adjacent SNVs and MNVs can be enabled. This means that an MNV in the experimental data will get an exact match, if a set of SNVs and MNVs in the database can be combined to provide the same allele.

**Note!** This assumes that SNVs and MNVs in the track of known variants represent the same allele, although there is no evidence for this in the track of known variants.

This tool will create a new track where common variants have been removed. The annotations that are left are marked in three different ways:

**Exact match** This means that the variant position and allele both have to be identical in the input and the known variants track (however, note the extra option for joining adjacent SNVs and MNVs described below).

**Partial MNV match** This applies to MNVs which can be annotated with partial matches if an SNV or a shorter MNV in the database has an allele sequence that is contained in the allele sequence of the annotated MNV.

**Overlap** This will report if the known variant track has an overlapping variant.

### 27.2.3 Remove Marginal Variants

Variant calling is always a balance between sensitivity and specificity. To get rid of potential false positive variants, you can use this tool on a variant track to remove some of the variant calls, which are supported by only low quality bases, have low frequency or a skewed forward-reverse
reads balance. In this way, you can try different strategies for filtering without re-running the variant detection.

**Toolbox | Resequencing Analysis | Variant Filtering | Remove Marginal Variants**

This opens a dialog where you can select a variant track with experimental data that should be filtered.

Click **Next** to set the filtering thresholds as shown in figure 27.26.

![Filter Marginal Variant Calls](image)

**Figure 27.26: Specifying thresholds for filtering.**

The following thresholds can be specified. All alleles except the reference allele are investigated separately, but in order to remove a variant, all non-reference alleles have to fulfill the requirements.

**Variant frequency** The frequency filter will remove all variants having alleles with a frequency (number of reads supporting the allele/number of all reads) lower than the given threshold.

**Forward/reverse balance** The forward/reverse balance filter will remove all variants having alleles with a forward/reverse balance of less than the given threshold.

**Average base quality** The average base quality filter will remove all variants having alleles with an average base quality of less than the given threshold.

If several thresholds are applied, just one needs to be fulfilled to discard the allele. For more information about how these values are calculated, please refer to section 26.9.1.

The result is a new track where all variants (or at least one non-reference allele of the variant) fulfill the criteria.

### 27.2.4 Remove Variants Present in Control Reads

Running the variant detection tool on a case and control sample separately and filtering away variants found in the control data set does not always give a satisfactory result as many variants in the control sample have not been called. This is often due to lack of read coverage in the corresponding regions or too stringent parameter settings. Therefore, instead of calling variants in the control sample, the Remove Variants Present in Control Reads tool can be used to remove variants found in both samples from the set of candidate variants identified in the case sample.
The variant track from the case sample must be used as input. When clicking Next, you are asked to supply the number of reads in the control data set that should support the variant allele in order to include it as a match (see figure 27.27). All the variants where at least this number of control reads show the particular allele will be filtered away in the result track.

Please note that variants, which have no coverage in the mapped control reads will be reported too. You can identify them by looking for a 0 value in the column ‘Control coverage’.

The following annotations will be added to each variant not found in the control data set:

**Control count** For each allele the number of reads supporting the allele.

**Control coverage** Read coverage in the control dataset for the position in which the allele has been identified in the case dataset.

**Control frequency** Percentage of reads supporting the allele in the control sample.

![Figure 27.27: The control reads data set.](image)

The filter option can be used to set a threshold for which variants should be kept. In the dialog shown in figure 27.27 the threshold is set at two. This means that if a variant is found in one or less of the control reads, it will be kept.

### 27.2.5 Remove Reference Variants

The variant tracks produced by the variant detection tools of CLC Genomics Workbench include reference alleles complementing a non-reference allele (i.e. a heterozygous variant where only one allele is different from the reference). In some situations, this information is not necessary, and these reference allele variants can be filtered away.

This opens a dialog where you can select a variant track that should be filtered. Clicking Next and Finish to create a new track without the reference variants.

### 27.2.6 Remove Orphan Reference Variants

This tool removes orphan variants from a variant track. Orphan variants are described as lacking a variant allele, i.e., a corresponding non-reference variant with exactly the same start and end
positions.

To start the tool, go to:

Toolbox | Resequencing Analysis | Variant Filtering | Remove Orphan Reference Variants

In the first dialog, select the variant track from which you would like to remove orphan variants, and click Next to decide whether to Save or Open the resulting variant track.

**27.3 Variant annotation**

Comparison with known variants from variant databases is a key concept when working with resequencing data. The CLC Genomics Workbench provides tools for annotating your experimental variants with information from known variants (e.g. adding information about phenotypes like cancer associated with a certain variant allele).

For functional annotation, see section 27.5.

**27.3.1 Annotate from Known Variants**

To run the Annotate from known variants tool, go to:

Toolbox | Resequencing Analysis | Variant Annotation | Annotate from Known Variants

This tool will create a new track with all the experimental variants including added information about overlapping variants found in the track of known variants. The annotations are marked in three different ways:

- **Exact match** This means that the variant position and allele both have to be identical in the input and the known variants track (however, note the extra option for joining adjacent SNVs and MNVs described below).

- **Partial MNV match** This applies to MNVs which can be annotated with partial matches if an SNV or a shorter MNV in the database has an allele sequence that is contained in the allele sequence of the annotated MNV.

- **Overlap** This will report if the known variant track has an overlapping variant.

For exact matches, all the information about the variant from the known variants track is transferred to the annotated variant. For partial matches and overlaps, the information from the known variants are not transferred.

**27.3.2 Remove Information from Variants**

This tool removes a reference allele variants that lack a variant allele.

To start the tool, go to:

Toolbox | Resequencing Analysis | Variant Annotation | Remove Information from Variants
In the first dialog, select a variant track (figure 27.28). To process several variant tracks at once, check the batch box. In this case, the next dialog will be the batch overview.

In the next dialog, click on the button Load Annotations to fill the Annotations field underneath as seen in figure 27.29. The content of the Annotations list depends on the annotations present in the track selected as input (and when batching, only in the first track selected). Choose with the radio button whether you want to remove or keep annotations, and select the annotations you wish to remove/keep - depending on what is easiest for your purpose. By clicking on the button Simple View, you can get the list of selected annotations only for verification before clicking Next.

The result of the tool is, for each input file, a similar track containing only the annotations that were chosen to be kept.

27.3.3 Annotate with Conservation Score

The possible functional consequence of a variant can be interrogated by comparing to a conservation score that tells how conserved this particular position is among a set of different species. The underlying line of thought is that conserved bases are functionally important - otherwise they would have been mutated during evolution. If a variant is found at a position that is otherwise well conserved, it is an indication that the variant is functionally important. Of course this is only a prediction, as non-conserved regions could have functional roles too.
Conservation scores can be computed by several tools e.g. PhyloP and PhastCons and can be downloaded as pre-computed scores from an whole genome alignment of different species from different sources. See how to find and import tracks with conservation scores in section 6.2.

**Toolbox | Resequencing Analysis | Variant Annotation | Annotate with Conservation Scores**

Select the variant track as input and when you click Next you will need to provide the track with conservation scores (see figure 27.30).

![Figure 27.30: The conservation score track.](image)

In the resulting track, all the variants will have quality scores annotated, and this can be used for sorting and filtering the track (see section 23.1.2).

### 27.3.4 Annotate with Exon Numbers

**Toolbox | Resequencing Analysis | Variant Annotation | Annotate with Exon Numbers**

Given a track with mRNA annotations, a new track will be created in which variants are annotated with the numbering of the corresponding exon with numbered exons based on the transcript annotations in the input track (see an example of a result in figure 27.31).

![Figure 27.31: A variant found in the second exon out of three in total.](image)

When there are multiple isoforms, a comma-separated list of the exon numbers is given.
27.3.5 Annotate with Flanking Sequence

In some situations, it is useful to see a variant in the context of the bases of the reference sequence. This information can be added using the Annotate with Flanking Sequence tool:

Toolbox | Resequencing Analysis | Variant Annotation | Annotate with Flanking Sequence

This opens a dialog where you can select a variant track to be annotated.

Clicking Next will display the dialog shown in figure 27.32.

![Figure 27.32: Specifying a reference sequence and the amount of flanking bases to include.](image)

Select a sequence track that should be used for adding the flanking sequence, and specify how large the flanking region should be.

The result will be a new track with an additional column for the flanking sequence formatted like this: CGGCT[T]AGTCC with the base in square brackets being the variant allele.

27.4 Variants Comparison

In the toolbox, the folder Variants Comparison contains tools that can be used to compare experimental variants. The tool Identify Shared Variants is similar to the Filter against Known Variants found in the Variant Filtering folder. The main difference is how the tools are used. The Filter against Known Variants should be used when comparing experimental variants with variant databases, and the Identify Shared Variants when comparing experimental variants with other experimental variants.

27.4.1 Identify Shared Variants

This tool should be used if you are interested in finding common (frequent) variants in a group of samples. For example one use case could be that you have 50 unrelated individuals with the same disease and would like to identify variants that are present in at least 70% of all individuals. It can also be used to do an overall comparison between samples (a frequency threshold of 0% will report all alleles).

Toolbox | Resequencing Analysis | Variants Comparison | Identify Shared Variants

This opens a dialog where you can select the variant tracks from the samples in the group. Clicking Next will display the dialog shown in figure 27.33.
The **Frequency threshold** is the percentage of samples that have this variant. Setting it to 70% means that at least 70% of the samples selected as input have to contain a given variant for it to be reported in the output.

The output of the analysis is a track with all the variants that passed the frequency thresholds and with additional reporting of:

- **Sample count** The number of samples that have the variant
- **Total number of samples** The total number of samples (this will be identical for all variants).
- **Sample frequency** This is the same frequency that is also used as a threshold (see figure 27.33).
- **Origin tracks** A comma-separated list of the name of the tracks that contain the variant.

Note that this tool can be used for merging all variants from a number of variant tracks into one track by setting the frequency threshold to 0.

### 27.4.2 Identify Enriched Variants in Case vs Control Samples

This tool should be used if you have a case-control study. This could be individuals with a disease (case) and healthy individuals (control). The Identify enriched Variants in Case vs Control Samples tool will identify variants that are significantly more common in the case samples than in the control samples. The Fisher exact test is applied on the number of occurrences of each allele of each variant in the case and the control data set. The alleles from each variant are considered separately, i.e. for an SNV with two alleles; a Fisher Exact test will be applied to each of the two. The test will also check whether an SNV in the case group is part of an MNV in the control group. Those with a low p-value are potential candidates for variants playing a role in the disease/phenotype. Please note that a low p-value can only be reached if the number of samples in the data set is high.

In the first step of the dialog, you select the case variant tracks (figure 27.34). Clicking **Next** shows the dialog in figure 27.35.

At the top, select the variant tracks from the control group. Furthermore, you must set a threshold for the p-value (default is 0.05); only variants having a p-value below this threshold will be reported. You can choose whether the threshold p-value refers to a corrected value for multiple tests (either Bonferroni Correction, or False Discovery Rate (FDR)), or an uncorrected p-value. A
variant table is created as output (see figure 27.36), reporting only those variants with p-values lower than the threshold. All corrected and uncorrected p-values are shown here, so alternatively, variants with non-significant p-values can also be filtered out or more stringent thresholds can be applied at this stage, using the manual filtering options.

There are many other columns displaying information about the variants in the output table, such as the type, sequence, and length of the variant, its frequency and read count in case and control samples, and its overall zygosity. The zygosity information refers to all of the case samples; a label of ‘homozygous’ means the variant is homozygous in all case samples, a label of ‘heterozygous’ means the variant is heterozygous in all case samples, whereas a label of ‘unknown’ means it is heterozygous in some, and homozygous in others.

**Overlapping variants:** If two different types of variants occur in the same location, these are reported separately in the output table. This is particularly important, where SNPs occur in the same position as an MNV. Usually, multiple SNVs occurring alongside each other would simply be reported as one MNV, but if one SNV of the MNV is found in additional case samples by itself, it will be reported separately. For example, if an MNV of AAT -> GCA at position 1 occurs in five of the case samples, and the SNV at position 1 of A -> G, occurs in an additional 3 samples (so 8 samples in total), the output table will list the MNV and SNV information separately (however, the
SNV will be shown as being present in only 3 samples, as this is the number in which it appears ‘alone’).

The test will also check whether an SNV in the case group is part of an MNV in the control group.

### 27.4.3 Trio Analysis

This tool should be used if you have a trio study with one child and its parents. It should be mainly used for investigating differences in the child in comparison to its parents.

To start the Trio analysis:

**Toolbox | Resequencing Analysis | Variants Comparison | Trio Analysis**

In the first step of the dialog, select the variant track of the child. Clicking **Next** shows the dialog in figure 27.37.

![Figure 27.37: Selecting variant tracks of the parents.](image)

Click on the folder (_folder) to select the two variant tracks for the mother and the father. In case you have a human TRIO, please specify if the child is male or female and how the X, Y chromosomes as well as the mitochondrion are named in the genome track. These parameters are important in order to apply specific inheritance rules to these chromosomes.

Click **Next** and **Finish**.

The output is a variant track showing all variants detected in the child. For each variant in the child, it is reported whether the variant is inherited from the father, mother, both, either or is a de novo mutation. This information can be found in the tooltip for each variant or by switching to the table view (see the column labeled "Inheritance") (figure 27.38).

In cases where both parents are heterozygous with respect to a variant allele, and the child has the same phenotype as the parents, it is unclear which allele was inherited from which parent. Such mutations are described as ‘Inherited from either parent’.

In cases where both parents are homozygous with respect to a variant allele, and the child has the same phenotype as the parents, it is also unclear which allele was inherited from which parent. Such mutations are described as ’Inherited from both parents’.
In cases where both parents are heterozygous and the child homozygous for the variant, the child has inherited a variant from both parents. In such cases the tool will also check for a potential recessive mutation. Recessive mutations are present in a heterozygous state in each of the parents, but are homozygous in the child. To investigate potential disease relevant variants, recessive variants and de novo variants are the most interesting (in case the parents are not affected). The tool will also add information about the genotype (homozygote or heterozygote) in all samples.

For humans, special rules apply for chromosome X (in male children) and chromosome Y, as well as the mitochondrion, as these are haploid and always inherited from the same parent. Heterozygous variants in the child that do not follow mendelian inheritance patterns will be marked in the result.

Her is an example where the trio analysis is performed with a boy:

The boy has a position on the Y chromosome that is heterozygous for C/T. The heterozygous C is not present in neither the mother or father, but the T is present in the father. In this case the inheritance result for the T variant will be: 'Inherited from the father', and for the C variant ‘de novo’. However, both variants will also be marked with 'Yes' in the column 'Mendelian inheritance problem' because of this aberrant situation. In case the child is female, all variants on the Y chromosome will be marked in the same way.

The following annotations will be added to the resulting child track:

**Zygosity** Zygosity in the child as reported from the variant detection tool. Can be either homozygote or heterozygote.
**Zygosity (Name of parent track 1)** Zygosity in the corresponding parent (e.g. father) as reported from the variant detection tool. Can be either homozygote or heterozygote.

**Allele variant (Name of parent track 1)** Alleles called in the corresponding parent (e.g. father).

**Zygosity (Name of parent track 2)** Zygosity in the corresponding parent (e.g. mother) as reported from the variant detection tool. Can be either homozygote or heterozygote.

**Allele variant (Name of parent track 2)** Alleles called in the corresponding parent (e.g. mother).

**Inheritance** Inheritance status. Can be one of the following values, or a combination of these: 'De novo', 'Recessive', 'Inherited from both', 'Inherited from either', 'Inherited from (Name of parent track)'. For example, a proband homozygous for a variant that only one parent (the mother in this case) presents will result in an inheritance described as "De novo, inherited from mother".

**Mendelian inheritance problem** Variants not following the mendelian inheritance pattern are marked here with 'Yes'.

**Note!** If the variant at this position cannot be found in either of the parents, the zygosity status of the parent where the variant has not been found is unknown, and the allele variant column will be left empty.

### 27.5 Functional consequences

The tools for working with functional consequences all take a variant track as input and will predict or classify the functional impact of the variant.

#### 27.5.1 Amino Acid Changes

This tool annotates variants with amino acid changes and creates a track for visual inspection of the amino acid changes. It takes a variant track as input and also requires a track with coding regions and a reference sequence.

To add information about amino acid changes to a variant track:

**Toolbox** | **Resequencing Analysis** | **Functional Consequences** | **Amino Acid Changes**

If you are connected to a server, the first wizard step will ask you where you would like to run the analysis. Next, you must provide the variant track to be annotated with amino acid changes (see figure 27.39).

Click on the button labeled **Next** to go to the next wizard step (figure 27.40).

In this step you get the following options:

- **Select CDS track.** The CDS track is used to determine the reading frame and exon location to be used for translation. If you do not already have CDS, mRNA, and sequence tracks in the Workbench, you can download it with the Reference Data Manager found in the upper right corner of the Workbench.
Figure 27.39: The Amino Acid Changes annotation tool takes variant tracks as input.

Figure 27.40: Select CDS, mRNA, and sequence track and choose whether or not you would like to filter away synonymous variants.

- **Select mRNA track** (optional). The mRNA track is used to determine whether the variant is inside or outside the region covered by the transcript. Without an mRNA track, variants found outside the CDS region will not be annotated. When specifying an mRNA track, the tool will annotate variants that are located in the mRNA, but also outside the region covering the coding sequence in cases where such variants have been detected.

- **Use transcript priorities**: Check this option if you have provided an mRNA track that includes a "Priority" column, i.e., an integer value where "1" is higher priority than "2". Transcripts without any priority are ignored; when adding c. and p. annotations, only the annotation from the highest priority transcript intersecting with the variant will be added. In cases where there are several "priority 1" transcripts, if two genes overlap a variant, only the highest priority transcript(s) will be reported, and this might be from just one of the genes. Note that tracks with priorities transcripts can be generated by modifying a gtf/gff file by adding a "Priority" column.

- **Select sequence track**.
- **Variant location.** In VCF standard, variants with ambiguous positions are left-aligned, while HGVS standard places ambiguous variants most 3’ relative to the transcript annotation. Checking the option "Move variants from VCF location to HGVS location" will output a track where ambiguous variants will be located following the HGVS standard, even when it moves the variant across intron/exon boundaries and flanking regions. This option is recommended when comparing variants with databases following the HGVS standard, and in particular when working with downstream software such as Ingenuity Variant Analysis and QCI Interpret. This option does not affect the HGVS annotations added by the tool.

- **Flanking.** It is possible to add c. annotations (HGVS DNA-level) to upstream and downstream flanking positions if they are within a certain distance from the transcript boundaries. The distance can be configured but the default distances are set to 5 kb upstream and 3 kb downstream.

- **Filtering and annotation.**
  - The "Filter synonymous variants" option allows you to filter away synonymous variants that does not cause any change to the encoded amino acid.
  - By default, the tool will filter out CDS regions that have no variants. You can choose to include them in your amino acid annotation track by deselecting the "Filter CDs regions with no variants" option.
  - The genetic code is the code that is used for amino acid translation (see http://www.ncbi.nlm.nih.gov/Taxonomy/Utils/wprintgc.cgi). The default option is "1 standard", the vertebrate standard code. If relevant, you can use the drop-down list to change to the genetic code that applies to your organism.

Click on the button labeled **Next**, choose whether you would like to open or save the results and click on the button labeled **Finish**.

Two types of outputs are generated:

1. **A variant track** that has been annotated with the amino acid changes. The added information can be accessed via the tooltips in the variant track or in the extra columns that have been added to the variant table. The extra columns provide information about the amino acid changes (see http://www.ncbi.nlm.nih.gov/Taxonomy/Utils/wprintgc.cgi). The variant track opens in track view and the table view can be accessed by clicking on the table icon found in the lower left corner of the **View Area**.

2. **An amino acid track** that displays a graphical presentation of the amino acid changes. The track is based on the CDS track and in addition to the amino acid sequence of the coding sequence, all amino acids that have been affected by variants are shown as individual amino acids below the amino acid track. Changes causing a frameshift are symbolized with two arrow heads, and variants causing premature stop are marked with an asterisk. An example is shown in figure 27.41.

For each variant in the input track, the following information is added:

- **Coding region change.** This describes the relative position on the coding DNA level, using the nomenclature proposed at http://varnomen.hgvs.org/. Variants inside exons and in the untranslated regions of the transcript will also be annotated with the distance to
Figure 27.41: The variant track and the amino acid track is here presented together with the reference sequence and the mRNA and CDS tracks. An insertion (purple arrow) has caused a frameshift (red arrow) that has changed an alanine to a stop codon (blue arrow).

the nearest exon. E.g. “c.-4A>C” describes a SNV four bases upstream of the start codon, while “c.*4A>C” describes a SNV four bases downstream of the stop codon.

- **Amino acid change.** This describes the change on the protein level. For example, single amino-acid changes caused by SNVs are listed as p.Gly261Cys, denoting that in the protein sequence (hence the “p.”) the Glycine at position 261 is changed into Cysteine. Frame-shifts caused by nucleotide insertions and deletions are listed with the extension fs, for example p.Pro244fs denoting a frameshift at position 244 coding for Proline. For further details about HGVS nomenclature as relates to proteins, please refer to [http://varnomen.hgvs.org/recommendations/protein/](http://varnomen.hgvs.org/recommendations/protein/).

- **Coding region change in longest transcript.** When there are many transcript variants for a gene, the coding region change for all transcripts are listed in the “Coding region change” column. For quick reference, the longest transcript is often used, and there is a special column only listing the coding region change for the longest transcript.

- **Amino acid change in longest transcript.** This is similar to the above, just on the protein level.

- **Other variants within codon.** If there are other variants within the same codon, this column will have a "Yes". In this case, it should be manually investigated whether the two variants are linked by reads.

- **Non-synonymous.** Will have a "Yes" if the variant is non-synonymous at the protein level for any transcript. If the filter “Filter synonymous” was applied, this column will only contain
entries labeled "Yes". A hyphen, ",-", indicates the variant was present outside of a coding region.

An example of the output is given in figure 27.42.

Figure 27.42: The resulting amino acid changes in track and table views. When the variant table has been opened by double-clicking on the text found in the left side of the View Area, the variant table and the variant track are linked. When clicking on an entry in the table, this position will be brought into focus in the variant track.

The top track view displays a track list with the reference sequence, mRNA, CDS, variant, and amino acid tracks. The lower table view is the variant table that has been opened from the track list by double-clicking on the variant track name found in the left-hand side of the View Area. When opening the variant table in split view from the track list, the table and the variant track are linked.

An example illustrating a situation where different variants affect the same codon is shown in figure 27.43.

In this example three single nucleotide deletions are shown along with the resulting amino acid changes based on scenarios where only one deletion is present at the time. The first affected amino acid is shown for each of the three deletions. As the first deletion affect the encoded amino acid, this amino acid change is shown with a four nucleotide long arrow (that includes
Amino acids encoded from codons that potentially could have been affected by more than one variant are marked with a hash symbol (#) as the graphically presented amino acid changes always only include a single variant (a SNV, MNV, insertion, or deletion). Shown here are three different variants, present only one at the time, and the consequences of the three individual deletions. In cases where the deletion is found in a codon that is affected with an amino acid change, the arrow also include the deletion (situation 1) in the two other scenarios, the codon containing the deletion is changed to a codon that encodes the same amino acid, and the effect is therefore not seen until in the subsequent amino acid.

The other two deletions do not affect the encoded amino acid as the frameshift was "synonymous" at the position encoded by the codon where the deletion was introduced. The effect is first seen at the next amino acid position (763 and 764, respectively), which does not contain a deletion, and therefore is illustrated with a three nucleotide long arrow.

The hash symbol (#) on the changed amino acids symbolize that more than one variant can be present in the region encoding this specific amino acid. The simultaneous presence of multiple variants within the same codon is not predicted by the amino acid changes tool. Manual inspection of the reads is required to be able to detect multiple variants within one codon.

The amino acid track

The colors of the amino acids in the amino acid track can be changed in the Side Panel under Track layout and "Amino acids track" (see figure 27.44).

Four different color schemes are available under "Amino acid colors":

- **Gray** All amino acids are shown in gray.
- **Group** Colors the amino acids in groups by the following properties:
  - **Purple** neutral, polar
  - **Turquoise** neutral, nonpolar
Figure 27.44: The colors of the amino acids can be changed in the Side Panel under "Amino acids track".

- **Orange** acidic, polar
- **Blue** basic, polar
- **Bright green** other (functional properties)

- **Polarity** Colors the amino acids according to the following categories:
  - **Green** neutral, polar
  - **Black** neutral, nonpolar
  - **Red** acidic, polar
  - **Blue** basic, polar

- **Rasmol** Colors the amino acids according to the Rasmol color scheme (see [http://www.openrasmol.org/doc/rasmol.html](http://www.openrasmol.org/doc/rasmol.html)).

### 27.5.2 Predict Splice Site Effect

This tool will analyze a variant track to determine whether the variants fall within potential splice sites. First select your variant track (figure 27.45) followed by a transcript track (see figure 27.46). As part of the dialog you can choose to exclude all variants that do not fall within a splice site.

If a variant falls within two base pairs of an intron-exon boundary, it will be annotated as a possible splice site disruption (see figure 27.47).

### 27.5.3 GO Enrichment Analysis

This tool can be used to investigate candidate variants, or better their corresponding altered genes for a common functional role. For example if you would like to know what is interesting
in the zebu cattle in comparison to bison and taurine cattle, you can use this tool. For that approach, first filter all found variants in zebu for zebu-specific variants and afterwards run the GO enrichment test for biological process to see that more variants than expected are in immune response genes. These can then be further investigated.

You will need a GO association file to run this tool. Such a file includes gene names and associated Gene Ontology terms and can be downloaded that from the Gene Ontology web site for various species (http://www.geneontology.org/GO.downloads.annotations.shtml). Download the GO Annotations of the relevant species by clicking on the *.gz link in the table (see figure 27.48). Import the downloaded annotations into the workbench using **Import | Standard Import**.

You will also need a Gene track for the relevant species (learn more about gene tracks in section 23.1).
To run the GO Enrichment analysis, go to the toolbox:

**Toolbox | Resequencing Analysis | Functional Consequences | GO Enrichment Analysis**

First, select the variant track containing the variants to analyse. You then have to specify both the annotation association file and the gene track. Finally, choose which ontology (cellular component, biological process or molecular function) you would like to test for (see figure 27.49).

The analysis starts by associating all of the variants from the input variant file with genes in the gene track, based on overlap with the gene annotations.

Next, the Workbench tries to match gene names from the gene (annotation) track with the gene names in the GO association file. Note that the same gene name definition should be used in both files.

Finally, an hypergeometric test is used to identify over-represented GO terms by testing whether some of the GO terms are over-represented in a given gene set, compared to a randomly selected set of genes.

The result is a table with GO terms and the calculated p-value for the candidate variants, as well as a new variant file with annotated GO terms and the corresponding p-value (see figure 27.50).

The p-value is the probability of obtaining a test statistic at least as extreme as the one that was actually observed, or in other words how significant (trustworthy) a result is. In case of a small
p-value the probability of achieving the same result by chance with the same test statistic is very small.

![Figure 27.50: The results of the analysis.](image)

In addition to the p-values, the table lists for each GO term the number and names of the genes that matched, and the number and names of the matched genes that contain at least one variant.

**27.5.4 Download 3D Protein Structure Database**

This tool downloads the 3D Protein Structure Database from a public accessible HTTP location hosted by QIAGEN Aarhus.

The database contains a curated set of sequences with known 3D structures, which are obtained from the Protein Data Bank (http://www.wwpdb.org) [Berman et al., 2003]. The information stored in the database (e.g., protein sequence, X-ray resolution) is used to identify suitable structural templates when using the **Link Variants to 3D Protein Structure** tool.

To download the database, select:

```
Toolbox | Resequencing Analysis | Functional Consequences | Download 3D Protein Structure Database
```

If you are connected to a server, you will first be asked about whether you want to download the data locally or on a server. In the next wizard step you are asked to select the download location (see figure 27.51).

![Figure 27.51: Select the download location.](image)

The downloaded database will be installed in the same location as local BLAST databases (e.g. `<username>/CLCdatabases`) or at a server location if the tool was executed on a CLC Server. From the wizard it is possible to select alternative locations if more than one location is available.
When new databases are released, a new version of the database can be downloaded by invoking the tool again (the existing database will be replaced).

If needed, the **Manage BLAST Databases** tool can be used to inspect or delete the database (the database is listed with the name ‘ProteinStructureSequences’). You can find the tool here:

![BLAST](BLAST) | Manage BLAST Databases

### 27.5.5 Link Variants to 3D Protein Structure

This tool makes it possible to visualize variant consequences on 3D protein structures. It takes a variant track as input, and produces a new variant track as output, with two additional columns in the table view:

- **Link to 3D protein structure**: If a variant affects the amino acid composition of a protein, and a 3D structure of sufficient homology can be found in the Protein Data Bank (PDB), a link is provided in this column. Via the link, the structure can be downloaded and a 3D model and visualization of the variant consequences on the protein structure will be created.

- **Effect on drug binding site**: If any of the homologous structures found in PDB has a drug or ligand in contact with the amino acid variation, a link is provided in this column. Via the link, a list of drug hits can be inspected. The list has links for creating 3D models and visualizations of the variant-drug interaction.

In section 27.5.5 it is described how to interpret the output in the variant table and how the tool finds appropriate protein structures to use for the visualizations, and in section 27.5.5 and onwards it is described how the 3D models and visualizations are created.

**Note**: Before running the tool, a protein structure sequence database must be downloaded and installed using the **Download 3D Protein Structure Database** tool (see section 27.5.4).

To run the tool, select:

**Toolbox** | Resequencing Analysis | Functional Consequences | Link Variants to 3D Protein Structure

If you are connected to a server, you will first be asked where you want to run the analysis. In the next wizard step you will be asked for an input file. The **Link Variants to 3D Protein Structure** accepts variant tracks as input (see figure 27.52).

Click on the button labeled **Next**. In the next wizard step, you must provide a CDS track and the reference sequence track (figure 27.53).

If you have not already downloaded a CDS and a reference sequence track, this can be done using the Reference Data Manager (see section 8.1).

Click on the button labeled **Next**, choose where you would like to save the data, and click on the button labeled **Finish**.
Select the variant track holding the variants that you would like to visualize on 3D protein structures.

Select CDS and reference sequence.

As output, the tool produces a new variant track, with two additional columns in the table view ('Link to 3D protein structure' and 'Effect on drug binding site' - figure 27.54). The default output view is the variant track. To shift to table view, click on the table icon found in the lower left corner of the View Area.

The variant table output

For each variant in the input, the Link Variants to 3D Protein Structure tool does the following, to prepare output for the "Link to 3D protein structure" and "Effect on drug binding site" columns in the output variant track:

1. Evaluate if the variant is found inside a CDS region. Otherwise the following is returned for the variant: **outside CDS regions**.
2. If the variant is in a CDS region, translate the reference sequence of the impacted gene into an amino acid sequence and evaluate if the variant can be expected to have an effect on protein structure that can be visualized. Overlapping genes (common in prokaryotic genomes) with different reading frames may cover a given variation, in which case multiple protein sequences will be considered.

For variants that cannot be visualized, the gene name and one of the reasons given below will be listed in the output table:

- **(nonsense)** - the variant would result in a stop codon being introduced in the protein sequence.
- **(synonymous)** - the variant would not change the amino acid.
- **(frame shift)** - the variant would introduce a frame shift.

3. BLAST the translated amino acid sequence (the query sequence) against the protein structure sequence database (see section 27.5.4) to identify structural candidates. Note that if multiple splicing variants exist, the protein structure search is based on the longest splicing variant. BLAST hits with E-value > 0.0001 are rejected and a maximum of 2500 BLAST hits are retrieved. If no hits are obtained, the gene name and the message **(no PDB hits)** are listed.

4. For each BLAST hit, check if the variant is covered by the structure. For a variant resulting in one amino acid being replaced by another, the affected amino acid position should be present on the structure. For a variant resulting in amino acid insertions or deletions, the amino acids on both sides of the insertion/deletion must be present on the structure.

5. For the BLAST hits covering the variant, rank the structures considering both structure quality and homology (see section 27.5.5).

6. Add the gene name and the description of the amino acid change to the "Link variant to 3D protein structure" column in the output variant track. A link on the description gives access to a 3D view of the variant effect using the best ranked protein structure from point 5 (see section 27.5.5). Note that the amino acid numbering is based on the longest CDS annotation found.

7. Extract all BLAST hits from point 5, where the affected amino acid(s) are in contact with a drug or ligand in the PDB file (heavy atoms within 5 Å). If no structures with variant-drug interaction are found, the following is returned to the "Effect on drug binding site" column: **No drug hits** together with the gene name and the description of the amino acid change. If structures with variant-drug interaction are found, the number of different drugs or ligands encountered are written to the "Effect on drug binding site" column as **X drug hits**. From a link on "X drug hits", a list describing the drug hits in more detail can be opened. The list also has a link for each drug, to create a 3D model and visualization of the variant-drug interaction section 27.5.5.

**Create 3D visualization of variant**

Clicking a link provided in the ‘Link to 3D Protein Structure’ column will show a menu with three options:

- 'Download and Show Structure’ will open a 3D view visualizing the consequences of the variant on a protein structure (figure 27.54).
'Download and Show All Variants (x) on Structure' will open a 3D view visualizing the consequences of x variants on the same protein structure (figure 27.55).

Note 1: Only variants shown in the table will be included in the view (e.g. variants filtered out will be ignored).

Note 2: It is not always possible to visualize variants on the same gene together on the same structure, since many structures in the PDB only cover parts of the whole protein.

Note 3: Even though variants may be possible to visualize together, it does not necessarily mean they occur together on the same protein. For example, in diploid cells, heterozygous variants may not.

"Help" gives access to this documentation.

Figure 27.55: Generated 3D view of variant. The reference amino acid is seen in purple and the variant in cyan on top of each other. Only the backbone of protein structures are visualized by default. The modeled protein structure is colored to indicate local model uncertainty - red for flexible and uncertain parts of the structure model and blue for very well defined and accurate parts of the structure model. Other molecules from the PDB file are colored orange or yellow.

The "Download and Show...." options will do the following:

1. **Download and import** the PDB file containing the protein structure for the variant (found by the 'Link Variants to 3D Protein Structure' tool - section 27.5.5).

2. **Generate biomolecule** involving the modeled chain, if the information is available in the PDB file (see Infobox below).

3. **Create an alignment** between the reference protein sequence for the gene impacted by the variant (the query sequence) and the sequence from the protein structure (the template structure).

4. **Create a model structure for the reference** by mapping it onto the template structure based on the sequence alignment (see section 27.5.5).

5. **Create a model structure with variant(s)** by mapping the protein sequence with the variant consequences onto the reference structure model (see section 27.5.5).
6. **Open a 3D view** (a Molecule Project) with the variant structure model shown in backbone representation. The model is colored by temperature (see figure 27.55), to indicate local model uncertainty (see section 27.5.5). The consequence(s) of the variant(s) are highlighted by showing involved amino acids in ball n’ sticks representation with the reference colored purple and the variant cyan. Other molecules from the PDB file are shown in orange or yellow coloring (figure 27.55).

From the Project Tree in the Side Panel of the Molecule Project, the category 'Atom groups’ contains two entries for each variant shown on the structure - one entry for the reference and one for the variant (figure 27.55). The atom groups contain the visualization of the variant consequence on structure. For variants resulting in amino acid replacements, the affected amino acid is visualized. For variants resulting in amino acid insertions or deletions, the amino acids on each side of the deletion/insertion are visualized.

The template structure is also available from the Proteins category in the Project Tree, but hidden in the initial view. The initial view settings are saved on the Molecule Project as "Initial visualization", and can always be reapplied from the View Settings menu ( bölümü found in the bottom right corner of the Molecule Project (see section 4.6).

**Tip:** Double-click an entry in the Project Tree to zoom the 3D view to the atoms.

You can save the 3D view (Molecule Project) in the Navigation Area for later inspection and analysis. Read more about how to customize visualization of molecules in section 13.3.

**Infobox: Biomolecules in CLC Genomics Workbench**

Protein structures imported from a PDB file show the tertiary structure of proteins, but not necessarily the biologically relevant form (the quaternary structure). Oftentimes, several copies of a protein chain need to arrange in a multi-subunit complex to form a functioning biomolecule. In some PDB files several copies of a biomolecule are present and in others only one chain from a multi-subunit complex is present. In many cases, PDB files have information about how the molecule structures in the file can form biomolecules.

In **CLC Genomics Workbench** variants are therefore shown in a protein structure context representing a functioning biomolecule, if this information is available in the selected template PDB file.

**Visualize drug interaction**

Clicking a link provided in the ‘Drug interaction in protein 3D structure’ column will open a list with information about the drug hits (figure 27.56).

![Figure 27.56](image.png)

**Figure 27.56:** An example of a **drug hit table with information about the drug and with links to 3D visualizations of variant-drug interaction.**

The information available in the drug hit list is the following:
• **PDB hit.** Clicking a link provided in the PDB hit column will show a menu with two options: "Download and Show Structure" and "Help". "Help" gives access to this documentation. The "Download and Show Structure" option does exactly as described in section 27.5.5, except that the final 3D visualization is centered on the drug, and the drug is shown in ball n' sticks representation with atoms colored according to their atom types (figure 27.57).

• **PDB drug name.** (Hidden by default) The identifier used by PDB for the ligand or drug.

• **Drug name.** When possible, a common name for the potential drug is listed here. The name is taken from the corresponding DrugBank entry (if available) or from the PDB header information for the PDB hit.

• **DrugBank info.** If information about the drug or ligand is available in DrugBank (www.drugbank.ca [Law et al., 2014, Wishart et al., 2006]), a weblink to the appropriate site is listed here.

• **E-value.** (Hidden by default) The E-value is a measure of the quality of the match returned from the BLAST search. The closer to zero, the more homologous is the template structure to the query sequence.

• **Organism.** (Hidden by default) The organism for which the PDB structure has been obtained.

• **Description.** The description of the PDB file content, as given in the header of the PBD hit.

![Figure 27.57: 3D visualization of variant-drug interaction. The drug (streptomycin) is in center of the view, and colored according to its atom types. The variant is visualized as in figure 27.55. In this picture, the foreground has been cut away using the clipping plane functionality found in the Visualization tab in the Side Panel, to better see the variant-drug interaction.]

**Protein coloring to visualize local structural uncertainties**

The default coloring scheme for modeled structures in CLC Genomics Workbench is "Color by Temperature". This coloring indicates the uncertainty or disorder of each atom position in the structure.
For crystal structures, the temperature factor (also called the B-factor) is given in the PDB file as a measure of the uncertainty or disorder of each atom position. The temperature factor has the unit Å², and is typically in the range [0, 100].

The temperature color scale ranges from blue (0) over white (50) to red (100) (see section 13.3.1).

For structure models created in $\text{CLC Genomics Workbench}$, the temperature factor assigned to each atom combines three sources of positional uncertainty:

- **PDB Temp.** The atom position uncertainty for the template structure, represented by the temperature factor of the backbone atoms in the template structure.

- **P(alignment)** The probability that the alignment of a residue in the query sequence to a particular position on the structure is correct.

- **Clash?** It is evaluated if atoms in the structure model seem to clash, thereby indicating a problem with the model.

The three aspects are combined to give a temperature value between zero and 100, as illustrated in figure 27.58 and 27.59.

![Figure 27.58: Evaluation of temperature color for backbone atoms in structure models.](image)

![Figure 27.59: Evaluation of temperature color for side chain atoms in structure models.](image)

When holding the mouse over an atom, the Property Viewer in the Side Panel will show various information about the atom. For atoms in structure models, the contributions to the assigned temperature are listed as seen in figure 27.60.
Figure 27.60: Information displayed in the Side Panel Property viewer for a modeled atom.

**Note:** For NMR structures, the temperature factor is set to zero in the PDB file, and the "Color by Temperature" will therefore suggest that the structure is more well determined than is actually the case.

### P(alignment)

Alignment error is one of the largest causes of model inaccuracy, particularly when the model is built from a template sharing low sequence identity (e.g. lower than 60%). Misaligning a single amino acid by one position will cause a ca. 3.5 Å shift of its atoms from their true positions.

The estimate of the probability that two amino acids are correctly aligned, P(alignment), is obtained by averaging over all the possible alignments between two sequences, similar to [Knudsen and Miyamoto, 2003].

This allows local alignment uncertainty to be detected even in similar sequences. For example the position of the D in this alignment:

**Template**

GGACDAEDRSTRSTACE---GG

**Target**

GGACD---RSTRSTACEKLMGG

is uncertain, because an alternative alignment is as likely:

**Template**

GGACDAEDRSTRSTACE---GG

**Target**

GGAC---DRSTRSTACEKLMGG

### Clash?

Clashes are evaluated separately for each atom in a side chain. If the atom is considered to clash, it will be assigned a temperature of 100.

**Note:** Clashes within the modeled protein chain as well as with all other molecules in the downloaded PDB file (except water) are considered.

### Ranking structures

The protein sequence of the gene affected by the variant (the query sequence) is BLASTed against the protein structure sequence database (section 27.5.4).

A *template quality score* is calculated for the available structures found for the query sequence. The purpose of the score is to rank structures considering both their quality and their homology.
to the query sequence.

The five descriptors contributing to the score are:

- E-value
- % Match identity
- % Coverage
- Resolution (of crystal structure)
- Free R-value ($R_{\text{free}}$ of crystal structure)

Each of the five descriptors are scaled to [0,1], based on the linear functions seen in figure 27.62. The five scaled descriptors are combined into the template quality score, weighting them to emphasize homology over structure qualities.

$$\text{Template quality score} = 3 \cdot S_{\text{E-value}} + 3 \cdot S_{\text{Identity}} + 1.5 \cdot S_{\text{Coverage}} + S_{\text{Resolution}} + 0.5 \cdot S_{R_{\text{free}}}$$

**E-value** is a measure of the quality of the match returned from the BLAST search. You can read more about BLAST and E-values in section 12.5.

% **Match identity** is the identity between the query sequence and the BLAST hit in the matched region. It is evaluated as

$$\text{% Match identity} = 100\% \cdot \frac{\text{Identity in BLAST alignment}}{L_B}$$

where $L_B$ is the length of the BLAST alignment of the matched region, as indicated in figure 27.61, and "Identity in BLAST alignment" is the number of identical positions in the matched region.

% **Coverage** indicates how much of the query sequence has been covered by a given BLAST hit (see figure 27.61). It is evaluated as

$$\text{% Coverage} = 100\% \cdot \frac{L_B - L_G}{L_Q}$$

where $L_G$ is the total length of gaps in the BLAST alignment and $L_Q$ is the length of the query sequence.

The **resolution** of a crystal structure is related to the size of structural features that can be resolved from the raw experimental data.

$R_{\text{free}}$ is used to assess possible overmodeling of the experimental data.

Resolution and $R_{\text{free}}$ are only given for crystal structures. NMR structures will therefore usually be ranked lower than crystal structures. Likewise, structures where $R_{\text{free}}$ has not been given will tend to receive a lower rank. This often coincides with structures of older date.
CHAPTER 27. RESEQUENCING

Figure 27.61: Schematic of a query sequence matched to a BLAST hit. $L_Q$ is the length of the query sequence, $L_B$ is the length of the BLAST alignment of the matched region, QG1-3 are gaps in the matched region of the query sequence, HG1-2 are gaps in the matched region of the BLAST hit sequence, $L_G$ is the total length of gaps in the BLAST alignment.

Figure 27.62: From the E-value, % Match identity, % Coverage, Resolution, and Free R-value, the contributions to the "Template quality score" are determined from the linear functions shown in the graphs.

How a model structure is created

A structure model is created by mapping the query sequence onto the template structure based on a sequence alignment (see figure 27.63):

- For identical amino acids (example 1 in figure 27.63) => Copy atom positions from the PDB file. If the side chain is missing atoms in the PDB file, the side chain is rebuilt (section 27.5.5).

- For amino acid changes (example 2 in figure 27.63) => Copy backbone atom positions from the PDB file. Model side chain atom positions to match the query sequence (section...
CHAPTER 27. RESEQUENCING

Figure 27.63: Sequence alignment mapping query sequence (Query CDK5_HUMAN) to the structure with sequence "Template(3QQJ - CYCLIN-DEPENDENT KINASE 2)", producing a structure with sequence "Model(CDK5_HUMAN)". Examples are highlighted: 1. Identical amino acids, 2. Amino acid changes, 3. Amino acids in query sequence not aligned to a position on the template structure, and 4. Amino acids on the template structure, not aligned to query sequence.

27.5.5).

- For amino acids in the query sequence not aligned to a position on the template structure (example 3 in figure 27.63) => No atoms are modeled. The model backbone will have a gap at this position and a "Structure modeling" issue is raised (see section 13.1.4).

- For amino acids on the template structure, not aligned to the query sequence (example 4 in figure 27.63) => The residues are deleted from the structure and a "Structure modeling" issue is raised (see section 13.1.4).

How side chains are modeled

Amino acid side chains tend to assume one of a discrete number of "rotamer" conformations. The rotamers used in CLC Genomics Workbench have been calculated from a non-redundant set of high-resolution crystal structures.

Side chains are modeled using a heat bath Monte Carlo simulated annealing algorithm, similar to the OPUS-Rota method [Lu et al., 2008]. The algorithm consists of approximately 100 cycles of simulation. In a single cycle, rotamers are selected for each side chain with a probability according to their energy. As the simulation proceeds, the selection increasingly favors the rotamers with the lowest energy, and the algorithm converges.

A local minimization of the modeled side chains is then carried out, to reduce unfavorable interactions with the surroundings.

Calculating the energy of a side chain rotamer

The total energy is composed of several terms:

- Statistical potential: This score accounts for interactions between the given side chain and the local backbone, and is estimated from a database of high-resolution crystal structures. It depends only on the rotamer and the local backbone dihedral angles $\phi$ and $\psi$.

- Atom interaction potential: This score is used to evaluate the interaction between a given side chain atom and its surroundings.
• Disulfide potential: Only applies to cysteines. It follows the form used in the RASP program [Miao et al., 2011] and serves to allow disulfide bridges between cysteine residues. It penalizes deviations from ideal disulfide geometry. A distance filter is applied to determine if the disulfide potential should be used, and when it is applied the atom interaction potential between the two sulfur atoms is turned off. Note that disulfide bridges are not formed between separate chains.

**Note:** The atom interaction potential considers interactions within the modeled protein chain as well as with all other molecules in the downloaded PDB file (except water).

**Local minimization of side chain**

After applying a side chain rotamer from the library to the backbone, a local minimization may be carried out for rotations around single bonds in the side chain.

The potential to minimize with respect to bond rotation is composed of the following terms:

• Atom interaction potential: Same as for calculating the energy of a rotamer.

• Disulfide potential: Same as for calculating the energy of a rotamer.

• Harmonic potential: This penalizes small deviations from ideal rotamers according to a harmonic potential. This is motivated by the concept of a rotamer representing a minimum energy state for a residue without external interactions.

Based on an annotated reference genome, the CLC Genomics Workbench supports RNA-Seq Analysis by mapping next-generation sequencing reads and distributing and counting the reads across genes and transcripts. Subsequently, the results can be used for expression analysis. The tools from the RNA-Seq folder automatically account for differences due to sequencing depth, removing the need to normalize input data. The statistical analysis and visualization tools of the RNA-Seq folder make extensive use of the metadata system.

**TMM Normalization**

Since the sequencing depth might differ between samples, a per-sample library size normalization must be performed before samples can be compared. In the case of the tools included in the RNA-Seq folder, this normalization is automatically applied by the tools.

For the RNA-Seq tools that compare samples (PCA for RNA-Seq, Create Heat Map for RNA-Seq, Differential Expression for RNA-Seq and Create Expression Browser), library size normalization is automatically performed using the TMM (trimmed mean of M values) method [Robinson and Oshlack, 2010]. Libraries sizes are then used as part of the per-sample normalization. TMM normalization is the normalization used in edgeR [Robinson et al., 2010].

TMM normalization adjusts library sizes based on the assumption that most genes are not differentially expressed. Therefore, it is important not to make subsets of the count data before doing statistical analysis or visualization, as this can lead to differences being normalized away.

For the expression visualization tools (Create Heat Map and PCA for RNA-Seq) additional filtering and normalization are performed:

- 'log CPM' (Counts per Million) values are calculated for each gene. The CPM calculation uses the effective library sizes as calculated by the TMM normalization.

- After this first normalization, a second one is performed across samples for each gene: the counts for each gene are mean centered, and scaled to unit variance.

- Genes or transcripts with zero expression across all samples or invalid values (NaN or +/- Infinity) are removed.

**Metadata for RNA-Seq**

The statistical analysis and visualization tools of the RNA-Seq folder make extensive use of the metadata system. For example, metadata are required when defining the experimental design in the Differential Expression for RNA-Seq tool, and can be used to add extra layers of insight in the Create Heat Map and PCA for RNA-Seq tools.

To get the most out of these tools we recommend that all input expression tracks have associated metadata, as shown in figure 28.1. For information about how to use and setup metadata, please see section 3.2.

**28.1 RNA-Seq Analysis**

The following describes the overall process of the RNA-Seq analysis when using an annotated eukaryote genome. See section 28.1.1 for more information on other types of reference data.
The RNA-Seq analysis is done in several steps: First, all annotated transcripts are extracted (using an mRNA track). If there are several annotated splice variants, they are all extracted. An example is shown in figure 28.2.

This is a simple gene with three exons and two splice variants. The transcripts are extracted as shown in figure 28.3.

Next, the reads are mapped against all the transcripts, and to the whole genome. For more information about the read mapper, see section 25.1.

From this mapping, the reads are categorized and assigned to the transcripts using the EM estimation algorithm, and expression values for each gene are obtained by summing the transcript counts belonging to the gene.

### 28.1.1 Specifying reads and reference

To start the RNA-Seq analysis, go to:

**Toolbox | RNA-Seq Analysis ( ) | RNA-Seq Analysis ( )**

This opens a dialog where you select the **sequencing reads**. Note that you need to import the
sequencing data into the Workbench before it can be used for analysis. Importing read data is described in section 6.3.

If you have several samples that you wish to analyze independently and compare afterwards, you can run the analysis in batch mode (see section 9.3).

Click **Next** when the sequencing data are listed in the right-hand side of the dialog.

You are now presented with the dialog shown in figure 28.4.

![Figure 28.4: Defining a reference genome for RNA-Seq.](image)

At the top, there are three options concerning how the reference sequences are annotated.

- **Genome annotated with genes and transcripts.** This option should be used when both gene and mRNA annotations are available. When this option is enabled, the EM will distribute the reads over the transcripts. Gene counts are then obtained by summing over the (EM-distributed) transcript counts. The mRNA annotations are used to define how the transcripts are spliced (as shown in figure 28.2). This option should be used for **Eukaryotes** since it is the only option where splicing is taken into account. Note that genes and transcripts are linked by name only (not by position, ID etc).

  When this option is selected, both a **Gene** and an **mRNA** track should be provided in the boxes below. Annotated reference genomes be can obtained in various ways:

  - Directly downloaded as tracks using the Reference Data Manager (see section 8.1).
  - Imported as tracks from fasta and gff/gtf files (see section 6.2)
  - Imported from Genbank or EMBL files and converted to tracks (see section 23.5).
  - Downloaded from Genbank (see section 7.1) and converted to tracks (see section 23.5).

When using this option, Expression values, RPKM and TPM are calculated based on the lengths of the transcripts provided by the mRNA track. If a gene’s transcript annotation is absent from the mRNA track, all values will be set to 0 unless the option "Calculate expression for genes without transcript" is checked in a later dialog.
• **Genome annotated with genes only.** This option should be used for *Prokaryotes* where transcripts are not spliced. When this option is selected, a Gene track should be provided in the box below. The data can be obtained in the same ways as described above. When using this option, Expression values, RPKM and TPM are calculated based on the lengths of the genes provided by the Genes track.

• **One reference sequence per transcript.** This option is suitable for situations where the reference is a list of sequences. Each sequence in the list will be treated as a "transcript" and expression values are calculated for each sequence. This option is most often used if the reference is a product of a *de novo* assembly of RNA-Seq data. It is also a suitable option for references where genes are particularly close to each other or clustered in operon structures (see section 28.1.1). When this option is selected, only the reference sequence should be provided, either as a sequence track or a sequence list. Expression values, RPKM and TPM are calculated based on the lengths of sequences from the sequence track or sequence list.

**Tightly packed genes and genes in operons**  For annotated references containing genes located very close to each other (including operon structures) only reads mapping completely within a gene’s boundaries will be counted towards the expression value for that gene. If any part of a read maps outside a given gene’s boundaries, then it will be considered intergenic and will not be counted towards the expression value. For tightly packed genes, especially in cases where non-coding 5’ regions are not included in the gene annotation, this can be too conservative: if there are short genes, where the read length exceeds the gene length in some cases, then some granularity may be lost. That is, reads mapping to short genes might not be counted at all.

If this situation arises in your data, you can do the following:

- Use the option "One reference per transcript" in the "Select reference" wizard, and input a list of transcript sequences instead of a track. A list of sequences can be generated from a mRNA track (or a gene track for bacteria if no mRNA track is available) using the Extract Annotations tool (see section 32.2).

- In cases where the input reads are paired-end, choose the option "Count paired reads as two" in the Expression level options dialog. This will ensure that each read of the pair is counted towards the expression of the gene with which it overlaps, (by default, paired reads that map to different genes are not counted).

This strategy is equivalent to the option "Map to gene regions only (fast)" option that was available in the workbench released before February 2017.

At the bottom of the dialog you can choose between these two options:

- **Do not use spike-in controls.**

- **Use spike-in controls.** In this case, you can provide a spike-in control file in the field situated at the bottom of the dialog window. Make sure you remember to check the option to output a report in the last wizard step, as the report is the only place where the
spike-in controls results will be available. During analysis, the spike-in data is added to the references. However, all traces of having used spike-ins are removed from the output tracks.

If spike-ins have been used, the quality control results are shown in the output report. So when using spike-in, make sure that the option to output a report is checked.

To learn how to import spike-in control files, see section 6.4.

28.1.2 Defining mapping options for RNA-Seq

When the reference has been defined, click **Next** and you are presented with the dialog shown in figure 28.5.

![Figure 28.5: Defining mapping parameters for RNA-Seq.](image)

The mapping parameters are identical to those applying to **Map Reads to Reference**, as the underlying mapping is performed in the same way. For a description of the parameters, please see section 25.1.3.

For the estimation of paired reads distances, RNA-Seq uses the transcript level reference sequence information. This means that introns are not included in the distance measurement. The paired distance measurement will only include transcript sequence, reflecting the true nature of the sequence on which the paired reads were produced.

In addition to the generic mapping parameters, two RNA-Seq specific parameters can be set:

- **Maximum number of hits for a read.** A read that matches equally well to more distinct places in the references than the 'Maximum number of hits for a read' specified will not be mapped (the notion of distinct places is elaborated below). If a read matches to multiple distinct places, but less than the specified maximum number, it will be randomly assigned to one of these places. The random distribution is done by the EM algorithm (see section 28.1.3)

  The definition of a distinct place in the references is complicated because each annotated transcript is extracted and used as reference for the read mapping (if the "Genome
annotated with genes and transcripts" is selected in figure 28.4). To exemplify, consider a gene with 10 transcripts and 11 exons, where all transcripts have exon 1, and each of the 10 transcripts have only one of the exons 2 to 11. Exon 1 will be represented 11 times in the references (once for the gene region and once for each of the 10 transcripts). Reads that match to exon 1 will thus match to 11 of the extracted references. However, when the mappings are considered in the coordinates of the main reference genome, it becomes evident that the 11 match places are not distinct but in fact identical. In this case this will just count as one distinct placement of the read, and it will not be discarded for exceeding the maximum number of hits limit. Similarly, when a multi-match read is randomly assigned to one of its match places, each distinct place is considered only once.

The limit for how many non-specific matches a read is allowed to have is applied first to the set of gene matches (if any), and then to intergenic matches. As an example using the default value of 10, if a read matches equally well 8 places within genes and 50 places in intergenic regions, it is still considered a valid match. It will only be discarded if the number of matches within genes is above the limit, or if there are no gene matches at all and the number of intergenic matches exceeds the limit.

Note that, although a read is mapped distinctly at the gene level, it does not necessarily map uniquely to a particular transcript of the gene. The above example with a gene with 10 transcripts and 11 exons, where all transcripts have exon 1, and each of the 10 transcripts have only one of the exons 2 to 11, is a good and easy to understand example of this: all reads that are mapped to exon 1 are uniquely mapped at the gene level but are non-specific matches at the transcript level. A more complicated example is that you may have a gene with transcript annotations where one transcript has a longer version of an exon than the other. In this case you may have reads that may either be mapped entirely within the long version of the exon, or across the exon-exon boundary of one of the transcripts with the short version of the exon. Such an example is provided by the gene 'Ftl1' in the example below (gene and mRNA annotations for that gene are shown in figure 28.6, along with the reads mapping to the gene).

When you zoom in on the regions at the end of the second exons and the beginning of the third exons (Figure 28.7) you see that the reference sequence is identical in the start of the part of the second exons that is only present in the long version, and in the start of the third exons (they share the sequence 'CTGCACA'). So a read that is '...TCATCTTGAGATGGCTTCTGCACA' may be either mapped entirely within the long version of the second exons, or across the exon-exon boundary of the short version of the second exon and the third exon. For reporting expression levels at the transcript level, reads are assigned among the transcripts to which they map by the Expectation Maximization algorithm.

- **Strand-specific alignment.** When this option is checked, the user can specify whether the reads should be mapped in the same orientation as the transcript from which they originate (forward) or in the reverse direction (reverse). This will typically be appropriate when a strand specific protocol for read generation has been used. It allows assignment of the reads to the right gene in cases where overlapping genes are located on different strands. Without the strand-specific protocol, this would not be possible (see [Parkhomchuk et al., 2009]). Note that when running RNA seq with the strand specific option turned on you can only make use of pairs in forward-reverse orientation, meaning that mate pairs are not supported.
28.1.3 The EM estimation algorithm

The EM estimation algorithm is inspired by the RSEM and eXpress methods. It iteratively estimates the abundance of transcripts/genes, and assigns reads to transcripts/genes according to these abundances.

To illustrate the interpretation of 'abundance', consider the following two examples:

In the first example, we have a gene with two transcripts, where one transcript is twice as long as the other (figure 28.8). This longer transcript is also twice as abundant, meaning that in the
exon common to both transcripts two of the three reads come from the longer transcript, and the final read comes from the shorter transcript. The longer transcript has a second exon which also generates two reads. We see then that the longer transcript is twice as abundant, but because it is twice as long it generates four times as many reads.

![Figure 28.8](image1.png)

**Figure 28.8:** The longer transcript has twice the abundance, but four times the number of reads as the shorter transcript.

In the second example, the set up is the same, but now the shorter transcript is twice as abundant as the longer transcript (figure 28.9). Because the longer transcript is twice as long, there are equal numbers of reads from each transcript.

![Figure 28.9](image2.png)

**Figure 28.9:** The longer transcript has half the abundance, but the same number of reads as the shorter transcript.

To estimate the transcript abundances, we carry out an expectation-maximization procedure. Before explaining the procedure, first we define the concept of a mapping. A mapping is a set of transcripts, to which a read may map. In the above examples, some reads have the mapping \( a_1 = \{t_1, t_2\} \) (these are non-uniquely mapping reads), and some reads have the mapping \( a_2 = \{t_2\} \) (these are ‘uniquely’ mapping reads). In both examples, the count of mapping \( a_1 \) is 3, because there are 3 shared reads between the transcripts. The count of mapping \( a_2 \) is 2 in the first example, and 1 in the second example.

The expectation-maximization algorithm proceeds as follows:

1. The transcript abundances are initialized to the uniform distribution, i.e. at the start all transcripts are assumed to be equally expressed.

2. Expectation step: the current (assumed) transcript abundances are used to calculate the expected count of each transcript, i.e. the number of reads we expect should be assigned to the given transcript. This is done by looping over all mappings that include the given transcript, and assigning a proportion of the total count of that mapping to the transcript. The proportion corresponds to the proportion of the total transcript abundance in the mapping that is due to the target.

3. Maximization step: the currently assigned counts of each transcript are used to re-compute the transcript abundances. This is done by looping over all targets, and for each target,
dividing the proportion of currently assigned counts for the transcript (=total counts for transcript/total number of reads) by the target length. This is necessary because longer transcripts are expected to generate proportionally more reads.

4. Repeat from step 2 until convergence.

Below, we illustrate how the expectation-maximization algorithm converges to the expected abundances for the above two examples.

Example 1:
Initially: transcript 2 abundance = 0.50, count: 0.00, transcript 1 abundance = 0.50, count: 0.00
After 1 round: transcript 2 abundance = 0.54, count: 3.50, transcript 1 abundance = 0.46, count: 1.50
After 3 rounds: transcript 2 abundance = 0.59, count: 3.70, transcript 1 abundance = 0.41, count: 1.30
After 4 rounds: transcript 2 abundance = 0.60, count: 3.76, transcript 1 abundance = 0.40, count: 1.24
After 5 rounds: transcript 2 abundance = 0.62, count: 3.81, transcript 1 abundance = 0.38, count: 1.19
After 6 rounds: transcript 2 abundance = 0.62, count: 3.85, transcript 1 abundance = 0.38, count: 1.15
After 7 rounds: transcript 2 abundance = 0.63, count: 3.87, transcript 1 abundance = 0.37, count: 1.13
After 9 rounds: transcript 2 abundance = 0.64, count: 3.92, transcript 1 abundance = 0.36, count: 1.08
After 10 rounds: transcript 2 abundance = 0.65, count: 3.93, transcript 1 abundance = 0.35, count: 1.07
After 11 rounds: transcript 2 abundance = 0.65, count: 3.94, transcript 1 abundance = 0.35, count: 1.06
After 12 rounds: transcript 2 abundance = 0.65, count: 3.95, transcript 1 abundance = 0.35, count: 1.05
After 13 rounds: transcript 2 abundance = 0.66, count: 3.96, transcript 1 abundance = 0.34, count: 1.04
After 14 rounds: transcript 2 abundance = 0.66, count: 3.97, transcript 1 abundance = 0.34, count: 1.03
After 15 rounds: transcript 2 abundance = 0.66, count: 3.97, transcript 1 abundance = 0.34, count: 1.03

Example 2:
Initially: transcript 2 abundance = 0.50, count: 0.00, transcript 1 abundance = 0.50, count: 0.00
After 1 round: transcript 2 abundance = 0.45, count: 2.50, transcript 1 abundance = 0.55, count: 1.50
After 3 rounds: transcript 2 abundance = 0.37, count: 2.18, transcript 1 abundance = 0.63, count: 1.82
After 4 rounds: transcript 2 abundance = 0.36, count: 2.12, transcript 1 abundance = 0.64, count: 1.88
After 6 rounds: transcript 2 abundance = 0.35, count: 2.08, transcript 1 abundance = 0.65, count: 1.92
After 7 rounds: transcript 2 abundance = 0.35, count: 2.06, transcript 1 abundance = 0.65, count: 1.94
After 8 rounds: transcript 2 abundance = 0.34, count: 2.04, transcript 1 abundance = 0.66, count: 1.96
After 9 rounds: transcript 2 abundance = 0.34, count: 2.03, transcript 1 abundance = 0.66, count: 1.97
After 10 rounds: transcript 2 abundance = 0.34, count: 2.02, transcript 1 abundance = 0.66, count: 1.98
After 11 rounds: transcript 2 abundance = 0.34, count: 2.01, transcript 1 abundance = 0.66, count: 1.99
After 12 rounds: transcript 2 abundance = 0.34, count: 2.01, transcript 1 abundance = 0.66, count: 1.99
After 14 rounds: transcript 2 abundance = 0.33, count: 2.00, transcript 1 abundance = 0.67, count: 2.00
After 15 rounds: transcript 2 abundance = 0.33, count: 2.00, transcript 1 abundance = 0.67, count: 2.00

Once the algorithm has converged, every non-uniquely mapping read is assigned randomly to a particular transcript according to the abundances of transcripts within the same mapping. The total transcript reads column reflects these assignments. The RPKM and TPM values are then computed from the counts assigned to each transcript.

28.1.4 Calculating expression values from RNA-Seq

When the reference has been defined, click Next and you are presented with the dialog shown in figure 28.10.

These parameters determine the way expression values are counted.
Count paired reads as two

The CLC Genomics Workbench supports the direct use of paired data for RNA-Seq. A combination of single reads and paired reads can also be used. There are three major advantages of using paired data:

- Since the mapped reads span a larger portion of the reference, there will be fewer non-specifically mapped reads. This means that generally there is a greater accuracy in the expression values.

- This in turn means that there is a greater chance of accurately measuring the expression of transcript splice variants. As single reads (especially from the short reads platforms) typically only span one or two exons, many cases will occur where expression of splice variants sharing the same exons cannot be determined accurately. With paired reads, more combinations of exons will be identified as being unique for a particular splice variant.\(^1\)

- It is possible to detect Gene fusions when one read in a pair maps in one gene and the other part maps in another gene. Several reads exhibiting the same pattern supports the presence of a fusion gene.

You can read more about how paired data are imported and handled in section 6.3.7.

When counting the mapped reads to generate expression values, the CLC Genomics Workbench needs to be told how to handle the counting of paired reads. The default behavior of the CLC Genomics Workbench is to count fragments (FPKM) rather than individual reads when two reads map as an intact pair. That is, an intact pair is given a count of one. Reads from a pair are considered part of a broken pair when the reads map outside the estimated pair distance, map in the wrong orientation, or only one of the reads of the pair maps. Neither member of a broken pair is counted when the default counting scheme is used. The reasoning is that when reads map as a broken pair, it is an indication that something is not right. For example, perhaps the transcripts are not represented correctly on the reference or there are errors in the data. In general, more confidence can be placed on an intact pair representing transcription within the sample. If a combination of paired and single reads are input into the analysis, then single reads that map are given a count of one. This is different from reads input into the analysis as part of a pair, but where their partner did not map.

In some situations it may be too strict to disregard broken pairs as is done using the default counting scheme. This could be the case where there is a high degree of variation in the sample.

\(^1\)Note that the CLC Genomics Workbench only calculates the expression of the transcripts already annotated on the reference.
compared to the reference or where the reference lacks comprehensive transcript annotations. By checking the Count paired reads as two option, you choose to count mapped ‘reads’ (RPKM) rather than mapped ‘fragments’ (FPKM). That means that, the two reads in an intact pair are each counted as one mapped read (so an intact pair contributes with a total count of two), and mapped members of broken pairs will each get given a count of one. Single mapped reads are also given a count of one. Note that this approach does not represent the abundance of fragments being sequenced correctly, since the two reads of a pair derive from the same fragment, whereas a fragment sequenced with single reads only give rise to one read.

Note that whether you choose to calculate RPKM or FPKM, the value will be given in a column called "RPKM" for all subsequent analysis.

**Expression value**

Please note that reads that map outside genes are counted as intergenic hits only and thus do not contribute to the expression values. If a read maps equally well to a gene and to an intergenic region, the read will be placed in the gene.

The expression values are created on two levels as two separate result files: one for genes and one for transcripts (if the "Genome annotated with genes and transcripts" is selected in figure 28.4). The content of the result files is described in section 28.1.5.

The Expression value parameter describes how expression per gene or transcript can be defined in different ways on both levels:

- **Total counts.** When the reference is annotated with genes only, this value is the total number of reads mapped to the gene. For un-annotated references, this value is the total number of reads mapped to the reference sequence. For references annotated with transcripts and genes, the value reported for each gene is the number of reads that map to the exons of that gene. The value reported per transcript is the total number of reads mapped to the transcript.

- **Unique counts.** This is similar to the above, except only reads that are uniquely mapped are counted (read more about the distribution of non-specific matches in section 28.1.2).

- **TPM.** (Transcripts per million). This is computed as $\frac{\text{RPKM} \cdot 10^6}{\sum \text{RPKM}}$, where the sum is over the RPKM values of all genes/transcripts.

- **RPKM.** This is a normalized form of the "Total counts" option (see more in section 28.1.4).

Please note that all values are present in the output. The choice of expression value only affects how Expression Tracks are visualized in the track view but the results will not be affected by this choice as the most appropriate expression value is automatically selected for the analysis being performed: for detection of differential expression this is the "Total counts" value, and for the other tools this is a normalized and transformed version of the "Total counts" as described below.

**Calculate expression for genes without transcripts**

For genes without annotated transcripts, the RPKM cannot be calculated since the total length of all exons is needed. By checking the Calculate expression for genes without transcripts, the
length of the gene will be used in place of an "exon length". If the option is not checked, there will be no RPKM value reported for those genes.

**Definition of RPKM**

RPKM, Reads Per Kilobase of exon model per Million mapped reads, is defined in this way [Mortazavi et al., 2008]:

\[
\text{RPKM} = \frac{\text{total exon reads}}{\text{mapped reads(millions)} \times \text{exon length (KB)}}.
\]

For prokaryotic genes and other non-exon based regions, the calculation is performed in this way:

\[
\text{RPKM} = \frac{\text{total gene reads}}{\text{mapped reads(millions)} \times \text{gene length (KB)}}.
\]

**Total exon reads**

This value can be found in the column with header **Total exon reads** in the expression track. This is the number of reads that have been mapped to exons (either within an exon or at the exon junction). When the reference genome is annotated with gene and transcript annotations, the mRNA track defines the exons, and the total exon reads are the reads mapped to all transcripts for that gene. When only genes are used, each gene in the gene track is considered an exon. When an un-annotated sequence list is used, each sequence is considered an exon.

**Exon length**

This is the number in the column with the header **Exon length** in the expression track, divided by 1000. This is calculated as the sum of the lengths of all exons (see definition of exon above). Each exon is included only once in this sum, even if it is present in more annotated transcripts for the gene. Partly overlapping exons will count with their full length, even though they share the same region.

**Mapped reads**

The sum of all mapped reads as listed in the RNA-Seq analysis report. If paired reads were used in the mapping, mapped fragments are counted here instead of reads, unless the Count paired reads as two option was selected. For more information on how expression is calculated in this case, see section 28.1.4.

### 28.1.5 Specifying RNA-Seq outputs

Clicking **Next** will allow you to specify the output options as shown in figure 28.11.

The main results of the RNA-Seq analysis are:

- **Expression Tracks** One track summarizing expression at the gene level is produced. The track name ends in (GE). If the "Genome annotated with genes and transcripts" option was selected, as shown in figure 28.4, then a second track summarizing expression at the transcript level is also produced. This track has a name ending with (TE).

- **Reads track** This track contains the mapping of the reads to the references. This track has a name ending with (Reads).

In addition, the following optional results can be selected:
CHAPTER 28. RNA-SEQ

Figure 28.11: Selecting the output of the RNA-Seq analysis.

- **Create list of unmapped reads.** Creates a list of the reads that either did not map to the reference at all or that were non-specific matches with more placements than specified (see section 28.1.2). If you started with paired reads then more than one list of unmapped reads may be produced: paired reads are put in one list, with a name that ends in (paired), singe reads, including members of broken pairs, are put in a read list with a name than ends in (single).

- **Create report.** Creates a report of the results. See RNA-Seq report below for a description of the information contained in the report. This report is also the only place results of the spike-in controls will be available.

- **Create fusion gene table.** An option that is enabled when using paired data. Creates a table that lists potential fusion genes. This, along with the Minimum read count, is described further below in section Gene fusion reporting.

### 28.1.6 Expression tracks

Both tracks can be shown in a Table and a Graphical view.

The expression track table view has the following options (figure 28.12).

- The "Filter to selection" only displays pre-selected rows in the table.
- The "Create track from Selection" will create a Track using selected rows.
- The "Select Genes in Other Views" button finds and selects the currently selected genes and transcripts in all other open expression track table views.
- The "Copy Gene Names to Clipboard" button copies the currently selected gene names to the clipboard.

By creating a Track list, the graphical view can be shown together with the read mapping track and tracks from other samples:

File | New | Track List
Select the mapping and expression tracks of the samples you wish to visualize together and select the annotation tracks used as reference for the RNA-Seq and click **Finish**.

Once the track list is shown, double-click the label of the expression track to show it in a table view.

Clicking a row in the table makes the track list view jump to that location, allowing for quick inspection of interesting parts of the RNA-Seq read mapping (see an example in figure 28.13).

Reads spanning two exons are shown with a dashed line between each end as shown in figure 28.13, and the thin solid line represents the connection between two reads in a pair.

When doing comparative analysis, double click on one of the Expression or Statistical Comparison tracks in a track list to get its table view. Then click on the "Select genes in other views" button in any other table or expression browser will cause the track list to zoom to the selected gene.

Expression tracks can also be used to annotate variants using the **Annotate with Overlap Information** tool. Select the variant track as input and annotate with the expression track. For variants inside genes or transcripts, information will be added about expression (counts, expression value etc) from the gene or transcript in the expression track. Read more about the annotation tool in section 23.6.1.

**Gene-level expression** The gene-level expression track (GE) holds information about counts and expression values for each gene. It can be opened in a **Table view** allowing sorting and filtering on all the information in the track (see figure 28.14 for an example subset of an expression track).

Each row in the table corresponds to a gene (or reference sequence, if the **One reference sequence per transcript** option was used). The corresponding counts and other information is shown for each gene:

- **Name**. The name of the gene, or the name of the reference sequence if "one reference sequence per transcript" is used.
Figure 28.13: RNA-Seq results shown in a split view with an expression track at the bottom and a track list with read mappings of two samples at the top.

- **Chromosome and region.** The position of the gene on the genome.

- **Expression value.** This is based on the expression measure chosen as described in section 28.1.4.

- **Gene length** The length of the gene as annotated.

- **TPM (Transcripts per million).** This is computed as \( \text{TPM} = \frac{\sum \text{RPKM}}{10^6} \), where the sum is over the RPKM values of all genes/transcripts (see [http://bioinformatics.oxfordjournals.org/content/26/4/493.long](http://bioinformatics.oxfordjournals.org/content/26/4/493.long)).

- **RPKM.** This is the expression value measured in RPKM [Mortazavi et al., 2008]: \( \text{RPKM} = \frac{\text{total exon reads}}{\text{mapped reads (millions) \times exon length (KB)}} \). See section 28.1.4 for a detailed definition.

- **Unique gene reads.** This is the number of reads that match uniquely to the gene or its transcripts.

- **Total gene reads.** This is all the reads that are mapped to this gene - both reads that map uniquely to the gene or its transcripts and reads that matched to more positions in the reference (but fewer than the 'Maximum number of hits for a read' parameter) which were assigned to this gene.

- **Transcripts annotated.** The number of transcripts annotated for the gene. Note that this is not based on the sequencing data - only on the annotations already on the reference sequence(s).
Figure 28.14: A subset of a result of an RNA-Seq analysis on the gene level. Not all columns are shown in this figure

- **Uniquely identified transcripts.** The number of transcripts with at least one mapped read that matches only that transcript and no others. Note that if a gene has 4 detected transcripts, and 8 undetected transcripts, all 4+8=12 transcripts will have the value "Uniquely identified transcripts = 4".

- **Exon length.** The total length of all exons (not all transcripts).

- **Exons.** The total number of exons across all transcripts.

- **Unique exon reads.** The number of reads that match uniquely to the exons (including across exon-exon junctions).

- **Total exon reads.** The total number of reads assigned to an exon or an exon-exon junction of this gene. As for the 'Total gene reads' this includes both uniquely mapped reads and reads with multiple matches that were assigned to an exon of this gene.

- **Ratio of unique to total (exon reads).** The ratio of the unique reads to the total number of reads in the exons. This can be convenient for filtering the results to exclude the ones where you have low confidence because of a relatively high number of non-unique exon reads.

- **Unique exon-exon reads.** Reads that uniquely match across an exon-exon junction of the gene (as specified in figure 28.13). The read is only counted once even though it covers several exons.

- **Total exon-exon reads.** Reads that match across an exon-exon junction of the gene (as specified in figure 28.13). As for the 'Total gene reads' this includes both uniquely mapped reads and reads with multiple matches that were assigned to an exon-exon junction of this gene.
- **Total intron reads.** The total number of reads that map to an intron of the gene.

- **Ratio of intron to total gene reads.** This can be convenient to identify genes with poor or lacking transcript annotations. If one or more exons are missing from the annotations, there will be a relatively high number of reads mapping in the intron.

**Transcript-level expression** If the "Genome annotated with genes and transcripts" option is selected in figure 28.4, a transcript-level expression track (TE) is also generated.

The track can be opened in a Table view allowing sorting and filtering on all the information in the track. Each row in the table corresponds to an mRNA annotation in the mRNA track used as reference.

- **Name.** The name of the transcript, or the name of the reference sequence if "one reference sequence per transcript" is used.

- **Chromosome and region.** The position of the gene on the genome.

- **Expression value.** This is based on the expression measure chosen as described in section 28.1.4.

- **TPM (Transcripts per million).** This is computed as \( \frac{\text{RPKM} \times 10^6}{\sum \text{RPKM}} \), where the sum is over the RPKM values of all genes/transcripts (see http://bioinformatics.oxfordjournals.org/content/26/4/493.long).

- **RPKM.** This is the expression value measured in RPKM [Mortazavi et al., 2008]: \( \text{RPKM} = \frac{\text{total exon reads}}{\text{mapped reads(millions)} \times \text{exon length (KB)}} \). See section 28.1.4 for a detailed definition.

- **Relative RPKM.** The RPKM for the transcript divided by the maximum of the RPKM values among all transcripts of the same gene. This value describes the relative expression of alternative transcripts for the gene.

- **Gene name.** The name of the corresponding gene.

- **Transcript length.** This is the length of the transcript.

- **Exons.** The total number of exons in the transcript.

- **Transcript ID.** The transcript ID is taken from the transcript_id note in the mRNA track annotations and can be used to differentiate between different transcripts of the same gene.

- **Transcripts annotated.** The number of transcripts based on the mRNA annotations on the reference. Note that this is not based on the sequencing data - only on the annotations already on the reference sequence(s).

- **Uniquely identified transcripts.** The number of transcripts with at least one mapped read that matches only that transcript and no others. Note that if a gene has 4 detected transcripts, and 8 undetected transcripts, all 4+8=12 transcripts will have the value "Uniquely identified transcripts = 4".

- **Unique transcript reads.** This is the number of reads in the mapping for the gene that are uniquely assignable to the transcript.
• **Total transcript reads.** Once the ‘Unique transcript read’ have been identified and their counts calculated for each transcript, the remaining (non-unique) transcript reads are assigned to one of the transcripts to which they match. The ‘Total transcript reads’ counts are the total number of reads that are assigned to the transcript once this assignment has been done. As for the assignment of reads among genes, the assignment of reads within a gene but among transcripts, is done by the EM estimation algorithm (section 28.1.3).

• **Ratio of unique to total (transcript reads).** The ratio of the unique reads to the total number of reads in the transcripts. This can be convenient for filtering the results to exclude the ones where you have low confidence because of a relatively high number of non-unique transcript reads.

**Additional information to GE or TE tracks** Both GE and TE tables can offer additional information such as hyperlinks to various databases (e.g., ENSEMBL, HGNC (HUGO Gene Nomenclature Committee), RefSeq, GeneID, etc.) In cases where the mRNA track or the gene track provided have biotype information, a biotype column will be added to the table.

28.1.7 **Reads track**

A track containing the mapped reads is generated. Details about viewing and editing of reads-tracks are described in section 23, and the resequencing is detailed in section 27.

If you have chosen the strand specific option when setting up your analysis, it may be helpful to note that the colors of mapped single reads represent the orientation of the read relative to the reference provided. When a gene track is provided along with the reference genome, the reads will be mapped using the strand you specified, but the coloring of the read will be relative to the reference gene. If the reads matches the orientation of the gene it is colored green, and if it is opposite to the orientation of the gene it is colored red. A summary list of the colors to expect with different combinations of gene orientation and strand specific mapping options is:

• Strand specific, forward orientation chosen + gene on plus strand of reference = single reads colored green.
• Strand specific, forward orientation chosen + gene on minus strand of reference = single reads colored red.
• Strand specific, reverse orientation chosen + gene on plus strand of reference = single reads colored red.
• Strand specific, reverse orientation chosen + gene on minus strand of reference = single reads colored green.

See figure 28.15 for an example of forward and reverse reads mapped to a gene on the plus strand.

**Note:** Reads mapping to intergenic regions will not be mapped in a strand specific way.

Although paired reads are coloured blue, they can be viewed as red and green ‘single’ reads by selecting the Disconnect paired reads box, within the Read Mapping Settings bar on the right-hand side of the track.
Figure 28.15: A track list showing a gene and transcript on the plus strand, and various mapping results. The first reads track shows a mapping of two reads (one 'forward' and one 'reverse') using strand specific 'both' option. Both reads map successfully; the forward read coloured green (because it matches the direction of the gene), and the reverse read coloured red. The second reads track shows a mapping of the same reads using strand specific ('forward') option. The reverse read does not map because it is not in the correct direction, therefore only the green forward read is shown. The final reads track shows a mapping of the same reads again but using strand specific ‘reverse’ option. This time, the green forward read does not map because it is in the wrong direction, and only the red reverse read is shown.

28.1.8 RNA-Seq report

An example of an RNA-seq report generated if you choose the Create report option is shown in figure 28.16.

The report is a collection of the sections described below, some sections included only based on the input provided when starting the tool. If a section is flagged with a pink highlight, it means that something has almost certainly gone wrong in the sample preparation or analysis. A warning message tailored to the highlighted section is added to the report to help troubleshoot the issue. The report can be exported in PDF or Excel format.

Selected input sequences Information about the sequence reads provided as input, including the number of reads in each sample, as well as information about the reference sequences used and their lengths.

References Information about the total number of genes and transcripts found in the reference:

- **Transcripts per gene.** A graph showing the number of transcripts per gene.
- **Exons per transcript.** A graph showing the number of exons per transcript.
- **Length of transcripts.** A graph showing the distribution of transcript lengths.
Spike-in quality control

- **Spike-in plot.** A plot shows the expression of each spike-in as a function of the known concentration of that spike-in (see figure 28.17 to see an optimal spike-in plot).

- **Summary table.** A table provides more details on the spike-in detection. Figure 28.18 shows a failed spike-in control, with a table where results that require attention are highlighted in pink.

Under the table, a **warning message** explains what the optimal value was, and offers some troubleshooting measures: When samples have poor correlation ($R^2 < 0.8$) between known
Figure 28.18: Summary table where less than optimal results are highlighted.

and measured spike-in concentrations, it indicates problems with the spike-in protocol, or a more serious problem with the sample. To troubleshoot, check that the correct spike-in file has been selected, and control the integrity of the sample RNA. Also, if fewer than 10000 reads mapped to spike-ins, check that the correct spike-in sequences are specified, and consider using more spike-in mix in future experiments.

Read quality control  This section includes:

- **A strand specificity table** that indicates the direction of the RNA fragment that generated the read. Strandedness can only be defined for reads that map to a gene or transcript. Of these reads, the number of "Reads with known strand" is used in determining the percentage of reads ignored due to being on the wrong strand, and the subsequent percentage of reads with the wrong strand. In a strand-specific protocol, almost all reads are generated from a specific orientation, but otherwise a mix of both orientations is expected.
  
  - A warning message will appear if over 90% of reads were mapped in the same orientation but the tool was run without using a strand specific setting ("Forward"/"Reverse").
  
  - If over 25% of the reads were filtered away due to the strand specific setting, try to re-run the tool with strand specific setting "Both". However, if a strand-specific protocol was used, library preparation may have failed.

- **A percentage of mapped paired-end reads containing read-through adapters.** If present in above 10% of the reads, adapters may lead to false positive variant calls or incorrect transcript quantification (because reads must align within transcript annotations to be counted towards expression). Read-through adapters can be removed using the Trim Reads tool. Note that single base extensions such as TA overhangs will also be classed as read-through adapters, and in these cases the additional base should also be trimmed. In future experiments, consider selecting fragments that are longer than the read size.
- A **paired distance graph** (only included if paired reads are used) shows the distribution of paired-end distances, which is equivalent to the distribution of sequenced RNA fragment sizes. There should be a single broad peak at the target fragment size. An asymmetric peak may indicate problems in size selection.

**Mapping statistics**  Shows statistics on:

- **Paired reads** or **Single reads**. The table included depends on the reads used. The table shows the number of reads mapped or unmapped, and in the case of paired reads, how many reads mapped in pairs and in broken pairs.

  If over 50% of the reads did not map, and the correct reference genome was selected, this indicates a serious problem with the sample. To troubleshoot, the report offers the following options:

  - Check that the correct reference genome and any relevant gene/mRNA tracks have been provided.
  - The mapping parameters may be too strict. Try resetting them to the default values.
  - Try mapping the un-mapped reads against possible contaminants. If the sample is contaminated, enrich for the target species before library preparation in future experiments.
  - Library preparation may have failed. Check the quality of the sample RNA.

In case paired reads are used and over 40% of them mapped as broken pairs, the report hints that there could be problems with the tool settings, a low quality reference sequence, or incomplete gene/mRNA annotations. It could also indicate a more serious problem with the sample. To troubleshoot, it is suggested to:

  - Check that the correct reference genome and any relevant gene/mRNA tracks have been provided.
  - Try re-running the tool with the "Auto-detect paired distances" option selected.
  - Check that the paired-end distances on the reads are set correctly. These are shown in the "Element Information" view on the reads. If these are correct, try re-running the tool without the "Auto-detect paired distances" option.
  - Try mapping the reads against possible contaminants. If the sample is contaminated, enrich for the target species before library preparation in future experiments.

- **Match specificity**. Shows a graph of the number of match positions for the reads. Most reads will be mapped 0 or 1 time, but there will also be reads matching more than once in the reference. The maximum number of match positions is limited in the **Maximum number of hits for a read** setting in figure 28.4. Note that the number of reads that are mapped 0 times includes both the number of reads that cannot be mapped at all and the number of reads that matches to more than the **Maximum number of hits for a read** parameter.

**Fragment statistics**

- **Fragment counting**. Lists the total number of fragments used for calculating expression, divided into uniquely and non-specifically mapped reads, as well as uncounted fragments (see the point below on match specificity for details).
- **Counted fragments by type.** Divides the fragments that are counted into different types, e.g., uniquely mapped, non-specifically mapped, mapped. A last column gives the percentage of fragments mapped for a particular type.
  - **Total gene reads.** All reads that map to the gene.
  - **Intron.** From the total gene reads, reads that fall partly or entirely within an intron.
  - **Exon.** From the total gene reads, reads that fall entirely within an exon or in an exon-exon junction.
  - **Exon.** From the total gene-exon reads, reads that map completely within an exon
  - **Exon-exon.** From the total gene-exon reads, reads that map across an exon junction as specified in figure 28.13.
  - **Intergenic.** All reads that map partly or entirely between genes.
  - **Total.** Total amount of reads for a particular type.

**Distribution of biotypes** Table generated from biotype annotations present on the input gene or mRNA tracks. If using both gene and mRNA tracks, the biotypes in the report are taken from the mRNA track.

- For genes, biotypes can be any of the following columns: "gene_biotype", "biotype", "gbkey", "type". The first one in this list is chosen.
- For transcripts, biotypes can be any of the following columns: "transcript_biotype", "biotype", "gbkey", "type". The first one in this list is chosen.

The biotypes are "as a percentage of all transcripts" or "as a percentage of all genes". For a poly-A enrichment experiment, it is expected that the majority of reads correspond to protein-coding regions. For an rRNA depletion protocol, a variety of non-coding RNA regions may also be observed. The percentage of reads mapping to rRNA should usually be <15%.

If over 15% of the reads mapped to rRNA, it could be that the poly-A enrichment/rRNA depletion protocol failed. The sample can still be used for differential expression and variant calling, but expression values such as TPM and RPKM may not be comparable to those of other samples. To troubleshoot the issues in future experiments, check for rRNA depletion prior to library preparation. Also, if an rRNA depletion kit was used, check that the kit matches the species being studied.

**Gene/transcript length coverage** Plot showing the normalized coverage across a gene/transcript body for four different groupings of gene/transcript length (figure 28.19).

To generate this plot, every transcript is rescaled to have a length of 100. For every read that is assigned to a transcript, we get its start and end coordinates in this "transcript-length-normalized" coordinate system [0,100]. We then increment counters from the read start position to the read end position. After all the reads have been counted, the average 5' count is the average value of the counters at position 0,1,2...49. The average 3' count is the value at positions 51,52,53...100. The difference between average 3' and 5' normalized counts is the difference between these values as a percentage of the maximum number of counts seen at any position.
Figure 28.19: Gene/transcript length coverage plot.

The lines should be flat in the center of the plot, and the plot should be approximately symmetric. An erratic line may indicate that there are few genes/transcripts in the given length range. Lines showing normalized count higher on the 3’end indicates the presence of polyA tails in the reads, consequence of degraded RNAs. Future experiments may benefit from using an rRNA depletion protocol.

In the table below the plot, a difference between average 3’ and 5’ normalized counts higher than 25 warns that variants may not be called in low coverage regions, and that TPM or RPKM values may be unreliable. Most transcripts are <10000 bp long, so a warning is raised if many reads map to features longer than this. One possible cause is that no mRNA track has been provided for an organism with extensive splicing.

### 28.1.9 Gene fusion reporting

When using paired data, there is also an option to create an annotation track summarizing the evidence for gene fusions. An example is shown in figure 28.20.

Each row represents one gene where read pairs suggest it could be fused with another gene. This means that each fusion is represented by two rows.

The **Minimum read count** option in figure 28.11 is used to make sure that only combinations of genes supported by at least this number of read pairs are included. The default value is 5, which means that at least 5 pairs need to connect two genes in order to report it in the result.

The result table shows the following information for each row:

- **Name.** The name of the fusion (the two gene names combined).
- **Information per gene.** Gene name, chromosome and position are included for both genes.
CHAPTER 28. RNA-SEQ 774

Figure 28.20: An example of a gene fusion table.

- **Reads.** How many reads that are mapped across the two genes.

Note that the reporting of gene fusions is very simple and should be analyzed in much greater detail before any evidence of gene fusions can be verified. The table should be considered more of a pointer to genes to explore rather than evidence of gene fusions. Please note that you can include the fusion genes track in a track list together with the reads tracks to investigate the mapping patterns in greater detail:

```
File | New | Track List (i)
```

### 28.2 Create Combined RNA-Seq Report

With the Create Combined RNA-Seq Report tool, you can generate an overview of several RNA-seq experiments by combining in one document several RNA-Seq reports. The description of the various sections included in the report, as well as the cutoff values that trigger warnings for sub-optimal data are the same as described for RNA-Seq reports (see section 28.1.8). The combined report can be exported in PDF or Excel format.

To start the tool:

```
Toolbox | RNA-Seq Analysis (c) | Create Combined RNA-Seq Report
```

In the wizard that opens (figure 28.21), select several RNA-seq reports and click **Next.** Note that while it seems possible to select any kind of reports in that dialog, only RNA-seq reports generated by **CLC Genomics Workbench 12.0** or higher will be compiled in the combined RNA-seq report.

In the Result handling window, choose whether you want to open or save the combined report. When saving, specify where you would like to save the combined report in the Navigation Area, and click **Finish.**

The results of the individual reports are compiled in tables, and organized in the same sections than the ones were present in the individual input reports. This layout enables a quick overview...
of a series of experiments as well as the different troubleshooting options for dealing with sub-optimal data quality (see figure 28.22 for an example of the first four sections of a combined report).

### 1 Read count statistics

<table>
<thead>
<tr>
<th>Sample name</th>
<th>Read count</th>
<th>Single, mapped %</th>
<th>Single, unmapped %</th>
<th>Paired, mapped pairs %</th>
<th>Paired, broken pairs %</th>
<th>Paired, not mapped %</th>
</tr>
</thead>
<tbody>
<tr>
<td>Report2</td>
<td>1,000,000</td>
<td>N/A</td>
<td>N/A</td>
<td>39.96</td>
<td>3.69</td>
<td>N/A</td>
</tr>
<tr>
<td>Report1</td>
<td>2,756,262</td>
<td>N/A</td>
<td>N/A</td>
<td>93.21</td>
<td>4.13</td>
<td>N/A</td>
</tr>
</tbody>
</table>

For paired data, there are two reads in a pair.

### 2 Fragment counting statistics

<table>
<thead>
<tr>
<th>Sample name</th>
<th>Mapped to genes %</th>
<th>Mapped to intergenic %</th>
</tr>
</thead>
<tbody>
<tr>
<td>Report2</td>
<td>67.50</td>
<td>32.50</td>
</tr>
<tr>
<td>Report1</td>
<td>98.51</td>
<td>1.49</td>
</tr>
</tbody>
</table>

Default counting scheme (Fragment counts): An intact pair is counted as one, broken pairs are ignored.

### 3 Spike-in quality control

<table>
<thead>
<tr>
<th>Sample name</th>
<th>Detected spike-ins</th>
<th>R²</th>
<th>Reads mapped to spike-ins</th>
<th>% of reads mapped to spike-ins</th>
<th>Lower limit of detection (attomoles/μL)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Report2</td>
<td>48/92</td>
<td>0.05</td>
<td>7,338</td>
<td>3.19</td>
<td>0.03</td>
</tr>
<tr>
<td>Report1</td>
<td>54/92</td>
<td>0.97</td>
<td>24,867</td>
<td>1.76</td>
<td>7.22</td>
</tr>
</tbody>
</table>

R²: The sample has poor correlation (R² < 0.8) between known and measured spike-in concentrations. This may indicate problems with the spike-in protocol, or a more serious problem with the sample.

- Check that the correct spike-in file has been selected.
- Check the integrity of the sample RNA.

Reads mapped to spike-ins: Fewer than 10,000 reads mapped to spike-ins.

- Check the integrity of the sample RNA.
- Consider using more spike-in mix in future experiments.

### 4 Strand specificity

<table>
<thead>
<tr>
<th>Sample name</th>
<th>Strand specific setting</th>
<th>Forward % of reads mapped</th>
<th>Reverse % of reads mapped</th>
<th>Ignored reads (wrong strand)</th>
<th>Ignored reads % (wrong strand)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Report2</td>
<td>Both</td>
<td>50.50</td>
<td>49.50</td>
<td>0</td>
<td>0.00</td>
</tr>
<tr>
<td>Report1</td>
<td>Both</td>
<td>95.01</td>
<td>4.99</td>
<td>1,544</td>
<td>0.06</td>
</tr>
</tbody>
</table>

Strand specific setting: >90% of reads were mapped in the same orientation. Consider re-running the tool with a strand specific setting ("Forward" or "Reverse").
28.3 PCA for RNA-Seq

Principal Component Analysis makes it possible to project a high-dimensional dataset (where the number of dimensions equals the number of genes or transcripts) onto two or three dimensions. This helps in identifying outlying samples for quality control, and gives a feeling for the principal causes of variation in a dataset. The analysis proceeds by transforming a large set of variables (in this case, the counts for each individual gene or transcript) to a smaller set of orthogonal principal components. The first principal component specifies the direction with the largest variability in the data, the second component is the direction with the second largest variation, and so on.

The **PCA for RNA-Seq** tool clusters samples in 2D or 3D. Known metadata about each sample is added as an overlay. To start the analysis:

Toolbox | RNA-Seq Analysis | PCA for RNA-Seq

Select a number of expression tracks and click Next.

### 28.3.1 Principal component analysis plot (2D)

The default view is a two-dimensional principal component plot as shown in figure 28.23.

![Figure 28.23: A principal component plot.](image)

The plot shows the projection of the samples onto the two-dimensional space spanned by the first and second principal components of the covariance matrix. The expression levels used as input are normalized log CPM values, see section 28.

The view settings can be adjusted using the **Side Panel**. Under **Graph preferences**, you can adjust the general properties of the plot.
• **Lock axes** This will always show the axes even though the plot is zoomed to a detailed level.

• **Frame** Shows a frame around the graph.

• **Tick type** Determines whether tick lines should be shown outside or inside the frame.

• **Tick lines at** Choosing Major ticks will show a grid behind the graph.

• **Horizontal axis range** Sets the range of the horizontal axis (x axis). Enter a value in Min and Max, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.

• **Vertical axis range** Sets the range of the vertical axis (y axis). Enter a value in Min and Max, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.

• **y = 0 axis** Draws a line where y = 0 with options for adjusting the line appearance.

Below the general preferences, you find the **Dot properties**:

• **Drop down menu** In this you select the expression tracks to which following choices apply.

• **Dot type** Allows you to choose between different dot types.

• **Dot color** Click the color box to select a color.

• **Show name** This will show a label with the name of the sample next to the dot.

Note that the Dot properties may be overridden when the Metadata options are used to control the visual appearance (see below).

The **Principal Components** group determines which two principal components are used in the 2D plot. By default, the first principal component is shown for the X axis and the second principal component is shown for the Y axis. The value after the principal component identifier (for example "PC1 (72.5 %)") displays the amount of variance explained by this particular principal component.

The **Metadata** group allows metadata associated with the Expression tracks to be visualized in a number of ways:

• **Symbol color** Colors are assigned based on a categorical factor in the metadata table.

• **Symbol shape** Shape is assigned based on a categorical factor in the metadata table.

• **Label text** Dots are labeled according to the values in a given metadata column.

• **Legend font settings** contains options to adjust the display of labels.

The graph and axes titles can be edited simply by clicking them with the mouse. These changes will be saved when you **Save** the graph - whereas the changes in the **Side Panel** need to be saved explicitly (see section 4.6).
28.3.2 Principal component analysis plot (3D)

The principal component plot may also be displayed in 3D. The 3D view is accessible through the view buttons at the bottom of the panel.

Notice that the 3D PCA rendering feature requires a graphics card capable of supporting OpenGL 2.0. Please make sure the latest driver for the graphics card is installed. Indirect rendering (such as x11 forwarding through ssh), remote desktop connection/VNC, and running in virtual machines is not supported.

![Figure 28.24: A principal component 3D plot.](image)

The 3D view may be rotated by dragging on the view with the left mouse button pressed. It is possible to pan the view by dragging with the right mouse button pressed. Zooming can be done either using the mouse scroll wheel, or by dragging with both left and right mouse button pressed. It is also possible to center and zoom to a sample simply by clicking on it. Clicking outside any sample (or clicking with the right mouse button) restores the zoom and centering.

The Side Panel offers a number of options to change the appearance of the 3D principal component plot:

- The View settings group makes it possible to toggle the coordinate system on and off, and adjust the text and background color. It is also possible to enable Fog, which dims distant objects in order to improve the depth perception.

- The Principal Components group determines which principal components are used in the 3D plot. The value after the principal component identifier (for example "PC 1 (72.5 %)") displays the amount of variance explained by this particular principal component.
The Metadata group allows metadata associated with the Expression tracks to be visualized using color or as text:

- **Symbol color** Colors are assigned based on a categorical factor in the metadata table.
- **Label text** Samples are labeled according to the values in a given metadata column. If 'Show names' is selected, the samples will be labeled according to their name (as shown in the Navigation Area).

To save the current view as an image, press the Graphics button in the Workbench toolbar. Next, select the location where you wish to save the image, select file format (PNG, JPEG, or TIFF), and provide a name, if you wish to use another name than the default name.

It is possible to save the current view settings (including camera settings) using the Side Panel view settings options, see section 4.6.

### 28.4 Differential Expression

Two tools are available in the Workbench for calculating differential expressions. The **Differential Expression in Two Groups** tool performs a statistical differential expression test for a set of Expression Tracks and a set of control tracks. The **Differential Expression for RNA-Seq** tool performs a statistical differential expression test for a set of Expression Tracks with associated metadata. Both tools use multi-factorial statistics based on a negative binomial Generalized Linear Model (GLM).

**How many replicates do I need?** The Differential Expression for RNA-Seq tool is capable of running without replicates, but this is not recommended and the results should be treated with caution. In general it is desirable to have as many biological replicates as possible – typically at least 3. Replication is important in that it allows the ‘within group’ variation to be accurately estimated for a gene. In the absence of replication, the Differential Expression for RNA-Seq tool assumes that genes with similar average expression levels have similar variability.

**Technical or biological replicates?** [Auer and Doerge, 2010] illustrates the importance of biological replicates with the example of an alien visiting Earth. The alien wishes to know if men are taller than women. It abducts one man and one woman, and measures their heights several times i.e. performs several technical replicates. However, in the absence of biological replicates, the alien would erroneously conclude that women are taller than men if this was the case in the two abducted individuals.

The use of the GLM formalism allows us to fit curves to expression values without assuming that the error on the values is normally distributed. Similarly to edgeR and DESeq, we assume that the read counts follow a Negative Binomial distribution as explained in McCarthy et al., 2012. The Negative Binomial distribution can be understood as a ‘Gamma-Poisson’ mixture distribution i.e., the distribution resulting from a mixture of Poisson distributions, where the Poisson parameter λ is itself Gamma-distributed. In an RNA-Seq context, this Gamma distribution is controlled by the dispersion parameter, such that the Negative Binomial distribution reduces to a Poisson distribution when the dispersion is zero.
CHAPTER 28. RNA-SEQ

To learn more about the performance of the Differential Expression Analysis tool in comparison to well-accepted protocols like DEseq, EdgeR, read our benchmark results here: https://www.qiagenbioinformatics.com/blog/discovery/lasting-expressions/.

28.4.1 The GLM model

Fitting a GLM to expression data

It is easiest to understand how the GLM model works through an example. Imagine an experiment looking at the effect of two drug treatments while controlling for gender:

- Test differential expression due to Treatment with three groups: drugA, drugB, placebo
- While controlling for Gender with groups: Male, Female

In an abuse of mathematical notation, the underlying GLM for each gene looks like

\[
\log y_i = \text{(placebo and Male)} + \text{drugA} + \text{drugB} + \text{Female} + \text{constant}_i
\]  

(28.1)

where \( y_i \) is the expression level for the gene in sample \( i \); the combined term \( \text{(placebo and Male)} \) describes an arbitrarily chosen baseline expression level (of males being given a placebo); and the other terms \( \text{drugA}, \text{drugB} \text{ and Female} \) are numbers describing the effect of each group with respect to this baseline. The \( \text{constant}_i \) accounts for differences in the library size between samples. For example, if a subject is male and given a placebo we predict the expression level to be

\[
\log y_i = \text{(placebo and Male)} + \text{constant}_i.
\]

If instead he had been given drug B, we would predict the expression level \( y_i \) to be augmented with the \( \text{drugB} \) coefficient, resulting in

\[
\log y_i = \text{(placebo and Male)} + \text{drugB} + \text{constant}_i.
\]

We assume that the expression levels \( y_i \) follow a Negative Binomial distribution. This distribution has a free parameter, the dispersion. The greater the dispersion, the greater the variation in expression levels for a gene.

The most likely values of the dispersion and coefficients, \( \text{drugA}, \text{drugB} \text{ and Female} \), are determined simultaneously by fitting the GLM to the data. To see why this simultaneous fitting is necessary, imagine an experiment where we observe counts \{3,10,4\} for Males and \{30,20,8\} for Females. The most natural fit is for the coefficient Female to have a two-fold change and for the dispersion to be small, but an alternative fit has no fold change and a larger dispersion. Under this second fit the variation in the counts is greater, and it is just by chance that all three Female values are larger than all three Male values.

Refining the estimate of dispersion

Much research has gone into refining the dispersion estimates of GLM fits. One important observation is that the GLM dispersion for a gene is often too low, because it is a sample
dispersion rather than a population dispersion. We correct for this using the Cox-Reid adjusted likelihood, as in the multi-factorial edgeR method [Robinson et al., 2010].

A second observation that can be used to improve the dispersion estimate, is that genes with the same average expression often have similar dispersions. To make use of this observation, we follow [Robinson et al., 2010] in estimating gene-wise dispersions from a linear combination of the likelihood for the gene of interest and neighboring genes with similar average expression levels. The weighting in this combination depends on the number of samples in an experiment, such that the neighbors have most weight when there are no replicates, and little effect when the number of replicates is high.

For dispersion, we used the following strategy:

1. We sort the genes from lowest to highest averageLogCPM (CPM is defined also by the edgeR authors) For each gene, we calculate its loglikelihood at a grid of known dispersions. The known dispersions are $0.2 \times 2^i$, where $i = -6, -4.8, -3.6...6$ such that there are 11 values of $i$ in total. You can imagine the results of this as being stored in an array with one column for each gene and one row for each dispersion, with neighboring columns having similar averageLogCPM (because of the sorting in the previous step).

2. We now calculate a weighted loglikelihood for each gene at these same known dispersions. This is the original loglikelihood for that gene at that dispersion plus a "weight factor" multiplied by the average loglikelihood for genes in a window of similar averageLogCPM. The window includes the 1.5% of genes to the left and to the right of the gene we are looking at. For example, if we had 3000 genes, and were calculating values for gene 500, then $0.015 \times 3000 = 45$, so we would average the values for genes 455 to 545. The "weight factor" = $20 / (numberOfSamples \cdot number of parameters in the factor being tested)$. This means that the greater the number of samples, the lower the weight, and the fewer free parameters to fit, the lower the weight.

3. We fit an FMM spline for each gene to its 11 weighted loglikelihoods. Our implementation of the FMM spline is translated from the Fortran code found here http://www.netlib.org/fmm/spline.f This spline allows us to estimate the weighted log-likelihood at any dispersion within the grid i.e., from $0.2 \times 2^{-6}$ to $0.2 \times 2^6$

4. We find the dispersion on the spline that maximizes the loglikelihood. This is the dispersion we use for that gene.

**Statistical testing**

The final GLM fit and dispersion estimate allows us to calculate the total likelihood of the model given the data, and the uncertainty on each fitted coefficient. The two statistical tests each make use of one of these values.

**Wald test** Tests whether a given coefficient is non-zero. This test is used in the All group pairs and Against control group comparisons. For example, to test whether there is a difference between subjects treated with a placebo, and those treated with drugB, we would use the Wald test to determine if the drugB coefficient is non-zero.

---

2To understand the purpose of the correction, it may help to consider the analogous situation of calculation of the variance of normally distributed measurements. One approach would be to calculate $\frac{1}{n} \sum (x_i - \bar{x})^2$, but this is the sample variance and often too low. A commonly used correction for the population variance is: $\frac{1}{n-1} \sum (x_i - \bar{x})^2$. 

**Likelihood Ratio test** Fits two GLMs, one with the given coefficients and one without. The more important the coefficients are, the greater the ratio of the likelihoods of the two models. This test is used in the Across groups (ANOVA-like) comparison. If we wanted to test whether either drug had an effect, we would compare the likelihoods of the GLM described in equation 28.1 with those in the reduced GLM \( \log y_i = (\text{Male}) + \text{Female} + \text{constant}_i \).

### 28.4.2 Differential Expression in Two Groups

The **Differential Expression in Two Groups** tool performs a statistical differential expression test for a set of Expression Tracks and a control. It uses multi-factorial statistics based on a negative binomial GLM as described in section 28.4.1. Differential Expression in Two Groups only handles one factor and two groups, as opposed to the Differential Expression for RNA-Seq tool that can handle multiple factors and multiple groups.

To run the Differential Expression in Two Groups analysis:

**Toolbox | RNA-Seq Analysis | Differential Expression in Two Groups**

In the first dialog (figure 28.25), select a number of Expression tracks (GE or TE) and click **Next**. For Transcripts Expression Tracks (TE), the values used as input are "Total transcript reads". For Gene Expression Tracks (GE), the values used depend on whether an eukaryotic or prokaryotic organism is analyzed, i.e., if the option "Genome annotated with Genes and transcripts" or "Genome annotated with Genes only" was used. For Eukaryotes the values are "Total Exon Reads", whereas for Prokaryotes the values are "Total Gene Reads".

Note that the tool can be run in batch mode, albeit with the same control group expression for all selected batch units.

![Figure 28.25: Select expression tracks for analysis.](image)

In the **Settings** dialog, select a number of control Expression tracks (GE or TE). A warning message (as seen in figure 28.26) appears if only one track is selected for either the input or the control group: such a setting does not provide replicates, thus does not ensure sufficient statistical power to the analysis.

![Figure 28.26: Select enough control expression tracks to ensure that replicates are provided.](image)
The output of the tool is a comparison table study vs. control that can be visualized as a Statistical comparison track (section 28.4.4) and a Volcano plot (section 28.4.4).
28.4.3 Differential Expression for RNA-Seq

The **Differential Expression for RNA-Seq** tool performs a statistical differential expression test for a set of Expression Tracks. It uses multi-factorial statistics based on a negative binomial GLM. The tool supports paired designs and can control for batch effects. The statistical analysis is described in more detail in section 28.4.1.

To run the Differential Expression for RNA-Seq analysis:

**Toolbox | RNA-Seq Analysis | Differential Expression for RNA-Seq**

Select a number of Expression tracks and click **Next** figure 28.27.

![Figure 28.27: Select a number of Expression tracks.](image)

For Expression Tracks (TE), the values used as input are "Total transcript reads". For Gene Expression Tracks (GE), the values used depend on whether an eukaryotic or prokaryotic organism is analyzed, i.e. if the option "Genome annotated with Genes and transcripts" or "Genome annotated with Genes only" is used. For Eukaryotes the values are "Total Exon Reads", whereas for Prokaryotes the values are "Total Gene Reads".

The normalization options available can be seen in figure 28.28.

![Figure 28.28: Normalization methods.](image)

First, choose the application that was used to generate the expression tracks selected at the previous step: Whole transcriptome RNA-Seq, Targeted RNA-Seq and Small RNA. For Targeted RNA-Seq and Small RNA, you can choose between two normalization methods: TMM and
Housekeeping genes, while Whole transcriptome RNA-Seq will be normalized by default using the TMM method.

TMM Normalization (Trimmed Mean of M values) calculates effective libraries sizes, which are then used as part of the per-sample normalization. TMM normalization adjusts library sizes based on the assumption that most genes are not differentially expressed.

Normalization with Housekeeping genes for can be done when a set of housekeeping genes to use is available: in the "Custom housekeeping genes" field, type the name of the genes separated by a space. Finally choose between these two options:

- **Use only the most stable housekeeping genes** will use a subset (at least three) of the most stable genes for normalization, these being defined using the GeNorm algorithm [Vandesompele et al., 2002].
- **Use all housekeeping genes** keep all housekeeping genes listed for normalization.

When working with Targeted RNA Panels, it is recommended to normalize with the Housekeeping genes method rather than TMM. Predefined list of housekeeping genes are available for samples generated using Human and Mouse QIAseq panels (hover with the mouse on the dialog to find the list of genes included in the set). If you are working with a custom panel, you can also provide the corresponding set of housekeeping genes in the "Custom housekeeping genes" as described above.

In the Experimental design panel (figure 28.29), a Metadata table must be selected that describes the factors and groups for all the samples.

![Figure 28.29: Setting up the experimental design and comparisons.](image)

- **Metadata table** The metadata table describing the factors for the selected Expression tracks.
- **Test differential expression due to** Specify the one factor differential expression is tested for.
- **While controlling for** Specify confounding factors, i.e., factors that are not of primary interest, but may affect gene expression.
The Comparisons panel determines the number and type of statistical comparison tracks output by the tool (see section 28.4.4 for more details).

The Differential Expression for RNA-Seq tool produces different numbers and types of statistical comparison tracks depending on the settings of the Comparisons panel. Depending on the choice either a Wald test or a Likelihood Ratio test is used. For example, assume that we test a factor called ‘Tissue’ with three groups: skin, liver, brain.

- **Across groups (ANOVA-like)** This mode tests for the effect of a factor across all groups.
  - *Outputs produced:* "Due to Tissue"
  - *Test used:* Likelihood ratio test
  - *Fold change reports:* The maximum pairwise fold change between any two of the three tissue types.
  - *Max of group means reports:* The maximum of the average group RPKM values among any of the tissue types for a gene.

- **All group pairs** tests for differences between all pairs of groups in a factor.
  - *Outputs produced:* "skin vs. liver", "skin vs. brain", "liver vs. brain"
  - *Test used:* Wald test
  - *Fold change reports:* The fold change in the defined order between the named pair of tissue types.
  - *Max of group means reports:* The maximum of the average group RPKM values between the two named tissue types.

- **Against control group** This mode tests for differences between all the groups in a factor and the named reference group. In this example the reference group is skin.
  - *Outputs produced:* "liver vs. skin", "brain vs. skin"
  - *Test used:* Wald test
  - *Fold change reports:* The fold change in the defined order between the named pair of tissue types.
  - *Max of group means reports:* The maximum of the average group RPKM values between the two named tissue types.

Note: Fold changes are calculated from the GLM, which corrects for differences in library size between the samples and the effects of confounding factors. It is therefore not possible to derive these fold changes from the original counts by simple algebraic calculations.

### 28.4.4 Output of the Differential Expression tools

#### Statistical comparison tracks

The Differential Expression for RNA-Seq tool will output one or more statistical comparison tracks or tables. The statistical comparison table offers the same functionality than the track, except for the track view.
An example of a statistical comparison track is shown in figure 28.30. Statistical comparison tracks make it possible to show differential expression data alongside other kinds of tracks in a genomic context.

In particular, the Fold Change value will tell you how expression levels in group 2 are relative to that in group 1.

- If expression values in group 2 are twice as large as in group 1, the fold change will be +2.
- If expression values in group 1 are twice as large as in group 2, the fold change will be -2.

Note that it is not possible to derive these fold changes from the CPM values by simple algebraic calculations as the Differential Expression for RNA-Seq tool works by fitting a statistical model (which accounts for differences in sequencing-depth) to raw counts. Keep also in mind that p-values smaller than 1.11e-16 will be reported as equal to zero, and as a consequence these values will appear on the volcano plot with fixed y=16.

The track layout of the statistical comparison track can be customized as follows:

- **Data aggregation** Allows you to specify whether the information in the track should be shown in detail or whether you wish to aggregate data. By aggregating data you decrease the detail level, but increase the speed of the data display process, which is of particular interest when working with big data sets. The threshold (in bp) for when data should be aggregated can be specified with the drop-down box. The threshold describes the unit (or "bucket") size in base pairs, above which the data will start being aggregated. The bucket size depends on the track length and the zoom level. Hence, a data aggregation threshold with a low value will only show details when zoomed in, whereas a high value means that you can see details even when zoomed out. Please note that when using the high values, it will take longer time to display the data on the screen.

- **Bar plot color** Selects the color of aggregated data.
• **Labels** Determines where the gene name should be shown.

• **Annotation value** The value that is graphically shown in detail view:
  
  - **Max group means** For each group in the statistical comparison, the average RPKM is calculated. This value is the maximum of the average RPKM’s.
  
  - **Log$_2$ fold change** The logarithmic fold change.
  
  - **Fold change** The (signed) fold change. Genes/transcripts that are not observed in any sample have undefined fold changes and are reported as NaN (not a number).
  
  - **P-value** Standard p-value. Genes/transcripts that are not observed in any sample have undefined p-values and are reported as NaN (not a number).
  
  - **FDR p-value** The false discovery rate corrected p-value.
  
  - **Bonferroni** The Bonferroni corrected p-value.

• **Annotation color** Determines how the annotation value is mapped onto a color.

The expression track table view has the following options:

• The "Filter to selection" only displays pre-selected rows in the table.

• The "Create track from Selection" will create a Track using selected rows.

• The "Select Genes in Other Views" button finds and selects the currently selected genes and transcripts in all other open expression track table views.

• The "Copy Gene Names to Clipboard" button copies the currently selected gene names to the clipboard.

**Volcano plots**

Statistical comparisons also offer a volcano plot view.

An example of a volcano plot is shown in figure 29.61.

The volcano plot shows the relationship between the p-values of a statistical test and the fold changes among the samples. The log$_2$ fold changes are plotted on the x-axis, and the $-\log_{10}$ p-values are plotted on the y-axis. Features of interest are typically those in the upper left and right hand corners of the volcano plot, as these have large fold changes (lie far from $x = 0$) and are statistically significant (have large y-values). Please note that p-values smaller than 1.11e-16 are reported as equal to zero, and as a consequence cannot appear on the volcano plot.

Sometimes, the volcano plot will show unexpected pattern looking like "wings", such as the ones highlighted with red arrows in figure 28.32.

These patterns reflect the mathematical relationship between fold change and p-value, which often becomes exposed when there are few replicates and when expression is low in one condition. For example, expression counts for two genes might be (5,5) vs (0,0) and (5,6) vs (0,1). These two genes would appear in the same "wing". Two other genes with expression counts (5,5) vs (0,1) and (5,6) vs (0,1) might be in another "wing".

When working with several samples, it can be useful to make an Expression Browser with all the samples and to open this alongside the Volcano plot. Click a point in the Volcano plot to select
it and then right-click to Select Genes in Other Views. This will select the appropriate row in the expression browser.

**Volcano plot side panel** It is possible to change the type of p-value from the side panel (see below).

The view settings can be adjusted using the **Side Panel**. Under **Graph preferences**, you can adjust the general properties of the volcano plot

- **Lock axes** This will always show the axes even though the plot is zoomed to a detailed level.
- **Frame** Shows a frame around the graph.
- **Show legends** Shows the data legends.
- **Tick type** Determine whether tick lines should be shown outside or inside the frame.
  - Outside
  - Inside
- **Tick lines at** Choosing Major ticks will show a grid behind the graph.
  - None
  - Major ticks
- **Horizontal axis range** Sets the range of the horizontal axis (x axis). Enter a value in Min and Max, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.
- **Vertical axis range** Sets the range of the vertical axis (y axis). Enter a value in Min and Max, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.
Below the general preferences, you find the **Dot properties** and **Text format**, where you can adjust the coloring and appearance of the dots and text.

At the bottom are options for choosing which values to display:

- **P-value type** Selects which type of p-value to use.
- **Label selected points** Chooses whether selected points should be labeled.
- **Lower limit on p-values** Round all p-values smaller than this number to the chosen value (for example, using the default setting, a value of zero will become 1E-16) so even small values can be visualized on a logarithmic scale volcano plot.

Note that if you wish to use the same settings next time you open a volcano plot, you need to save the settings of the **Side Panel**.

### 28.5 Create Heat Map for RNA-Seq

The **Create Heat Map** tool simultaneously clusters samples and features, showing a two dimensional heat map of expression values. Each column corresponds to one sample, and each row corresponds to a feature (a gene or a transcript). The samples and features are both hierarchically clustered. Known metadata about each sample is added as an overlay.
CHAPTER 28. RNA-SEQ

The Create Heat Map for RNA-Seq tool uses the TMM normalization (described in section 28) to make samples comparable, then does a z-score normalization to make features comparable.

28.5.1 Clustering of features and samples

The hierarchical clustering clusters features by the similarity of their expression profiles over the set of samples. It clusters samples by the similarity of expression patterns over their features.

Each clustering has a tree structure that is generated by

1. Letting each feature or sample be a cluster.
2. Calculating pairwise distances between all clusters.
3. Joining the two closest clusters into one new cluster.
4. Iterating 2-3 until there is only one cluster left (which contains all the features or samples).

The tree is drawn so that the distances between clusters are reflected by the lengths of the branches in the tree.

To create a heat map:

Toolbox | RNA-Seq Analysis | Create Heat Map for RNA-Seq

Select at least two expression tracks and click Next.

This will display the wizard shown in figure 28.33. The hierarchical clustering algorithm requires that you specify a distance measure and a cluster linkage. The distance measure is used to specify how distances between two features or samples should be calculated. The cluster linkage specifies how the distance between two clusters, each consisting of a number of features or samples, should be calculated.

Figure 28.33: Parameters for Create Heat Map.

There are three kinds of Distance measures:

- **Euclidean distance** The ordinary distance between two points - the length of the segment connecting them. If $u = (u_1, u_2, \ldots, u_n)$ and $v = (v_1, v_2, \ldots, v_n)$, then the Euclidean
distance between \( u \) and \( v \) is

\[
|u - v| = \sqrt{\sum_{i=1}^{n} (u_i - v_i)^2}.
\]

- **Manhattan distance** The Manhattan distance between two points is the distance measured along axes at right angles. If \( u = (u_1, u_2, \ldots, u_n) \) and \( v = (v_1, v_2, \ldots, v_n) \), then the Manhattan distance between \( u \) and \( v \) is

\[
|u - v| = \sum_{i=1}^{n} |u_i - v_i|.
\]

- **1 - Pearson correlation** The Pearson correlation coefficient between two elements \( x = (x_1, x_2, \ldots, x_n) \) and \( y = (y_1, y_2, \ldots, y_n) \) is defined as

\[
r = \frac{1}{n-1} \sum_{i=1}^{n} \left( \frac{x_i - \bar{x}}{s_x} \right) \left( \frac{y_i - \bar{y}}{s_y} \right)
\]

where \( \bar{x}/\bar{y} \) is the average of values in \( x/y \) and \( s_x/s_y \) is the sample standard deviation of these values. It takes a value \( \in [-1, 1] \). Highly correlated elements have a high absolute value of the Pearson correlation, and elements whose values are un-informative about each other have Pearson correlation 0. Using \( 1 - |\text{Pearson correlation}| \) as distance measure means that elements that are highly correlated will have a short distance between them, and elements that have low correlation will be more distant from each other.

The possible cluster linkages are:

- **Single linkage** The distance between two clusters is computed as the distance between the two closest elements in the two clusters.

- **Average linkage** The distance between two clusters is computed as the average distance between objects from the first cluster and objects from the second cluster. The averaging is performed over all pairs \( (x, y) \), where \( x \) is an object from the first cluster and \( y \) is an object from the second cluster.

- **Complete linkage** The distance between two clusters is computed as the maximal object-to-object distance \( d(x_i, y_j) \), where \( x_i \) comes from the first cluster, and \( y_j \) comes from the second cluster. In other words, the distance between two clusters is computed as the distance between the two farthest objects in the two clusters.

After having selected the distance measure, click **Next** to set up the feature filtering options as shown in figure 28.34.

Genomes usually contain too many features to allow for a meaningful visualization of all genes or transcripts. Clustering hundreds of thousands of features is also very time consuming. Therefore it is recommend to reduce the number of features before clustering and visualization.

There are several different **Filter settings** to filter genes or transcripts:

- **No filtering** Keeps all features.
CHAPTER 28. RNA-SEQ

• Fixed number of features
  - Fixed number of features The given number of features with the highest coefficient of variation (the ratio of the standard deviation to the mean) are kept.
  - Minimum counts in at least one sample Only features with more than this number of counts in at least one sample will be taken into account. Notice that the counts are raw, un-normalized values.

• Filter by statistics Keeps features that are differentially expressed according to the specified cut-offs.
  - Statistical comparison A single statistical comparison track output by the Differential Expression for RNA-Seq tool.
  - Minimum absolute fold change Only features with a higher absolute fold change are kept.
  - Threshold Only features with a lower p-value are kept. It is possible to select which type of p-value to use.

• Specify features Keeps a set of features, as specified by either a feature track or by plain text.
  - Feature track Any genes or transcripts defined in the feature track will be kept.
  - Keep these features A plain text list of feature names. Any white-space characters, and ",", and ";" are accepted as separators.

28.5.2 The heat map view

After the tool completes, a heat map like the one shown in (figure 28.35) is produced. In the heat map each row corresponds to a feature and each column to a sample. The color in the i’th row
and $j$’th column reflects the expression level of feature $i$ in sample $j$ (the color scale can be set in the side panel). The expression values used are normalized log CPM values, see section 28.

There are a number of options to change the appearance of the heat map. At the top of the Side Panel, you find the Heat map group (see figure 28.35).

- **Lock width to window** When you zoom in the heat map, you will per default only zoom in on the vertical level. This is because the width of the heat map is locked to the window. If you uncheck this option, you will zoom both vertically and horizontally. Since you normally have more features than samples, it is useful to lock the width since you then have all the samples in view all the time.

- **Lock height to window** This is the corresponding option for the height. Note that if you check both options, you will not be able to zoom at all, since both the width and the height are fixed.

- **Lock headers and footers** This will ensure that you are always able to see the sample and feature names and the trees when you zoom in.

- **Colors** The expression levels are visualized using a gradient color scheme, where the right side color is used for high expression levels and the left side color is used for low expression levels. You can change the coloring by clicking the box, and you can change the relative coloring of the values by dragging the two knobs on the white slider above.

Below you find the Samples and Features groups. They contain options to show names, color legends, and trees above or below the heat map. The tree options also control the Tree size, including the option of showing the full tree, no matter how much space it will use.

The Metadata group makes it possible to visualize metadata associated with the Expression tracks:
• **Legend font settings** adjusts the label settings.

• **Metadata layers** adds a color bar to the hierarchical sample tree, colored according to the value of a chosen metadata table column.

### 28.6 Create Expression Browser

The **Create Expression Browser** tool makes it possible to inspect gene and transcript expression level counts, annotations and statistics for many samples at the same time.

To run the tool:

1. Toolbox | RNA-Seq Analysis | Create Expression Browser

Select a number of expression tracks, either **Gene level (GE)** or **Transcript level Expression (TE)** tracks but not a combination of both, and click **Next** (see figure 28.36).

![Figure 28.36: Select expression tracks, either GE or TE.](image)

In the second wizard dialog (see figure 28.37), you can decide to add one or more statistical comparisons or an annotation source.

![Figure 28.37: It is optional to provide statistical comparisons and annotation resources.](image)

Statistical comparisons are generated by the Differential Expression for RNA-Seq tool. You can only choose a comparison that was generated by the same kind of expression tracks as the ones you selected in the previous step. This means that when you want to create an expression browser for GE expression levels, you can only input in the second optional step a statistical comparison generated using GE tracks as well.

Annotation resources can be obtained from different sources:
In the majority of cases, annotations are obtained from Gene Ontology consortium at http://geneontology.org/page/download-annotations. Download the *.gz file of your choice from the website on to your computer, and import it in the workbench using the Standard Import tool.

You may have your own annotation data in a spreadsheet. Learn how to import such files here: section K.5.

Annotations can be generated by the "Blast2GO PRO" plugin (see http://www.qiagenbioinformatics.com/plugins/blast2go-pro/ for more information).

Some annotations for human, mouse and rat are also bundled together with Reference Data Sets.

28.6.1 The expression browser

An Expression Browser is shown in figure 28.38.

![Expression browser table when no statistical comparison or annotations resources were provided.](image)

Each row represents a gene or a transcript, defined by its name, the chromosome and the region where it is located, as well as an identifier linking to the relevant online database.

The expression values for each sample or aggregation of samples can be given by total counts, RPKM, TPM or CPM (Counts Per Million). These measurements differ from each other in two key ways:

1. RPKM and TPM measure the number of transcripts whereas total counts and CPM measure the number of reads. The distinction is important because in an RNA-Seq experiment, more reads are typically sequenced from longer transcripts than from shorter ones.

2. RPKM, TPM and CPM are normalized for sequencing-depth so their values are comparable between samples. Total counts is not normalized, so values are not comparable between samples.
How do I get the normalized counts used to calculate fold changes? The CPM expression values are most comparable to the results of the Differential Expression for RNA-Seq tool. However, normalized counts are not used to calculate fold changes; instead the Differential Expression for RNA-Seq tool works by fitting a statistical model (which accounts for differences in sequencing-depth) to raw counts. It is therefore not possible to derive these fold changes from the CPM values by simple algebraic calculations.

It is possible to display the values for individual samples, or for groups of samples as defined by the metadata. Using the drop down menus in the "Grouping" section of the right-hand side setting panel, you can choose to group samples according to up to three metadata layers as shown in figure 28.38.

When individual samples are aggregated, an additional "summary statistic" column can be displayed to give either the mean, the minimum, or the maximum expression value for each group of samples. The table in figure 28.38 shows the mean of the expression values for the first group layer that was selected.

If one or more statistical comparisons are provided, extra columns can be displayed in the table using the "Statistical comparison" section of the Settings panel (figure 28.39). The columns correspond to the different statistical values generated by the Differential Expression for RNA-Seq tool as detailed in section 28.4.4.

If an annotation database is provided, extra columns can be displayed in the table using the "Annotation" section of the Settings panel (figure 28.40). Which columns are available depends on the annotation file used. When using a GO annotation file, the GO biological process column will list for each gene or transcript one or several biological processes. Click on the process name to open the corresponding page on the Consortium for Gene Ontology webpage. It is also possible to access additional online information by clicking on the the PMID, RefSeq, HGNC or UniProt accession number when available.

Select the genes of interest and use the button present at the bottom of the table to highlight the genes in other views (volcano plot for instance) or to copy the genes of interest to a clipboard.

28.7 Create Venn Diagram for RNA-Seq

The **Create Venn Diagram** tool makes it possible to compare the overlap of differentially expressed genes or transcripts in two or more statistical comparison tracks. The genes considered to be differentially expressed can be controlled by setting appropriate p-value and fold change thresholds.

To create the Venn diagram:
CHAPTER 28. RNA-SEQ

Figure 28.40: Expression browser table when a GO annotation file is present.

Toolbox | RNA-Seq Analysis | Create Venn Diagram

Select a number of statistical comparison tracks and click **Next** (see figure 28.41).

In the **Side Panel** to the right, it is possible to adjust the Venn Diagram settings. Under **Layout**, you can adjust the general properties of the plot.

- **Label circles** Toggles the names of the statistical comparison tracks.
- **Show counts** Toggles the display of gene or transcript counts.
- **Area-proportional Venn Diagram** When drawn as a Standard Venn Diagram, circles are drawn with fixed positions and identical size. When drawn in the default Venn Diagram mode, sizes and positions of the circles are adjusted in proportion to the number of overlapping features.
The **Data** side panel group makes it possible to choose the differentially expressed genes or features of interest. The set of statistical comparisons to be compared can be selected using the drop down combo boxes at the top of the group. It is possible to customize the color of a given statistical comparison using the color picker next to the drop down combo box.

- **Minimum absolute fold change** Only genes or transcripts with an absolute fold change higher than the specified threshold are taken into account.
- **Maximum P-value** Only genes or transcripts with a p-value less than the specified threshold will be taken into account. It is possible to select which p-value measure to use.

Finally, the **Text format** group makes it possible to adjust the settings for the count and statistical comparison labels.

### 28.7.1 Venn diagram table view

It is possible to inspect the p-values and fold changes for each gene or transcript individually in the Venn diagram table view (see figure 28.42).

![Venn diagram table view](figure28.42.png)

Figure 28.42: The Venn diagram table view.

Clicking a circle segment in the Venn Diagram plot will select the genes or transcript in the table view. You can then use the "Filter to selection" button in the Table view to only see the selected rows. It is also possible to create a subset list of genes or transcripts using the **Create from selection**.

In the **Side Panel** to the right it is possible to adjust the Table settings. It is possible to adjust the column layout, and select which columns should be included in the table.
28.8 Gene Set Test

The Gene Set Test tool tests whether GO terms are over-represented in a set of differentially expressed genes (input as a statistical comparison track) using a hypergeometric test. The tool will require a GO annotation file that must be previously saved in the Navigation Area of the workbench.

GO annotation files are available from several sources (Blast2Go, GO ontology database). Before import, check that the table does have a GO column, and if not, edit the table to change the relevant column header to GO before import in the workbench using the Standard Import function. For GO annotation files in GAF format, use the option "Force import as type: Gene Ontology Annotation file" from the drop down menu at the bottom of the Standard Import dialog.

RefSeq files are available via the Reference Data Manager, and are saved in the "CLC_Reference" folder in the Navigation Area if you have already downloaded a Reference Data Set.

It is also possible to format a text file of custom annotations into a format the Gene Set Test tool can use (see section K.5.2 and section K.4).

- The file type should be *.csv.
- The values should be comma-separated and in quotation marks.
- The first column should be "Probe Set ID" or one of the other recognized values mentioned in the manual, and the values in the first column must match the feature names in the data exactly.
- The actual annotations should be found in one of the "Gene Ontology"-type columns: Gene Ontology Biological Process, Gene Ontology Cellular Component, Gene Ontology Molecular Function.
- The separator // is used to separate the name of an annotation from its description, and the separator /// is used to separate different annotations from each other. Each annotation should then look like: "AnnotationA_name // AnnotationA description /// AnnotationB_name // AnnotationB description".

This custom annotation file can be imported using the Standard Import functionality.

To start the tool:

Toolbox | RNA-Seq Analysis | Gene Set Test

Select a statistical comparison track (▲) and click Next (see figure 28.43). To run several statistical comparisons at once, use the batch function.

Figure 28.43: Select one statistical comparison.
In the "Annotation testing parameters" dialog, you need to specify a GO annotation file and have several annotation testing options (see figure 28.44).

- **GOA**: Specify a GO annotation file (such as described in the introduction of this section) using the Browse button to the right of the field.

- **GO biological process** Tests for enriched GO biological processes, i.e., a series of events or molecular functions such as "lipid storage" or "chemical homeostasis".

- **GO molecular function** Tests for enriched GO molecular functions. The GO molecular functions of a gene can be such as "retinoic acid receptor activity" or "transcription regulator activity".

- **GO cellular component** Tests for enriched GO cellular component. A GO cellular component ontology describes locations, such as "nuclear inner membrane" or "ubiquitine ligase complex".

- **Exclude computationally inferred GO terms** excludes uncurated GO terms with evidence code IEA, i.e., terms that were automatically curated but not reviewed by a curator.

- **Allow gene name synonyms** allows matching of the gene name with database identifiers and synonyms.

- **Ignore gene name capitalization** ignores capitalization in feature names: a gene called "Dat" in the statistical comparison track will be matched with the one called "dat" in the annotation file when this option is checked. If "Dat" and "dat" are believe to be different genes, the option should be unchecked.

Click Next to access the "Filtering parameters" dialog (see figure 28.45).

Instead of annotating all genes present in the statistical comparison track, it is possible to focus on the subset of genes that are differentially expressed. The filtering parameters allow you to define this subset:

- **Ignore features with mean RPKM below.** Only features where the highest group mean RPKM exceeds this limit will be included in the analysis.
• **Minimum absolute fold change.** Define the minimum absolute fold change value for a feature, and specify whether this fold change should calculated as p-value, FDR p-value or Bonferroni (for a detailed definition of these, see section 29.5.4).

• **Threshold.** Maximum p-value for a feature.

Click **Finish** to Open or Save the file in a specified location of the Navigation Area.

During analysis, a black banner in the left hand side of the workbench warns if duplicate features were found while processing the file. If you get this warning message, consider unchecking the "Ignore gene name capitalization" option.

The output is a table called "GO enrichment analysis" (see figure 28.46). The table is sorted in order of ascending p-values but it can easily be sorted differently, as well as filtered to highlight only the GO terms that are over-represented.

The table lists for each GO term the number and names of Detected Genes, and of DE (Differentially Expressed) Genes. It also provides FDR and Bonferroni-corrected p-values. Note that the p-values provided in the table are meant as a guide, as GO annotations are not strictly independent of each other (for example, "reproduction" is a broad category that encompass a nested set of terms from other categories such as "pheromone biosynthetic process").

29.1 Small RNA analysis

The small RNA analysis tools in CLC Genomics Workbench are designed to facilitate trimming of sequencing reads, counting and annotating of the resulting tags using miRBase or other annotation sources and performing expression analysis of the results. The tools are general and flexible enough to accommodate a variety of data sets and applications within small RNA profiling, including the counting and annotation of both microRNAs and other non-coding RNAs from any organism. Illumina and 454 sequencing platforms are supported.

The annotation part is designed to make special use of the information in miRBase but more general references can be used as well.

There are generally two approaches to the analysis of microRNAs or other smallRNAs: (1) count the different types of small RNAs in the data and compare them to databases of microRNAs or other smallRNAs, or (2) map the small RNAs to an annotated reference genome and count the numbers of reads mapped to regions which have smallRNAs annotated. The approach taken by CLC Genomics Workbench is (1). This approach has the advantage that it does not require an annotated genome for mapping — you can use the sequences in miRBase or any other sequence list of smallRNAs of interest to annotate the small RNAs. In addition, small RNAs that would not have mapped to the genome (e.g. when lacking a high-quality reference genome or if the RNAs have not been transcribed from the host genome) can still be measured and their expression be compared. The methods and tools developed for CLC Genomics Workbench are inspired by the findings and methods described in [Creighton et al., 2009], [Wyman et al., 2009], [Morin et al., 2008] and [Stark et al., 2010].

In the following, the tools for working with small RNAs are described in detail.

29.1.1 Extract and count

First step in the analysis is to import the data (see section 6.3).

The next step is to extract and count the small RNAs to create a small RNA sample that can be used for further analysis (either annotating or analyzing using the expression analysis tools):

Toolbox | Microarray and Small RNA Analysis ( ) | Small RNA Analysis ( ) | Extract and Count ( )

This will open a dialog where you select the sequencing reads that you have imported. Click Next when the sequencing data is listed in the right-hand side of the dialog. Note that if you have several samples, they should be processed separately.

This dialog (see figure 29.1) is where you specify whether the reads should be trimmed for adapter sequences prior to counting. It is often necessary to trim off remainders of adapter
sequences from the reads before counting.

![Figure 29.1: Specifying whether adapter trimming is needed.](image1)

When you click **Next**, you will be able to specify how the trim should be performed as shown in figure **29.2**.

![Figure 29.2: Setting parameters for adapter trim.](image2)

If you have chosen not to trim the reads for adapter sequence, you will see figure **29.3** instead.

The trim options shown in figure **29.2** are the same as described under adapter trim in section **24.2.2**. Please refer to this section for more information.

It should be noted that if you expect to see part of adapters in your reads, you would typically choose **Discard when not found** as the action. By doing this, only reads containing the adapter sequence will be counted as small RNAs in the further analysis. If you have a data set where the adapter may be there or not you would choose **Remove adapter**.

Note that all reads will be trimmed for ambiguity symbols such as N before the adapter trim.

Clicking **Next** allows you to specify additional options regarding trimming and counting as shown in figure **29.3**.

At the top you can choose to **Trim bases** by specifying a number of bases to be removed from either the 3’ or the 5’ end of the reads. Below, you can specify the minimum and maximum lengths of the small RNAs to be counted (this is the length after trimming). The minimum length that can be set is 15 and the maximum is 55.

At the bottom, you can specify the **Minimum sampling count**. This is the number of copies of the small RNAs (tags) that are needed in order to include it in the resulting count table (the small RNA sample). The actual counting is very simple and relies on **perfect match** between the reads...
to be counted together\(^1\). This also means that a count threshold of 1 will include a lot of unique tags as a result of sequencing errors. In order to set the threshold right, the following should be considered:

- If the sample is going to be annotated, annotations may be found for the tags resulting from sequencing errors. This means that there is no negative effect of including tags with a low count in the output.

- When using un-annotated sequences for discovery of novel small RNAs, it may be useful to apply a higher threshold to eliminate the noise from sequencing errors. However, this can be done at a later stage by filtering the sample and creating a sub-set.

- When multiple samples are compared, it is interesting to know if one tag which is abundant in one sample is also found in another, even at a very low number. In this case, it is useful to include the tags with very low counts, since they may become more trustworthy in combination with information from other samples.

- Setting the count threshold higher will reduce the size of the sample produced which will reduce the memory and disk usage when working with the results.

Clicking **Next** allows you to specify the output of the analysis as shown in 29.4.

---

\(^1\)Note that you can identify variants of the same miRNA when annotating the sample (see below).
The options are:

**Create sample** This is the primary result showing all the tags and respective counts (an example is shown in figure 29.5). Each row represents a tag with the actual sequence as the feature ID and columns with **Expression values, Length, and Count**. Expression values and the actual count are based on 100% similarity. The sample can be used in further analysis in the "raw" form, or you can annotate it (see below). The tools for working with the data in the sample are described in section 29.1.4. Note that when small RNA samples are used for setting up and experiment, it is always the Expression values that will be used.

**Create report** This will create a summary report as described below.

**Create list of reads discarded during trimming** This list contains the reads where no adapter was found (when choosing **Discard when not found** as the action).

**Create list of reads excluded from sample** This list contains the reads that passed the trimming but failed to meet the sampling thresholds regarding minimum/maximum length and number of copies.

Figure 29.5: *The tags have been extracted and counted.*

The summary report includes the following information (an example is shown in figure 29.6):

**Trim summary** Shows the following information for each input file:

- Number of reads in the input.
- Average length of the reads in the input.
- Number of reads after trim. The difference between the number of reads in the input and this number will be the number of reads that are discarded by the trim.
- Percentage of the reads that pass the trim.
- Average length after trim. When analyzing miRNAs, you would expect this number to be around 22. If the number is significantly lower or higher, it could indicate that the trim settings are not right. In this case, check that the trim sequence is correct, that

---

2 Note that you can identify variants of the same miRNA when annotating the sample (see below).
the strand is right, and adjust the alignment scores. Sometimes it is preferable to increase the minimum scores to get rid of low-quality reads. The average length after trim could also be somewhat larger than 22 if your sequenced data contains a mixture of miRNA and other (longer) small RNAs.

**Read length before/after trimming** Shows the distribution of read lengths before and after trim. The graph shown in figure 29.6 is typical for miRNA sequencing where the read lengths after trim peaks at 22 bp.

**Trim settings** The trim settings summarized. Note that ambiguity characters will automatically be trimmed.

**Detailed trim results** This is described in the Trim output section 24.2.5.

**Tag counts** The number of tags and two plots showing on the x-axis the counts of tags and on the y-axis the number of tags for which this particular count is observed. The plot is in a zoomed version where only the lower part of the y-axis is shown to make it possible to see the numbers of tags higher counts.

![Figure 29.6: A summary report of the counting.](image)

### 29.1.2 Downloading miRBase

In order to make use of the additional information about mature regions on the precursor miRNAs in miRBase, you need to use the integrated tool to download miRBase rather than downloading it from [http://www.mirbase.org/](http://www.mirbase.org/):

**Toolbox | Microarray and Small RNA | Small RNA Analysis ( ) | Download miRBase ( )**

This will download a sequence list with all the precursor miRNAs including annotations for mature regions. The list can then be selected when annotating the samples with miRBase (see section 29.1.3).
The downloaded version will always be the latest version (it is downloaded from ftp://mirbase.org/pub/mirbase/CURRENT/miRNA.dat.gz). Information on the version number of miRBase is also available in the History of the downloaded sequence list, and when using this for annotation, the annotated samples will also include this information in their History.

**Importing the miRBase data file** You can also import the miRBase data file directly into the Workbench. The file can be downloaded from ftp://mirbase.org/pub/mirbase/CURRENT/miRNA.dat.gz.

In order for the file to be recognized as a miRBase file, you have to select miRBase dat in the Force import as type menu of the Standard Import dialog.

A *.dat file follows the following format:

```
ID cel-let-7
XX
DE Caenorhabditis elegans let-7 stem-loop
XX
FH Key Location/Qualifiers
FH
FT miRNA 17..38
FT /product="cel-let-7-5p"
FT miRNA 60..81
FT /product="cel-let-7-3p"

uaugcaauuu ucuaccuuac cggagacaga acucuucga 99
//
ID cel-lin-4
XX
DE Caenorhabditis elegans lin-4 stem-loop
XX
FH Key Location/Qualifiers
FH
FT miRNA 16..36
FT /product="cel-lin-4-5p"
FT miRNA 55..76
FT /product="cel-lin-4-3p"
XX
SQ Sequence 94 BP; 17 A; 25 C; 26 G; 0 T; 26 other;
augcuuccgg ccguuucccu gagauccucaa gugugagugu acuauuauag cuucacaccu 60
ggccucucgc guaacagaca cgguuugagc agau 94
//
```

**Creating your own miRBase file** If you wish to construct a file yourself to be used as a miRBase file for annotation, this is also possible if you format the file in the same way as the miRBase
data file. In particular, the following needs to be in place:

- The sequences need "miRNA" annotation on the precursor sequences. In the Workbench, you can add a miRNA annotation by selecting a region and right click to Add Annotation. You should have a max 2 miRNA annotations per precursor sequences. Matches to first miRNA annotation are counting in 5’ column. Matches to second miRNA annotation are counted as 3’ matches.

- If you have sequence list containing sequences from multiple species, the Latin name of the sequences should be set. This is used in the annotation dialog (see section 29.1.3) where you can select the species. If the Latin name is not set, the dialog will show "N/A".

Once you have created the file, it has to be imported as described above.

### 29.1.3 Annotating and merging small RNA samples

The small RNA sample produced when counting the tags (see section 29.1.1) can be enriched by CLC Genomics Workbench by comparing the tag sequences with annotation resources such as miRBase and other small RNA annotation sources. Note that the annotation can also be performed on an experiment, set up from small RNA samples (see section 29.2.1).

Besides adding annotations to known small RNAs in the sample, it is also possible to merge variants of the same small RNA to get a cumulative count. When initially counting the tags, the Workbench requires that the trimmed reads are identical for them to be counted as the same tag. However, you will often see different variants of the same miRNA in a sample, and it is useful to be able to count these together. This is also possible using the tool to annotate and merge samples.

This will open a dialog where you select the small RNA samples to be annotated. Note that if you have included several samples, they will be processed separately but summarized in one report providing a good overview of all samples. You can also input Experiments (see section 29.2.1) created from small RNA samples. Click Next when the data is listed in the right-hand side of the dialog.

This dialog (figure 29.7) is where you define the annotation resources to be used.

There are two ways of providing annotation sources:

- Downloading miRBase using the integrated download tool (explained in section 29.1.2).

- Importing a list of sequences, e.g. from a fasta file. This could be from Ensembl, e.g. ftp://ftp.ensembl.org/pub/release-57/fasta/homo_sapiens/ncrna/Homo_sapiens.GRCh37.57.ncrna.fa.gz or from ncRNA.org: http://togodb.biosciencedbc.jp/togodb/view/frnadb_summary.

**Note:** We recommend using the integrated download tool to import miRBase. Although it is possible to import it as a fasta file, the same options with regards to species will not be available if you import from a file.
The downloaded miRBase file contains all precursor sequences from the latest version of miRBase [http://www.mirbase.org/] including annotations defining the mature regions (see an example in figure 29.8).

This means that it is possible to have a more fine-grained classification of the tags using miRBase compared to a simple fasta file resource containing the full precursor sequence. This is the reason why the miRBase annotation source is specified separately in figure 29.7.

At the bottom of the dialog, you can specify whether miRBase should be prioritized over the additional annotation resource. The prioritization is explained in detail later in this section. To prioritize one over the other can be useful when there is redundant information (e.g. if you have an additional source that also contains all the miRNAs from miRBase and you prefer the miRBase annotations when possible).

When you click Next, you will be able to choose which species from miRBase should be used and in which order (see figure 29.9). Note that if you have not selected a miRBase annotation source, you will go directly to the next step shown in figure 29.10.

To the left, you see the list of species in miRBase. This list is dynamically created based on the information in the miRBase file. Using the arrow button (↑) you can add species to the right-hand panel. The order of the species is important since the tags are annotated iteratively based on the order specified here. This means that in the example in figure 29.9, a human miRNA will
be preferred over mouse, even if they are identical in sequence (the prioritization is elaborated below). The up and down arrows (↑)/ (↓) can be used to change the order of species.

When you click **Next**, you will be able to specify how the alignment of the tags against the annotation sources should be performed (see figure 29.10).

---

The panel at the top is active only if you have chosen to annotate with miRBase. It is used to define the requirements to the alignment of a read for it to be counted as a 3’ or 5’ mature region (previously referred to as mature and mature*) tag:

- **Additional upstream bases** This defines how many bases the tag is allowed to extend the annotated mature region at the 5’ end and still be categorized as mature.

- **Additional downstream bases** This defines how many bases the tag is allowed to extend the annotated mature region at the 3’ end and still be categorized as mature.

- **Missing upstream bases** This defines how many bases the tag is allowed to miss at the 5’ end compared to the annotated mature region and still be categorized as mature.

- **Missing downstream bases** This defines how many bases the tag is allowed to miss at the 3’ end compared to the annotated mature region and still be categorized as mature.

At the bottom of the dialog you can specify the **Maximum mismatches** (default value is 2). Finally, you can choose whether the tags should be aligned against both strands of the reference or only the positive strand. Usually it is only necessary to align against the positive strand.
At this point, a more elaborate explanation of the annotation algorithm is needed. The short read mapping algorithm in the CLC Genomics Workbench is used to map all the tags to the reference sequences which comprise the full precursor sequences from miRBase and the sequence lists chosen as additional resources. The mapping is done in several rounds: the first round is done requiring a perfect match, the second allowing one mismatch, the third allowing two mismatches etc. No gaps are allowed. The number of rounds depend on the number of mismatches allowed (by default 2, which means 3 rounds of read mapping as in figure 29.10).

After each round of mapping, the tags that are mapped will be removed from the list of tags that continue to the next round. This means that a tag mapping with perfect match in the first round will not be considered for the subsequent one-mismatch round of mapping.

Note: If there are mismatches in the read, there will be a limitation on how short reads can be mapped:

- A minimum read length of 17 nucleotides is required when the read contains one mismatch.
- A minimum read length of 21 nucleotides is required when the read contains two mismatches.
- A minimum read length of 25 nucleotides is required when the read contains three mismatches.

Following the mapping, the tags are classified into the following categories according to where they match.

- Mature 5’ exact
- Mature 5’ super
- Mature 5’ sub
- Mature 5’ sub/super
- Mature 3’ exact
- Mature 3’ super
- Mature 3’ sub
- Mature 3’ sub/super
- Precursor
- Other

All these categories except Other refer to hits in miRBase. For hits on mirBase sequences we distinguish between where on the sequences the tags match. The mirBase sequences may have up to two mature micro RNAs annotated. We refer to a mature miRNA that is located closer (or equally close) to the 5’ end than to the 3’ end as ‘Mature 5’’. A mature miRNA that is located closer to the 3’ end is referred to as ‘Mature 3’’. Exact means that the tag matches exactly to the annotated mature 5’ or 3’ region; Sub means that the observed tag is shorter than the annotated mature 5’ or mature 3’; super means that the observed tag is longer than the annotated mature
5’ or mature 3’. The combination sub/super means that the observed tag extends the annotation in one end and is shorter at the other end. Precursor means that the tag matches on a mirBase sequence, but not within the extended annotated mature region(s). These are defined by the "mature length variants (IsomiRs)" parameters in the "specify match parameters" wizard step (by default these parameters are set to 2 which means that reads that are at most 2 bases too long or too short relative to the annotated mature region are all considered mature hits). The Other category is for hits in the other resources (the information about resource is also shown in the output).

An example of an alignment is shown in figure 29.11 using the same alignment settings as in figure 29.10.

The two tags at the top are both classified as mature 5’ super because they cover and extend beyond the annotated mature 5’ RNA. The third tag is identical to the annotated mature 5’.

If a tag has several hits, the list above is used for prioritization. This means that for example, a Mature 5’ sub is preferred over a Mature 3’ exact. Note that if miRBase was chosen as lowest priority (figure 29.7), the Other category will be at the top of the list. All tags mapping to a miRBase reference without qualifying to any of the mature 5’ and mature 3’ types will be typed as Other. Also note that if a tag has several hits to references with the same priority (e.g. the tag matches the mature regions of two different miRBase sequences) it will be annotated with all these sequences. In the report we refer to these tags as ‘ambiguously annotated’.

In case you have selected more than one species for miRBase annotation (e.g. Homo Sapiens and Mus Musculus) the following rules for adding annotations apply:

1. If a tag has hits with the same priority for both species, the annotation for the top-prioritized species will be added.
2. Read category priority is stronger than species category priority: If a read is a higher priority match for a mouse miRBase sequence than it is for a human miRBase sequence the annotation for the mouse will be used.
Clicking **Next** allows you to specify the output of the analysis as shown in 29.12.

![Image of output options dialog box](image)

**Figure 29.12: Output options.**

The options are:

**Create unannotated sample** All the tags where no hit was found in the annotation source are included in the unannotated sample. This sample can be used for investigating novel miRNAs, see section 29.1.5. No extra information is added, so this is just a subset of the input sample.

**Create annotated sample** This will create a sample as described in section 29.1.4. In this sample, the following columns have been added to the counts.

- **Name** This is the name of the annotation sequence in the annotation source. For miRBase, it will be the names of the miRNAs (e.g. let-7g or mir-147), and for other source, it will be the name of the sequence.

- **Resource** This is the source of the annotation, either miRBase (in which case the species name will be shown) or other sources (e.g. Homo_sapiens.GRCh37.57.ncrna).

- **Match type** The match type can be exact or variant (with mismatches) of the following types:
  - Mature 5’
  - Mature 5’ super
  - Mature 5’ sub
  - Mature 5’ sub/super
  - Mature 3’
  - Mature 3’ super
  - Mature 3’ sub
  - Mature 3’ sub/super
  - Other

- **Mismatches** The number of mismatches.
Note that if a tag has two equally prioritized hits, they will be shown with // between the names. This could be e.g. two precursor sequences sharing the same mature sequence (also see the sample grouped on mature below).

Create grouped sample, grouping by Precursor/Reference This will create a sample as described in section 29.1.4. All variants of the same reference sequence will be merged to create one expression value for all.

Expression values. The expression value can be changed at the bottom of the table. The default is to use the counts in the mature 5’ column.

Name. The name of the reference. For miRBase this will then be the name of the precursor.

Resource. The name of the resource that the reference comes from.

Exact mature 5’. The number of exact mature 5’ reads.

Mature 5’. The number of all mature 5’ reads including sub, super and variants.

Unique exact mature 5’. In cases where one tag has several hits (as denoted by the // in the ungrouped annotated sample as described above), the counts are distributed evenly across the references. The difference between Exact mature 5’ and Unique exact mature 5’ is that the latter only includes reads that are unique to this reference.

Unique mature 5’. Same as above but for all mature 5’s, including sub, super and variants.

Exact mature 3’. Same as above, but for mature 3’.

Mature 3’. Same as above, but for mature 3’.

Unique exact mature 3’. Same as above, but for mature 3’.

Unique mature 3’. Same as above, but for mature 3’.

Exact other. Exact matches in miRBase sequences, but outside annotated mature regions.

Other. All matches in miRBase sequences, but outside annotated mature regions, including variants.

Total. The total number of tags mapped and classified to the precursor/reference sequence.

Note that, for non-miRBase sequences, the counts are collected in the ‘Mature 5’ columns: ‘Exact mature 5’ (number reads that map to the sequence without mismatches), ‘Mature 5’ (number reads that map to the sequence, including those with mismatches), ‘Unique exact mature 5’ (number reads that map uniquely to the sequence without mismatches) and ‘Unique mature 5’ (number reads that map uniquely to the sequence, including those with mismatches).

Create grouped sample, grouping by Mature This will create a sample as described in section 29.1.4. This is also a grouped sample, but in addition to grouping based on the same reference sequence, the tags in this sample are grouped on the same mature 5’. This means that two precursor variants of the same mature 5’ miRNA are merged. For precursor miRNAs that have both a 5’ and a 3’, we group on both 5’ mature and 3’ mature. For these miRNAs you will see two rows in the grouped on mature output table, one with the 5’ mature sequence as feature ID and one with the 3’ mature sequence as feature ID. The ‘Match type’ column indicates whether the feature ID is 5’ or 3’ mature. Note that it is only possible to create this sample when using miRBase as annotation resource (because the Workbench has a special interpretation of the miRBase annotations for mature as
described previously). To find identical mature 5’ miRNAs, the Workbench compares all the mature 5’ sequences and when they are identical, they are merged. The names of the precursor sequences merged are all shown in the table.

**Expression values.** The expression value can be changed at the bottom of the table. The default is to use the counts in the mature 5’ column.

**Name.** The name of the reference. When several precursor sequences have been merged, all the names will be shown separated by //.

**Resource.** The species of the reference.

**Exact mature 5’**. The number of exact mature 5’ reads.

**Mature 5’**. The number of all mature 5’ reads including sub, super and variants.

**Unique exact mature 5’**. In cases where one tag has several hits (as denoted by the // in the ungrouped annotated sample as described above), the counts are distributed evenly across the references. The difference between Exact mature 5’ and Unique exact mature 5’ is that the latter only includes reads that are unique to one of the precursor sequences that are represented under this mature 5’ sequence.

**Unique mature 5’**. Same as above but for all mature 5’s, including sub, super and variants.

**Create report.** A summary report described below.

The summary report includes the following information (an example is shown in figure 29.13):

**Summary** Shows the following information for each input sample:

- Number of small RNAs(tags) in the input.
- Number of annotated tags (number and percentage).
- Number of ambiguously annotated tags (number and percentage).
- Number of reads in the sample (one tag can represent several reads)
- Number of annotated reads (number and percentage).
- Number of ambiguously annotated reads (number and percentage).

**Resources** Shows how many matches were found in each resource:

- Number of sequences in the resource.
- Number of sequences where a match was found (i.e. this sequence has been observed at least once in the sequencing data).

**Reads** Shows the number of reads that fall into different categories (there is one table per input sample). On the left hand side are the annotation resources. For each resource, the count and percentage of reads in that category are shown. Note that the percentage are relative to the overall categories (e.g. the miRBase reads are a percentage of all the annotated reads, not all reads). This is information is shown for each mismatch level.

**Small RNAs** Similar numbers as for the reads but this time for each small RNA tag and without mismatch differentiation.
Read count proportions A histogram showing, for each interval of read counts, the proportion of annotated (respectively, unannotated) small RNAs with a read count in that interval. Annotated small RNAs may be expected to be associated with higher counts, since the most abundant small RNAs are likely to be known already.

Annotations (miRBase) Shows an overview table for classifications of the number of reads that fall in the miRBase categories for each species selected.

Annotations (Other) Shows an overview table with read numbers for total, exact match and mutant variants for each of the other annotation resources.

An example of the results table is shown at the bottom of figure 29.14.

In the upper part of the figure, you can see two tables showing the imported miRBase file (opened twice for illustration purpose). This example has been included to illustrate the logic behind the order in which the resources are listed. If you look at the results table found at the bottom of the figure, you will see that in the Resource column, Mus musculus is listed before Homo sapiens in the first row and in the second row Homo sapiens is listed before Mus musculus. The
rationale behind this can be seen from the two other tables if you look at the accession numbers. If you filter only to include Homo sapiens and Mus musculus RNAs, and sort on the "name" column, you can see that for mir-130b (Mus musculus/Homo sapiens), the miRBase number of the mouse RNA is smaller than the miRBase number of the human RNA. Conversely, for mir-495 (Homo sapiens/Mus musculus), the number is smaller in the human case.

29.1.4 Working with the small RNA sample

Generally speaking, the small RNA sample comes in two variants:

- The un-grouped sample, either as it comes directly from the Extract and Count (extract and count) or when it has been annotated. In this sample, there is one row per tag, and the feature ID is the tag sequence.

- The grouped sample created using the Annotate and Merge Counts (annotate and merge counts) tool. In this sample, each row represents several tags grouped by a common Mature or Precursor miRNA or other reference.

Below, these two kinds of samples are described in further detail. Note that for both samples, filtering and sorting can be applied, see section 3.3.

The ungrouped sample

An example of an ungrouped annotated sample is shown in figure 29.15.
CHAPTER 29. MICROARRAY AND SMALL RNA ANALYSIS

By selecting one or more rows in the table, the buttons at the bottom of the view can be used to extract sequences from the table:

Extract Reads This will extract the original sequencing reads that contributed to this tag. Figure 29.16 shows an example of such a read. The reads include trim annotations (for use when inspecting and double-checking the results of trimming). Note that if these reads are used for read mapping, the trimmed part of the read will automatically be removed. If all rows in the sample are selected and extracted, the sequence list would be the same as the input except for the reads that did not meet the adapter trim settings and the sampling thresholds (tag length and number of copies).

Extract Trimmed Reads The same as above, except that the trimmed part has been removed.

Extract Small RNAs This will extract only one copy of each tag.

Note that for all these, you will be able to determine whether a list of DNA or RNA sequences should be produced (when working within the CLC Genomics Workbench environment, this only effects the RNA folding tools).

The button Create Sample from Selection can be used to create a new sample based on the tags that are selected. This can be useful in combination with filtering and sorting.

The grouped sample

An example of a grouped annotated sample is shown in figure 29.17.

The contents of the table are explained in section 29.1.3. In this section, we focus on the tools available for working with the sample.

By selecting one or more rows in the table, the buttons at the bottom of the view become active:
CHAPTER 29. MICROARRAY AND SMALL RNA ANALYSIS

29.1.5 Exploring novel miRNAs

One way of doing this would be to identify interesting tags based on their counts (typically you would be interested in pursuing tags with not too low counts in order to avoid wasting efforts on tags based on reads with sequencing errors), Extract Small RNAs ( ), and use this list of tags as input to Map Reads to Reference ( ) using the genome as reference. You could then examine where the reads match, and for reads that map in otherwise unannotated regions you could select a region around the match and create a subsequence from this. The subsequence could be folded and examined to see whether the secondary structure was in agreement with the expected hairpin-type structure for miRNAs. The CLC Genomics Workbench is able to analyze expression data produced on microarray platforms and high-throughput sequencing platforms (also known as Next-Generation Sequencing platforms).

The CLC Genomics Workbench provides tools for performing quality control of the data, transformation and normalization, statistical analysis to measure differential expression and annotation-based tests. A number of visualization tools such as volcano plots, MA plots, scatter plots, box plots, and heat maps are used to aid the interpretation of the results.
29.2 Experimental design

In order to make full use of the various tools for interpreting expression data, you need to know the central concepts behind the way the data is organized in the CLC Genomics Workbench.

The first piece of data you are faced with is the sample. In the Workbench, a sample contains the expression values from either one array or from sequencing data of one sample.

Note that the calculation of expression levels based on the raw sequence data is described in section 28.1 and section 29.1.

See more below on how to get your expression data into the Workbench as samples in section K.

In a sample, there is a number of features, usually genes, and their associated expression levels.

To analyze differential expression, you need to tell the workbench how the samples are related. This is done by setting up an experiment. An experiment is essentially a set of samples which are grouped. By creating an experiment defining the relationship between the samples, it becomes possible to do statistical analysis to investigate differential expression between the groups. The Experiment is also used to accumulate calculations like t-tests and clustering because this information is closely related to the grouping of the samples.

29.2.1 Setting up an experiment

To set up an experiment:
Select the samples that you wish to use by double-clicking or selecting and pressing the Add button (see figure 29.19).

Clicking Next shows the dialog in figure 29.20.

Here you define the experiment type and the number of groups in the experiment.

The options are:

- **Experiment.** At the top you can select a two-group experiment, and below you can select a multi-group experiment and define the number of groups.

  Note that you can also specify if the samples are paired. Pairing is relevant if you have samples from the same individual under different conditions, e.g. before and after treatment, or at times 0, 2, and 4 hours after treatment. In this case statistical analysis becomes more efficient if effects of the individuals are taken into account, and comparisons are carried out not simply by considering raw group means but by considering these corrected for effects of the individual. If Paired is selected, a paired rather than a standard t-test
will be carried out for two group comparisons. For multiple group comparisons a repeated 
measures rather than a standard ANOVA will be used.

- **Expression values.** If you choose to **Set new expression value** you can choose between 
  the following options depending on whether you look at the gene or transcript level:

  - **Genes: Unique exon reads.** The number of reads that match uniquely to the exons 
    (including the exon-exon and exon-intron junctions).
  
  - **Genes: Unique gene reads.** This is the number of reads that match uniquely to the 
    gene.
  
  - **Genes: Total exon reads.** Number of reads mapped to this gene that fall entirely 
    within an exon or in exon-exon or exon-intron junctions. As for the "Total gene reads" 
    this includes both uniquely mapped reads and reads with multiple matches that were 
    assigned to an exon of this gene.
  
  - **Genes: Total gene reads.** This is all the reads that are mapped to this gene, i.e., both 
    reads that map uniquely to the gene and reads that matched to more positions in the 
    reference (but fewer than the "Maximum number of hits for a read" parameter) which 
    were assigned to this gene.
  
  - **Genes: RPKM.** This is the expression value measured in RPKM [Mortazavi et al., 
    2008]:
    \[
    \text{RPKM} = \frac{\text{mapped reads (millions)} \times \text{exon length (KB)}}{\text{total exon reads}}
    \]
    See exact definition below. Even if you have chosen the RPKM values to be used in the 
    **Expression values** column, they will also be stored in a separate column. This is useful to store the RPKM if you switch 
    the expression measure. See more in section 28.1.4.

  - **Transcripts: Unique transcript reads.** This is the number of reads in the mapping 
    for the gene that are uniquely assignable to the transcript. This number is calculated 
    after the reads have been mapped and both single and multi-hit reads from the read 
    mapping may be unique transcript reads.
  
  - **Transcripts: Total transcript reads.** Once the "Unique transcript read’s" have been 
    identified and their counts calculated for each transcript, the remaining (non-unique) 
    transcript reads are assigned randomly to one of the transcripts to which they match. 
    The "Total transcript reads" counts are the total number of reads that are assigned 
    to the transcript once this random assignment has been done. As for the random 
    assignment of reads among genes, the random assignment of reads within a gene but 
    among transcripts, is done proportionally to the "unique transcript counts" normalized 
    by transcript length, that is, using the RPKM. Unique transcript counts of 0 are not 
    replaced by 1 for this proportional assignment of non-unique reads among transcripts.
  
  - **Transcripts: RPKM.** The RPKM value for the transcript, that is, the number of reads 
    assigned to the transcript divided by the transcript length and normalized by "Mapped 
    reads" (see below).

Clicking **Next** shows the dialog in figure 29.21.

Depending on the number of groups selected in figure 29.20, you will see a list of groups with 
text fields where you can enter an appropriate name for that group.

For multi-group experiments, if you find out that you have too many groups, click the **Delete** button. If you need more groups, simply click **Add New Group**.

Click **Next** when you have named the groups, and you will see figure 29.22.
This is where you define which group the individual sample belongs to. Simply select one or more samples (by clicking and dragging the mouse), right-click (Ctrl-click on Mac) and select the appropriate group.

Note that the samples are sorted alphabetically based on their names.

If you have chosen Paired in figure 29.20, there will be an extra column where you define which samples belong together. Just as when defining the group membership, you select one or more samples, right-click in the pairing column and select a pair.

Click Finish to start the tool.

29.2.2 Organization of the experiment table

The resulting experiment includes all the expression values and other information from the samples (the values are copied - the original samples are not affected and can thus be deleted with no effect on the experiment). In addition it includes a number of summaries of the values across all, or a subset of, the samples for each feature. Which values are included is described in the sections below.

When you open it, it is shown in the experiment table (see figure 29.23).

For a general introduction to table features like sorting and filtering, see section 3.3.

Unlike other tables in CLC Genomics Workbench, the experiment table has a hierarchical grouping
of the columns. This is done to reflect the structure of the data in the experiment. The Side Panel is divided into a number of groups corresponding to the structure of the table. These are described below. Note that you can customize and save the settings of the Side Panel (see section 4.6).

Whenever you perform analyses like normalization, transformation, statistical analysis etc, new columns will be added to the experiment. You can at any time Export all the data in the experiment in csv or Excel format or Copy the full table or parts of it.

### Column width

There are two options to specify the width of the columns and also the entire table:

- **Automatic**. This will fit the entire table into the width of the view. This is useful if you only have a few columns.

- **Manual**. This will adjust the width of all columns evenly, and it will make the table as wide as it needs to be to display all the columns. This is useful if you have many columns. In this case there will be a scroll bar at the bottom, and you can manually adjust the width by dragging the column separators.

### Experiment level

The rest of the Side Panel is devoted to different levels of information on the values in the experiment. The experiment part contains a number of columns that, for each feature ID, provide summaries of the values across all the samples in the experiment (see figure 29.24).

Initially, it has one header for the whole Experiment:

- **Range (original values)**. The ‘Range’ column contains the difference between the highest and the lowest expression value for the feature over all the samples. If a feature has the value NaN in one or more of the samples the range value is NaN.

- **IQR (original values)**. The ‘IQR’ column contains the inter-quantile range of the values for a feature across the samples, that is, the difference between the 75 %-ile value and the 25 %-ile value. For the IQR values, only the numeric values are considered when percentiles
are calculated (that is, NaN and +Inf or -Inf values are ignored), and if there are fewer than four samples with numeric values for a feature, the IQR is set to be the difference between the highest and lowest of these.

- **Difference (original values).** For a two-group experiment the 'Difference' column contains the difference between the mean of the expression values across the samples assigned to group 2 and the mean of the expression values across the samples assigned to group 1. Thus, if the mean expression level in group 2 is higher than that of group 1 the 'Difference' is positive, and if it is lower the 'Difference' is negative. For experiments with more than two groups the 'Difference' contains the difference between the maximum and minimum of the mean expression values of the groups, multiplied by -1 if the group with the maximum mean expression value occurs before the group with the minimum mean expression value (with the ordering: group 1, group 2, ...).

- **Fold Change (original values).** For a two-group experiment the 'Fold Change' tells you how many times bigger the mean expression value in group 2 is relative to that of group 1. If the mean expression value in group 2 is bigger than that in group 1 this value is the mean expression value in group 2 divided by that in group 1. If the mean expression value in group 2 is smaller than that in group 1 the fold change is the mean expression value in group 1 divided by that in group 2 with a negative sign. Thus, if the mean expression levels in group 1 and group 2 are 10 and 50 respectively, the fold change is 5, and if the mean expression levels in group 1 and group 2 are 50 and 10 respectively, the fold change is -5. Entries of plus or minus infinity in the 'Fold Change' columns of the Experiment area represent those where one of the expression values in the calculation is a 0. For experiments with more than two groups, the 'Fold Change' column contains the ratio of the maximum of the mean expression values of the groups to the minimum of the mean expression values of the groups, multiplied by -1 if the group with the maximum mean expression value occurs before the group with the minimum mean expression value (with the ordering: group 1, group 2, ...).

Thus, the sign of the values in the 'Difference' and 'Fold change' columns give the direction of the trend across the groups, going from group 1 to group 2, etc.

If the samples used are Affymetrix GeneChips samples and have 'Present calls' there will also be a 'Total present count' column containing the number of present calls for all samples.

The columns under the 'Experiment' header are useful for filtering purposes, e.g. you may wish to ignore features that differ too little in expression levels to be confirmed e.g. by qPCR by filtering on the values in the 'Difference', 'IQR' or 'Fold Change' columns or you may wish to ignore features that do not differ at all by filtering on the 'Range' column.
If you have performed normalization or transformation (see sections 29.3.3 and 29.3.2, respectively), the IQR of the normalized and transformed values will also appear. Also, if you later choose to transform or normalize your experiment, columns will be added for the transformed or normalized values.

**Note!** It is very common to filter features on fold change values in expression analysis and fold change values are also used in volcano plots, see section 29.5.5. There are different definitions of 'Fold Change' in the literature. The definition that is used typically depends on the original scale of the data that is analyzed. For data whose original scale is not the log scale the standard definition is the ratio of the group means [Tusher et al., 2001]. This is the value you find in the ‘Fold Change’ column of the experiment. However, for data whose original is the log scale, the difference of the mean expression levels is sometimes referred to as the fold change [Guo et al., 2006], and if you want to filter on fold change for these data you should filter on the values in the ‘Difference’ column. Your data’s original scale will e.g. be the log scale if you have imported Affymetrix expression values which have been created by running the RMA algorithm on the probe-intensities.

**Analysis level**

The results of each statistical test performed are in the columns listed in this area. In the table, a heading is given for each test. Information about the results of statistical tests are described in the statistical analysis section (see section 29.5).

An example of Analysis level settings is shown in figure 29.25.

![Figure 29.25: An example of columns available under the Analysis level section.](image)

**Note:** Some column names here are the same as ones under the Experiment level, but the results here are from statistical tests, while those under the Experiment level section are calculations carried out directly on the expression levels.
**Annotation level**

If your experiment is annotated (see section 29.2.3), the annotations will be listed in the **Annotation level** group as shown in figure 29.26.

![Figure 29.26: An annotated experiment.](image)

In order to avoid too much detail and cluttering the table, only a few of the columns are shown per default.

Note that if you wish a different set of annotations to be displayed each time you open an experiment, you need to save the settings of the **Side Panel** (see section 4.6).

**Group level**

At the group level, you can show/hide entire groups (**Heart** and **Diaphragm** in figure 29.23). This will show/hide everything under the group’s header. Furthermore, you can show/hide group-level information like the group means and present count within a group. If you have performed normalization or transformation (see sections 29.3.3 and 29.3.2, respectively), the means of the normalized and transformed values will also appear.

An example is shown in figure 29.27.

![Figure 29.27: Group level.](image)
**Sample level**

In this part of the side panel, you can control which columns to be displayed for each sample. Initially this is the all the columns in the samples.

If you have performed normalization or transformation (see sections 29.3.3 and 29.3.2, respectively), the normalized and transformed values will also appear.

An example is shown in figure 29.28.

![Sample level when transformation and normalization has been performed.](image)

**Creating a sub-experiment from a selection**

If you have identified a list of genes that you believe are differentially expressed, you can create a subset of the experiment. (Note that the filtering and sorting may come in handy in this situation, see section 3.3).

To create a sub-experiment, first select the relevant features (rows). If you have applied a filter and wish to select all the visible features, press Ctrl + A (⌘ + A on Mac). Next, press the **Create Experiment from Selection** button at the bottom of the table (see figure 29.29).

![Create a subset of the experiment by clicking the button at the bottom of the experiment table.](image)

**Downloading sequences from the experiment table**

If your experiment is annotated, you will be able to download the GenBank sequence for features which have a GenBank accession number in the ‘Public identifier tag’ annotation column. To do
this, select a number of features (rows) in the experiment and then click Download Sequence (see figure 29.30).

Figure 29.30: Select sequences and press the download button.

This will open a dialog where you specify where the sequences should be saved. You can learn more about opening and viewing sequences in chapter 11. You can now use the downloaded sequences for further analysis in the Workbench.

### 29.2.3 Adding annotations to an experiment

Annotation files provide additional information about each feature. This information could be which GO categories the protein belongs to, which pathways, various transcript and protein identifiers etc. See section K for information about the different annotation file formats that are supported CLC Genomics Workbench.

The annotation file can be imported into the Workbench and will get a special icon ( ). See an overview of annotation formats supported by CLC Genomics Workbench in section K. In order to associate an annotation file with an experiment, either select the annotation file when you set up the experiment (see section 29.2.1), or click:

Toolbox | Microarray and Small RNA Analysis ( ) | Annotation Test | Add Annotations ( )

Select the experiment ( ) and the annotation file ( ) and click Finish. You will now be able to see the annotations in the experiment as described in section 29.2.2. You can also add annotations by pressing the Add Annotations ( ) button at the bottom of the table (see figure 29.31).

Figure 29.31: Adding annotations by clicking the button at the bottom of the experiment table.

This will bring up a dialog where you can select the annotation file that you have imported together with the experiment you wish to annotate. Click Next to specify settings as shown in figure 29.32).

In this dialog, you can specify how to match the annotations to the features in the sample. The
Figure 29.32: Choosing how to match annotations with samples.

Workbench looks at the columns in the annotation file and lets you choose which column that should be used for matching to the feature IDs in the experimental data (experiment or sample) as well as for the annotations. Usually the default is right, but for some annotation files, you need to select another column.

Some annotation files have leading zeros in the identifier which you can remove by checking the Remove leading zeros box.

Note! Existing annotations on the experiment will be overwritten.

29.2.4 Scatter plot view of an experiment

At the bottom of the experiment table, you can switch between different views of the experiment (see figure 29.33).

One of the views is the Scatter Plot. The scatter plot can be adjusted to show e.g. the group means for two groups (see more about how to adjust this below).

An example of a scatter plot is shown in figure 29.34.

In the Side Panel to the left, there are a number of options to adjust this view. Under Graph preferences, you can adjust the general properties of the scatter plot:

- **Lock axes** This will always show the axes even though the plot is zoomed to a detailed level.
- **Frame** Shows a frame around the graph.
- **Show legends** Shows the data legends.
- **Tick type** Determine whether tick lines should be shown outside or inside the frame.
  - Outside
  - Inside
- **Tick lines at** Choosing Major ticks will show a grid behind the graph.
Figure 29.34: A scatter plot of group means for two groups (transformed expression values).

- None
- Major ticks

- **Horizontal axis range** Sets the range of the horizontal axis (x axis). Enter a value in Min and Max, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.

- **Vertical axis range** Sets the range of the vertical axis (y axis). Enter a value in Min and Max, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.

- **Draw x = y axis**. This will draw a diagonal line across the plot. This line is shown per default.

- **Line width**
  - Thin
  - Medium
  - Wide

- **Line type**
  - None
  - Line
  - Long dash
  - Short dash

- **Line color**. Allows you to choose between many different colors. Click the color box to select a color.

- **Show Pearson correlation**. When checked, the Pearson correlation coefficient (r) is displayed on the plot.
Below the general preferences, you find the **Dot properties** preferences, where you can adjust coloring and appearance of the dots:

- **Dot type**
  - None
  - Cross
  - Plus
  - Square
  - Diamond
  - Circle
  - Triangle
  - Reverse triangle
  - Dot

- **Dot color.** Allows you to choose between many different colors. Click the color box to select a color.

Finally, the group at the bottom - **Values to plot** - is where you choose the values to be displayed in the graph. The default for a two-group experiment is to plot the group means.

Note that if you wish to use the same settings next time you open a scatter plot, you need to save the settings of the **Side Panel** (see section 4.6).

### 29.2.5 Cross-view selections

There are a number of different ways of looking at an experiment as shown in figure 29.35).

![Figure 29.35: An experiment can be viewed in several ways.](image)

Beside the **Experiment table** (__) which is the default view, the views are: **Scatter plot** ( ), **Volcano plot** ( ) and the **Heat map** ( ). By pressing and holding the Ctrl ( on Mac) button while you click one of the view buttons in figure 29.35, you can make a split view. This will make it possible to see e.g. the experiment table in one view and the volcano plot in another view.

An example of such a split view is shown in figure 29.36.

Selections are shared between all these different views of an experiment. This means that if you select a number of rows in the table, the corresponding dots in the scatter plot, volcano plot or heatmap will also be selected. The selection can be made in any view, also the heat map, and all other open views will reflect the selection.

A common use of the split views is where you have an experiment and have performed a statistical analysis. You filter the experiment to identify all genes that have an FDR corrected p-value below
0.05 and a fold change for the test above say, 2. You can select all the rows in the experiment table satisfying these filters by holding down the Cntrl button and clicking ‘a’. If you have a split view of the experiment and the volcano plot all points in the volcano plot corresponding to the selected features will be red. Note that the volcano plot allows two sets of values in the columns under the test you are considering to be displayed on the x-axis: the ‘Fold change’s and the ‘Difference’s. You control which to plot in the side panel. If you have filtered on ‘Fold change’ you will typically want to choose ‘Fold change’ in the side panel. If you have filtered on ‘Difference’ (e.g. because your original data is on the log scale, see the note on fold change in 29.2.2) you typically want to choose ‘Difference’.

29.3 Transformation and normalization

The original expression values often need to be transformed and/or normalized in order to ensure that samples are comparable and assumptions on the data for analysis are met [Allison et al., 2006]. These are essential requirements for carrying out a meaningful analysis. The raw expression values often exhibit a strong dependency of the variance on the mean, and it may be preferable to remove this by log-transforming the data. Furthermore, the sets of expression values in the different samples in an experiment may exhibit systematic differences that are likely due to differences in sample preparation and array processing, rather being the result of the underlying biology. These noise effects should be removed before statistical analysis is carried out.

When you perform transformation and normalization, the original expression values will be kept, and the new values will be added. If you select an experiment ( ), the new values will be added to the experiment (not the original samples). And likewise if you select a sample ( ) - in this case the new values will be added to the sample (the original values are still kept on the sample).
29.3.1 Selecting transformed and normalized values for analysis

A number of the tools for Expression Analysis use the following expression level values: Original, Transformed and Normalized (figure 29.37).

![Figure 29.37: Selecting which version of the expression values to analyze. In this case, the values have not been normalized, so it is not possible to select normalized values.](image)

In this case, the values have not been normalized, so it is not possible to select normalized values.

29.3.2 Transformation

The CLC Genomics Workbench lets you transform expression values based on logarithm and adding a constant:

Toolbox | Microarray and Small RNA Analysis ( ) | Transformation and Normalization | Transform ( )

Select a number of samples ( ) or ( ) or an experiment ( ) and click Next.

This will display a dialog as shown in figure 29.38.

![Figure 29.38: Transforming expression values.](image)

At the top, you can select which values to transform (see section 29.3.1).

Next, you can choose three kinds of transformation:
• **Logarithm transformation.** Transformed expression values will be calculated by taking the logarithm (of the specified type) of the values you have chosen to transform.
  
  - 10.
  - 2.
  - Natural logarithm.

• **Adding a constant.** Transformed expression values will be calculated by adding the specified constant to the values you have chosen to transform.

• **Square root transformation.**

Click **Finish** to start the tool.

### 29.3.3 Normalization

The *CLC Genomics Workbench* lets you normalize expression values.

To start the normalization:

1. Toolbox | Microarray and Small RNA Analysis | Transformation and Normalization | Normalize

Select a number of samples or an experiment and click **Next**.

This will display a dialog as shown in figure 29.39.

![Figure 29.39: Choosing normalization method.](image)

At the top, you can choose three kinds of normalization (for mathematical descriptions see [Bolstad et al., 2003]):

- **Scaling.** The sets of the expression values for the samples will be multiplied by a constant so that the sets of normalized values for the samples have the same ‘target’ value (see description of the **Normalization value** below).
• **Quantile.** The empirical distributions of the sets of expression values for the samples are used to calculate a common target distribution, which is used to calculate normalized sets of expression values for the samples.

• **By totals.** This option is intended to be used with count-based data, i.e. data from small RNA or expression profiling by tags. A sum is calculated for the expression values in a sample. The transformed value are generated by dividing the input values by the sample sum and multiplying by the factor (e.g. per ‘1,000,000’).

Figures 29.40 and 29.41 show the effect on the distribution of expression values when using scaling or quantile normalization, respectively.

![Box plot after scaling normalization.](image1)

**Figure 29.40: Box plot after scaling normalization.**

![Box plot after quantile normalization.](image2)

**Figure 29.41: Box plot after quantile normalization.**

At the bottom of the dialog in figure 29.39, you can select which values to normalize (see section 29.3.1).

Clicking **Next** will display a dialog as shown in figure 29.42.

The following parameters can be set:

• **Normalization value.** The type of value of the samples which you want to ensure are equal for the normalized expression values
  - **Mean.**
  - **Median.**

• **Reference.** The specific value that you want the normalized value to be after normalization.
  - **Median mean.**
  - **Median median.**
– **Use another sample.**

- **Trimming percentage.** Expression values that lie below the value of this percentile, or above 100 minus the value of this percentile, in the empirical distribution of the expression values in a sample will be excluded when calculating the normalization and reference values.

Click **Finish** to start the tool.

### 29.4 Quality control

The *CLC Genomics Workbench* includes a number of tools for quality control. These allow visual inspection of the overall distributions, variability and similarity of the sets of expression values in samples, and may be used to spot unwanted systematic differences between samples, outlying samples and samples of poor quality, that you may want to exclude.

#### 29.4.1 Creating box plots - analyzing distributions

In most cases you expect the majority of genes to behave similarly under the conditions considered, and only a smaller proportion to behave differently. Thus, at an overall level you would expect the distributions of the sets of expression values in samples in a study to be similar. A boxplot provides a visual presentation of the distributions of expression values in samples. For each sample the distribution of it’s values is presented by a line representing a center, a box representing the middle part, and whiskers representing the tails of the distribution. Differences in the overall distributions of the samples in a study may indicate that normalization is required before the samples are comparable. An atypical distribution for a single sample (or a few samples), relative to the remaining samples in a study, could be due to imperfections in the preparation and processing of the sample, and may lead you to reconsider using the sample(s).

To create a box plot:

![Toolbox | Microarray and Small RNA Analysis (>Create Box Plot (Finish Cancel)
Select a number of samples ( ), or an experiment ( ) and click Next. This will display a dialog as shown in figure 29.43.

Here you select which values to use in the box plot (see section 29.3.1). Click Finish to start the tool.

**Viewing box plots**

An example of a box plot of a two-group experiment with 12 samples is shown in figure 29.44.

Note that the boxes per default are colored according to their group relationship. At the bottom you find the names of the samples, and the y-axis shows the expression values (note that sample names are not shown in figure 29.44).

Per default the box includes the IQR values (from the lower to the upper quartile), the median is displayed as a line in the box, and the whiskers extend 1.5 times the height of the box.

In the Side Panel to the left, there is a number of options to adjust this view. Under Graph preferences, you can adjust the general properties of the box plot (see figure 29.45).

- **Lock axes** This will always show the axes even though the plot is zoomed to a detailed
level.

- **Frame** Shows a frame around the graph.

- **Show legends** Shows the data legends.

- **Tick type** Determine whether tick lines should be shown outside or inside the frame.
  - Outside
  - Inside

- **Tick lines at** Choosing Major ticks will show a grid behind the graph.
  - None
  - Major ticks

- **Vertical axis range** Sets the range of the vertical axis (y axis). Enter a value in **Min** and **Max**, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.

- **Draw median line**. This is the default - the median is drawn as a line in the box.

- **Draw mean line**. Alternatively, you can also display the mean value as a line.

- **Show outliers**. The values outside the whiskers range are called outliers. Per default they are not shown. Note that the dot type that can be set below only takes effect when outliers are shown. When you select and deselect the **Show outliers**, the vertical axis range is automatically re-calculated to accommodate the new values.

Below the general preferences, you find the **Lines and dots** preferences, where you can adjust coloring and appearance (see figure 29.46).

- **Select sample or group**. When you wish to adjust the properties below, first select an item in this drop-down menu. That will apply the changes below to this item. If your plot is based on an experiment, the drop-down menu includes both group names and sample names, as
• **Dot type**
  - None
  - Cross
  - Plus
  - Square
  - Diamond
  - Circle
  - Triangle
  - Reverse triangle
  - Dot

• **Dot color.** Allows you to choose between many different colors. Click the color box to select a color.

Note that if you wish to use the same settings next time you open a box plot, you need to save the settings of the **Side Panel** (see section 4.6).

**Interpreting the box plot**

This section will show how to interpret a box plot through a few examples.

First, if you look at figure **29.47**, you can see a box plot for an experiment with 5 groups and 27 samples.

None of the samples stand out as having distributions that are atypical: the boxes and whiskers ranges are about equally sized. The locations of the distributions however, differ some, and indicate that normalization may be required. Figure **29.48** shows a box plot for the same experiment after quantile normalization: the distributions have been brought into par.

In figure **29.49** a box plot for a two group experiment with 5 samples in each group is shown.

The distribution of values in the second sample from the left is quite different from those of other samples, and could indicate that the sample should not be used.
Chapter 29. Microarray and Small RNA Analysis

29.4.2 Hierarchical clustering of samples

A hierarchical clustering of samples is a tree representation of their relative similarity.

The tree structure is generated by

1. letting each sample be a cluster
2. calculating pairwise distances between all clusters
3. joining the two closest clusters into one new cluster

Figure 29.47: Box plot for an experiment with 5 groups and 27 samples.

Figure 29.48: Box plot after quantile normalization.

Figure 29.49: Box plot for a two-group experiment with 5 samples.
4. iterating 2-3 until there is only one cluster left (which will contain all samples).

The tree is drawn so that the distances between clusters are reflected by the lengths of the branches in the tree. Thus, features with expression profiles that closely resemble each other have short distances between them, those that are more different, are placed further apart.

(See [Eisen et al., 1998] for a classical example of application of a hierarchical clustering algorithm in microarray analysis. The example is on features rather than samples).

To start the clustering:

Toolbox | Microarray and Small RNA Analysis ( ) | Quality Control | Hierarchical Clustering of Samples ( )

Select a number of samples ( ) or ( ) or an experiment ( ) and click Next.

This will display a dialog as shown in figure 29.50. The hierarchical clustering algorithm requires that you specify a distance measure and a cluster linkage. The similarity measure is used to specify how distances between two samples should be calculated. The cluster distance metric specifies how you want the distance between two clusters, each consisting of a number of samples, to be calculated.

Figure 29.50: Parameters for hierarchical clustering of samples.

At the top, you can choose three kinds of Distance measures:

- **Euclidean distance.** The ordinary distance between two points - the length of the segment connecting them. If \( u = (u_1, u_2, \ldots, u_n) \) and \( v = (v_1, v_2, \ldots, v_n) \), then the Euclidean distance between \( u \) and \( v \) is

  \[
  |u - v| = \sqrt{\sum_{i=1}^{n} (u_i - v_i)^2}.
  \]

- **1 - Pearson correlation.** The Pearson correlation coefficient between two elements \( x = (x_1, x_2, \ldots, x_n) \) and \( y = (y_1, y_2, \ldots, y_n) \) is defined as

  \[
  r = \frac{1}{n - 1} \sum_{i=1}^{n} \left( \frac{x_i - \bar{x}}{s_x} \right) \cdot \left( \frac{y_i - \bar{y}}{s_y} \right)
  \]
where \( \bar{x}/\bar{y} \) is the average of values in \( x/y \) and \( s_x/s_y \) is the sample standard deviation of these values. It takes a value \( \in [-1, 1] \). Highly correlated elements have a high absolute value of the Pearson correlation, and elements whose values are un-informative about each other have Pearson correlation 0. Using \( 1 - |\text{Pearson correlation}| \) as distance measure means that elements that are highly correlated will have a short distance between them, and elements that have low correlation will be more distant from each other.

- **Manhattan distance.** The Manhattan distance between two points is the distance measured along axes at right angles. If \( u = (u_1, u_2, \ldots, u_n) \) and \( v = (v_1, v_2, \ldots, v_n) \), then the Manhattan distance between \( u \) and \( v \) is

\[
|u - v| = \sum_{i=1}^{n} |u_i - v_i|.
\]

Next, you can select the cluster linkage to be used:

- **Single linkage.** The distance between two clusters is computed as the distance between the two closest elements in the two clusters.

- **Average linkage.** The distance between two clusters is computed as the average distance between objects from the first cluster and objects from the second cluster. The averaging is performed over all pairs \((x, y)\), where \( x \) is an object from the first cluster and \( y \) is an object from the second cluster.

- **Complete linkage.** The distance between two clusters is computed as the maximal object-to-object distance \( d(x_i, y_j) \), where \( x_i \) comes from the first cluster, and \( y_j \) comes from the second cluster. In other words, the distance between two clusters is computed as the distance between the two farthest objects in the two clusters.

At the bottom, you can select which values to cluster (see section 29.3.1).

Click **Finish** to start the tool.

**Note:** To be run on a server, the tool has to be included in a workflow, and the results will be displayed in a a stand-alone new heat map rather than added into the input experiment table.

**Result of hierarchical clustering of samples**

The result of a sample clustering is shown in figure 29.51.

If you have used an experiment ( ) and ran the non-workflow version of the tool, the clustering is added to the experiment and will be saved when you save the experiment. It can be viewed by clicking the Show Heat Map ( ) button at the bottom of the view (see figure 29.52).

If you have run the workflow version of the tool, or selected a number of samples ( ) as input, a new element will be created that has to be saved separately.

Regardless of the input, the view of the clustering is the same. As you can see in figure 29.51, there is a tree at the bottom of the view to visualize the clustering. The names of the samples are listed at the top. The features are represented as horizontal lines, colored according to the expression level. If you place the mouse on one of the lines, you will see the names of the
feature to the left. The features are sorted by their expression level in the first sample (in order to cluster the features, see section 29.6.1).

Researchers often have a priori knowledge of which samples in a study should be similar (e.g., samples from the same experimental condition) and which should be different (samples from biological distinct conditions). Thus, researchers have expectations about how they should cluster. Samples that are placed unexpectedly in the hierarchical clustering tree may be samples that have been wrongly allocated to a group, samples of unintended or unclean tissue composition or samples for which the processing has gone wrong. Unexpectedly placed samples, of course, could also be highly interesting samples.

There are a number of options to change the appearance of the heat map. At the top of the Side Panel, you find the Heat map preference group (see figure 29.53).

At the top, there is information about the heat map currently displayed. The information regards
type of clustering, expression value used together with distance and linkage information. If you have performed more than one clustering, you can choose between the resulting heat maps in a drop-down box (see figure 29.66).

Figure 29.54: When more than one clustering has been performed, there will be a list of heat maps to choose from.

Note that if you perform an identical clustering, the existing heat map will simply be replaced. Below this box, there is a number of settings for displaying the heat map.

- **Lock width to window.** When you zoom in the heat map, you will per default only zoom in on the vertical level. This is because the width of the heat map is locked to the window. If you uncheck this option, you will zoom both vertically and horizontally. Since you always have more features than samples, it is useful to lock the width since you then have all the samples in view all the time.

- **Lock height to window.** This is the corresponding option for the height. Note that if you check both options, you will not be able to zoom at all, since both the width and the height is fixed.

- **Lock headers and footers.** This will ensure that you are always able to see the sample and feature names and the trees when you zoom in.

- **Colors.** The expression levels are visualized using a gradient color scheme, where the right side color is used for high expression levels and the left side color is used for low expression levels. You can change the coloring by clicking the box, and you can change the relative coloring of the values by dragging the two knobs on the white slider above.

Below you find the **Samples** and **Features** groups. They contain options to show names, legend, and tree above or below the heatmap. Note that for clustering of samples, you find the tree options in the **Samples** group, and for clustering of features, you find the tree options in the **Features** group. With the tree options, you can also control the **Tree size**, from tiny to very large, and the option of showing the full tree, no matter how much space it will use.

Note that if you wish to use the same settings next time you open a heat map, you need to save the settings of the **Side Panel** (see section 4.6).
29.4.3 Principal component analysis

A principal component analysis is a mathematical analysis that identifies and quantifies the directions of variability in the data. For a set of samples, e.g. an experiment, this can be done either by finding the eigenvectors and eigenvalues of the covariance matrix of the samples or the correlation matrix of the samples (the correlation matrix is a ‘normalized’ version of the covariance matrix: the entries in the covariance matrix look like this $\text{Cov}(X, Y)$, and those in the correlation matrix like this: $\text{Cov}(X, Y)/(sd(X) \times sd(Y))$. A covariance may be any value, but a correlation is always between -1 and 1).

The eigenvectors are orthogonal. The first principal component is the eigenvector with the largest eigenvalue, and specifies the direction with the largest variability in the data. The second principal component is the eigenvector with the second largest eigenvalue, and specifies the direction with the second largest variability. Similarly for the third, etc. The data can be projected onto the space spanned by the eigenvectors. A plot of the data in the space spanned by the first and second principal component will show a simplified version of the data with variability in other directions than the two major directions of variability ignored.

To start the analysis:

Select a number of samples or an experiment and click Next. This will display a dialog as shown in figure 29.55.

Figure 29.55: Selecting which values the principal component analysis should be based on.

In this dialog, you select the values to be used for the principal component analysis (see section 29.3.1).

Click Finish to start the tool.

Principal component analysis plot

This will create a principal component plot as shown in figure 29.56.

The plot shows the projection of the samples onto the two-dimensional space spanned by the first and second principal component of the covariance matrix. In the bottom part of the side-panel, the ‘Projection/Correlation’ part, you can change to show the projection onto the correlation matrix rather than the covariance matrix by choosing ‘Correlation scatter plot’. Both plots will show how the samples separate along the two directions between which the samples exhibit the largest amount of variation. For the ‘projection scatter plot’ this variation is measured in absolute
terms, and depends on the units in which you have measured your samples. The correlation scatter plot is a normalized version of the projection scatter plot, which makes it possible to compare principal component analysis between experiments, even when these have not been done using the same units (e.g. an experiment that uses 'original' scale data and another one that uses 'log-scale' data).

The plot in figure 29.56 is based on a two-group experiment. The group relationships are indicated by color. We expect the samples from within a group to exhibit less variability when compared, than samples from different groups. Thus samples should cluster according to groups and this is what we see. The PCA plot is thus helpful in identifying outlying samples and samples that have been wrongly assigned to a group.

In the Side Panel to the left, there is a number of options to adjust the view. Under Graph preferences, you can adjust the general properties of the plot.

- **Lock axes** This will always show the axes even though the plot is zoomed to a detailed level.
- **Frame** Shows a frame around the graph.
- **Show legends** Shows the data legends.
- **Tick type** Determine whether tick lines should be shown outside or inside the frame.
  - Outside
  - Inside
- **Tick lines at** Choosing Major ticks will show a grid behind the graph.
  - None
  - Major ticks
• **Horizontal axis range** Sets the range of the horizontal axis (x axis). Enter a value in **Min** and **Max**, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.

• **Vertical axis range** Sets the range of the vertical axis (y axis). Enter a value in **Min** and **Max**, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.

• **y = 0 axis.** Draws a line where y = 0. Below there are some options to control the appearance of the line:
  
  – **Line width**
    * Thin
    * Medium
    * Wide
  
  – **Line type**
    * None
    * Line
    * Long dash
    * Short dash
  
  – **Line color.** Allows you to choose between many different colors. Click the color box to select a color.

Below the general preferences, you find the **Dot properties**:

• **Drop down menu** In this you choose which of the samples (that is, which 'dots') the choices you make below should apply to. You can choose between 'All', a particular group in your experiment, or a particular samples in your experiment.

• **Select sample or group.** When you wish to adjust the properties below, first select an item in this drop-down menu. That will apply the changes below to this item. If your plot is based on an experiment, the drop-down menu includes both group names and sample names, as well as an entry for selecting "All". If your plot is based on single elements, only sample names will be visible. Note that there are sometimes "mixed states" when you select a group where two of the samples e.g. have different colors. Selecting a new color in this case will erase the differences.

• **Dot type**
  
  – None
  – Cross
  – Plus
  – Square
  – Diamond
  – Circle
  – Triangle
  – Reverse triangle
Dot

- **Dot color.** Allows you to choose between many different colors. Click the color box to select a color.

- **Show name.** This will show a label with the name of the sample next to the dot. Note that the labels quickly get crowded, so that is why the names are not put on per default.

Note that if you wish to use the same settings next time you open a principal component plot, you need to save the settings of the **Side Panel** (see section 4.6).

**Scree plot**

Besides the view shown in figure 29.56, the result of the principal component can also be viewed as a scree plot by clicking the **Show Scree Plot** button at the bottom of the view. The scree plot shows the proportion of variation in the data explained by each of the principal components. The first principal component accounts for the largest part of the variability.

In the **Side Panel** to the left, there is a number of options to adjust the view. Under **Graph preferences**, you can adjust the general properties of the plot.

- **Lock axes** This will always show the axes even though the plot is zoomed to a detailed level.

- **Frame** Shows a frame around the graph.

- **Show legends** Shows the data legends.

- **Tick type** Determine whether tick lines should be shown outside or inside the frame.
  - Outside
  - Inside

- **Tick lines at** Choosing Major ticks will show a grid behind the graph.
  - None
  - Major ticks

- **Horizontal axis range** Sets the range of the horizontal axis (x axis). Enter a value in **Min** and **Max**, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.

- **Vertical axis range** Sets the range of the vertical axis (y axis). Enter a value in **Min** and **Max**, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.

The **Lines and plots** below contains the following parameters:

- **Dot type**
  - None
  - Cross
- Plus
- Square
- Diamond
- Circle
- Triangle
- Reverse triangle
- Dot

- **Dot color.** Allows you to choose between many different colors. Click the color box to select a color.

- **Line width**
  - Thin
  - Medium
  - Wide

- **Line type**
  - None
  - Line
  - Long dash
  - Short dash

- **Line color.** Allows you to choose between many different colors. Click the color box to select a color.

Note that the graph title and the axes titles can be edited simply by clicking them with the mouse. These changes will be saved when you **Save** the graph - whereas the changes in the **Side Panel** need to be saved explicitly (see section 4.6).

### 29.5 Statistical analysis - identifying differential expression

The *CLC Genomics Workbench* is designed to help you identify differential expression.

You have a choice of a number of standard statistical tests, that are suitable for different data types and different types of experimental settings. There are two main types of tests: tests that assume that data consists of counts and compare these or their proportions (described in section 29.5.1 and section 29.5.2) and tests that assume that the data is real-valued, has Gaussian distributions and compare means (described in section 29.5.3).

To run the statistical analysis:

- Microarray and Small RNA Analysis ( yanlış) Statistical Analysis  |  Empirical Analysis of DGE ( yanlış)
- Microarray and Small RNA Analysis ( yanlış) Statistical Analysis  |  Proportion-based Statistical Analysis ( yanlış)
or Microarray and Small RNA Analysis (Statistics) | Statistical Analysis | Gaussian Statistical Analysis

For all kinds of statistical analyses, you first select the experiment that you wish to use and click Next (learn more about setting up experiments in section 29.2.1).

The first part of the explanation of how to proceed and perform the statistical analysis is divided into three, depending on whether you are doing Empirical analysis of DGE, tests on proportions or Gaussian-based tests. The last part has an explanation of the options regarding corrected p-values which applies to all tests.

29.5.1 Empirical analysis of DGE

The Empirical analysis of DGE tool implements the 'Exact Test' for two-group comparisons developed by Robinson and Smyth [Robinson and Smyth, 2008] and incorporated in the edgeR Bioconductor package [Robinson et al., 2010]. The test is applicable to count data only, and is designed specifically to deal with situations in which many features are studied simultaneously (e.g. genes in a genome) but where only a few biological replicates are available for each of the experimental groups studied.

The test uses the raw counts, and implicitly carries out normalization and transformation of these counts (see below for details). It is based on the assumption that the count data follows a Negative Binomial distribution, which in contrast to the Poisson distribution has the characteristic that it allows for a non-constant mean-variance relationship. The test is also appropriate for larger numbers of samples.

The 'Exact Test' of Robinson and Smyth is similar to Fisher’s Exact Test, but also accounts for overdispersion caused by biological variability. Whereas Fisher’s Exact Test compares the counts in one sample against those of another, the 'Exact Test' compares the counts in one set of count samples against those in another set of count samples. This is achieved by replacing the Hypergeometric distributions of Fisher’s Exact Test by Negative binomial distributions, whereby the variability within each of the two groups of samples compared is taken into account. This only works if the dispersions in the two groups compared are identical. As this cannot generally be assumed to be the case for the original (nor for the normalized) data, pseudodata for which the dispersion is identical is generated from the original data, and the test is carried out on this pseudodata. The generation of the pseudodata is performed simultaneously with the estimation of the dispersion, in an iterative procedure called quantile-adjusted conditional maximum likelihood. Either a single common dispersion for all features may be assumed (as in [Robinson and Smyth, 2008]), or it may be assumed that the dispersion for each feature (e.g. gene) is a ‘weighted average’ of the common dispersion and feature (e.g. gene) specific dispersions (as suggested in [Robinson and Smyth, 2007]). The weight given to each of the components depends on the number of samples in the groups: the more samples there are in the groups, the higher the weight will be given to the gene-specific component.

The Exact Test in the edgeR Bioconductor package provides the user with the option to set a large number of parameters. The implementation of the ‘Empirical analysis of DGE’ algorithm in the Genomics Workbench uses for the most parts the default settings in the edgeR package, version 3.4.0. A detailed outline of the parameter settings is given in section 29.5.1).
Empirical analysis of DGE - implementation parameters

The 'Empirical analysis of DGE' algorithm in the CLC Genomics Workbench is a re-implementation of the "Exact Test", available as part of the edgeR Bioconductor package.

The parameter values used in the CLC Genomics Workbench implementation are the default values for the equivalent parameters in the edgeR Bioconductor implementation in all but one case. The exception is the estimateCommonDisp tol parameter, where the default is more stringent than that of edgeR. The advantage of using a more stringent value for this parameter is that the results will be more accurate. The disadvantage is that the algorithm will be slightly slower, however according to our performance tests, this change has only a marginal impact on the run time of the tool.

The parameter values used in the CLC Genomics Workbench implementation, with reference to the edgeR function names for clarity, are provided in the table below.

Running the Empirical analysis of DGE

First, find the Empirical analysis of DGE tool:

Toolbox | Microarray and Small RNA Analysis (/chart)| Statistical Analysis | Empirical Analysis of DGE (chart)

The original count data for a full expression experiment are the expected input to the Empirical Analysis of DGE tool.
When Experiments created within the Workbench are used as input, the original count values are always used. Columns of such Experiments that contain transformed or normalized values are ignored.

If expression values are being imported from outside the Workbench for use with this test, the data should be original (non-transformed, non-normalized) counts.

Whether the data has been generated in the Workbench or outside the Workbench and imported, the full set of expression results should be used. Please do not run this test on a subset of values from the original sample data.

The reason that the complete set of original count data for samples should be used as input to this test is that the algorithm assumes that the counts on which it operates are Negative Binomially distributed. It implicitly normalizes and transforms these counts, so if the counts have been altered prior to submitting them to the Empirical Analysis of DGE tool, this assumption is likely to be compromised.

When running the Empirical analysis of DGE tool in the Genomics workbench, the user is asked to specify two parameters related to the estimation of the dispersion (figure 29.57). Of these, the ‘Total count filter cut-off’ specifies which features should be considered when estimating the common dispersion component. Features for which the counts across all samples are low are likely to contribute mostly with noise to the estimation, and features with a lower cumulative count across samples than the value specified will be ignored. When the check-box ‘Estimate tag-wise dispersions’ is checked, the dispersion estimate for each gene will be a weighted combination of the tag-wise and common dispersion, if the check-box is un-ticked the common dispersion will be used for all genes.

The Empirical analysis of DGE may be carried out between all pairs of groups (by clicking the ‘All pairs’ button) or for each group against a specified reference group (by clicking the ‘Against reference’ button) (figure 29.58). In the last case you must specify which of the groups you want to use as reference (the default is to use the group you specified as Group 1 when you set up the experiment). For example, the All pairs option should be selected when you wish to perform the test of equality for group means for all of the pairs, e.g. if you would like to compare different tissues where each tissue is represented in a group. In this case there is no reference group, so the following comparisons will be performed:

- liver vs heart
- liver vs lung
- heart vs lung

Figure 29.57: Empirical analysis of DGE: setting the parameters related to dispersion.
The Against reference option should be selected when you wish to perform the test of equality for group means against one group, the reference, rather than all groups as above. Against reference could be used if you have a wild type and some mutant groups, e.g. Wild type, Mutant 1 and Mutant 2. In this case you might be interested in comparing the mutants to the wild type, but comparing the mutants to each other is not of interest. In this case the Wild Type group is considered the reference and the comparisons will be performed:

- Wild type vs Mutant 1
- Wild type vs Mutant 2

Note that with the Against reference option fewer comparisons are made, as in the above example where Mutant 1 vs. Mutant 2 is not considered.

Below you can select to add two kinds of corrected p-values to the analysis (in addition to the standard p-value produced for the test statistic):

- **Bonferroni corrected.**
- **FDR corrected.**

Both are calculated from the original p-values, and aim in different ways to take into account the issue of multiple testing [Dudoit et al., 2003]. The problem of multiple testing arises because the original p-values are related to a single test: the p-value is the probability of observing a more extreme value than that observed in the test carried out. If the p-value is 0.04, we would expect an as extreme value as that observed in 4 out of 100 tests carried out among groups with no difference in means. Popularly speaking, if we carry out 10000 tests and select the features with original p-values below 0.05, we will expect about 0.05 times 10000 = 500 to be false positives.

The Bonferroni corrected p-values handle the multiple testing problem by controlling the ‘family-wise error rate’: the probability of making at least one false positive call. They are calculated by multiplying the original p-values by the number of tests performed. The probability of having at least one false positive among the set of features with Bonferroni corrected p-values below 0.05, is less than 5%. The Bonferroni correction is conservative: there may be many genes that are differentially expressed among the genes with Bonferroni corrected p-values above 0.05, that will be missed if this correction is applied.

Instead of controlling the family-wise error rate we can control the false discovery rate: FDR. The false discovery rate is the proportion of false positives among all those declared positive. We expect 5 % of the features with FDR corrected p-values below 0.05 to be false positive. There are many methods for controlling the FDR - the method used in CLC Genomics Workbench is that of [Benjamini and Hochberg, 1995].

When the Empirical analysis of DGE is run three columns will be added to the experiment table for each pair of groups that are analyzed: the ‘P-value’, ‘Fold change’ and ‘Weighted difference’ columns. The ‘P-value’ holds the p-value for the Exact test. The ‘Fold Change’ and ‘Weighted difference’ columns are both calculated from the estimated relative abundances, which are derived internally in the Exact Test algorithm. They depend on both the sizes (depth of coverage/library size) of the samples, the magnitude of the counts and on the estimated negative binomial dispersion, so they cannot be obtained from the original counts by simple algebraic calculations.
The 'Fold Change' will tell you how many times bigger the relative abundance of group 2 is relative to that of group 1. If the relative abundance of group 2 is bigger than that of group 1 the fold change is the relative abundance of group 2 divided by that of group 1. If the relative abundance of group 2 is smaller than that of group 1 the fold change is the relative abundance of group 1 divided by that of group 2 with a negative sign. The 'weighted difference' column contains the difference between the relative abundance of group 2 and the relative abundance of group 1. In addition to the three automatically added columns, columns containing the Bonferroni and FDR corrected p-values will be added if that was specified by the user.

### 29.5.2 Tests on proportions

The proportions-based tests are applicable in situations where your data samples consists of counts of a number of 'types' of data. This could e.g. be in a study where gene expression levels are measured by tag profiling for example. Here the different 'types' could correspond to the different 'genes' in a reference genome, and the counts could be the numbers of reads matching each of these genes. The tests compare counts by considering the proportions that they make up the total sum of counts in each sample. By comparing the expression levels at the level of proportions rather than raw counts, the data is corrected for sample size.

There are two tests available for comparing proportions: the test of [Kal et al., 1999] and the test of [Baggerly et al., 2003]. Both tests compare pairs of groups. If you have a multi-group experiment (see section 29.2.1), you may choose either to have tests produced for all pairs of groups (by clicking the 'All pairs' button) or to have a test produced for each group compared to a specified reference group (by clicking the 'Against reference' button). In the last case you must specify which of the groups you want to use as reference (the default is to use the group you specified as Group 1 when you set up the experiment).

Note that the proportion-based tests use the total sample counts (that is, the sum over all expression values). If one (or more) of the counts are NaN, the sum will be NaN and all the test statistics will be NaN. As a consequence all p-values will also be NaN. You can avoid this by filtering your experiment and creating a new experiment so that no NaN values are present, before you apply the tests.
Kal et al.’s test (Z-test)

Kal et al.’s test [Kal et al., 1999] compares a single sample against another single sample, and thus requires that each group in your experiment has only one sample. The test relies on an approximation of the binomial distribution by the normal distribution [Kal et al., 1999]. Considering proportions rather than raw counts the test is also suitable in situations where the sum of counts is different between the samples.

When Kal’s test is run on an experiment four columns will be added to the experiment table for each pair of groups that are analyzed. The 'Proportions difference' column contains the difference between the proportion in group 2 and the proportion in group 1. The 'Fold Change' column tells you how many times bigger the proportion in group 2 is relative to that of group 1. If the proportion in group 2 is bigger than that in group 1 this value is the proportion in group 2 divided by that in group 1. If the proportion in group 2 is smaller than that in group 1 the fold change is the proportion in group 1 divided by that in group 2 with a negative sign. The 'Test statistic' column holds that value of the test statistic, and the 'P-value' holds the two-sided p-value for the test. Up to two more columns may be added if the options to calculate Bonferroni and FDR corrected p-values were chosen.

Baggerley et al.’s test (Beta-binomial)

Baggerley et al.’s test [Baggerly et al., 2003] compares the proportions of counts in a group of samples against those of another group of samples, and is suited to cases where replicates are available in the groups. The samples are given different weights depending on their sizes (total counts). The weights are obtained by assuming a Beta distribution on the proportions in a group, and estimating these, along with the proportion of a binomial distribution, by the method of moments. The result is a weighted t-type test statistic.

When Baggerley’s test is run on an experiment four columns will be added to the experiment table for each pair of groups that are analyzed. The 'Weighted proportions difference' column contains the difference between the mean of the weighted proportions across the samples assigned to group 2 and the mean of the weighted proportions across the samples assigned to group 1. The 'Weighted proportions fold change' column tells you how many times bigger the mean of the weighted proportions in group 2 is relative to that of group 1. If the mean of the weighted proportions in group 2 is bigger than that in group 1 this value is the mean of the weighted proportions in group 2 divided by that in group 1. If the mean of the weighted proportions in group 2 is smaller than that in group 1 the fold change is the mean of the weighted proportions in group 1 divided by that in group 2 with a negative sign. The ‘Test statistic’ column holds that value of the test statistic, and the ‘P-value’ holds the two-sided p-value for the test. Up to two more columns may be added if the options to calculate Bonferroni and FDR corrected p-values were chosen.

29.5.3 Gaussian-based tests

The tests based on the Gaussian distribution essentially compare the mean expression level in the experimental groups in the study, and evaluates the significance of the difference relative to the variance (or ‘spread’) of the data within the groups. The details of the formula used for calculating the test statistics vary according to the experimental setup and the assumptions you make about the data (read more about this in the sections on t-test and ANOVA below). The explanation of how to proceed is divided into two, depending on how many groups there are in
your experiment. First comes the explanation for t-tests which is the only analysis available for two-group experimental setups (t-tests can also be used for pairwise comparison of groups in multi-group experiments). Next comes an explanation of the ANOVA test which can be used for multi-group experiments.

Note that the test statistics for the t-test and ANOVA analysis use the estimated group variances in their denominators. If all expression values in a group are identical the estimated variance for that group will be zero. If the estimated variances for both (or all) groups are zero the denominator of the test statistic will be zero. The numerator’s value depends on the difference of the group means. If this is zero, the numerator is zero and the test statistic will be 0/0 which is NaN. If the numerator is different from zero the test statistic will be + or - infinity, depending on which group mean is bigger. If all values in all groups are identical the test statistic is set to zero.

**T-tests**

For experiments with two groups you can, among the Gaussian tests, only choose a T-test as shown in figure 29.59.

![Figure 29.59: Selecting a t-test.](image)

There are different types of t-tests, depending on the assumption you make about the variances in the groups. By selecting ‘Homogeneous’ (the default) calculations are done assuming that the groups have equal variances. When ‘In-homogeneous’ is selected, this assumption is not made.

The t-test can also be chosen if you have a multi-group experiment. In this case you may choose either to have t-tests produced for all pairs of groups (by clicking the ‘All pairs’ button) or to have a t-test produced for each group compared to a specified reference group (by clicking the ‘Against reference’ button). In the last case you must specify which of the groups you want to use as reference (the default is to use the group you specified as Group 1 when you set up the experiment).

If a experiment with pairing was set up (see section 29.2.1) the Use pairing tick box is active. If ticked, paired t-tests will be calculated, if not, the formula for the standard t-test will be used.

When a t-test is run on an experiment four columns will be added to the experiment table for
each pair of groups that are analyzed. The 'Difference' column contains the difference between
the mean of the expression values across the samples assigned to group 2 and the mean of
the expression values across the samples assigned to group 1. The 'Fold Change' column tells
you how many times bigger the mean expression value in group 2 is relative to that of group 1.
If the mean expression value in group 2 is bigger than that in group 1 this value is the mean
expression value in group 2 divided by that in group 1. If the mean expression value in group 2
is smaller than that in group 1 the fold change is the mean expression value in group 1 divided
by that in group 2 with a negative sign. The 'Test statistic' column holds that value of the test
statistic, and the 'P-value' holds the two-sided p-value for the test. Up to two more columns may
be added if the options to calculate Bonferroni and FDR corrected p-values were chosen.

**ANOVA**

For experiments with more than two groups you can choose T-test as described above, or ANOVA.
The ANOVA method allows analysis of an experiment with one factor and a number of groups,
e.g. different types of tissues, or time points. In the analysis, the variance within groups is
compared to the variance between groups. You get a significant result (that is, a small ANOVA
p-value) if the difference you see between groups relative to that within groups, is larger than
what you would expect, if the data were really drawn from groups with equal means.

If an experiment with pairing was set up (see section 29.2.1) the Use pairing tick box is active.
If ticked, a repeated measures one-way ANOVA test will be calculated, if not, the formula for the
standard one-way ANOVA will be used.

When an ANOVA analysis is run on an experiment four columns will be added to the experiment
table for each pair of groups that are analyzed. The 'Max difference' column contains the
difference between the maximum and minimum of the mean expression values of the groups,
multiplied by -1 if the group with the maximum mean expression value occurs before the group
with the minimum mean expression value (with the ordering: group 1, group 2, ...). The 'Max fold
change' column contains the ratio of the maximum of the mean expression values of the groups
to the minimum of the mean expression values of the groups, multiplied by -1 if the group with the
maximum mean expression value occurs before the group with the minimum mean expression
value (with the ordering: group 1, group 2, ...). The 'Test statistic' column holds the value of the
test statistic, and the 'P-value' holds the two-sided p-value for the test. Up to two more columns
may be added if the options to calculate Bonferroni and FDR corrected p-values were chosen.

**29.5.4 Corrected p-values**

Clicking Next will display a dialog as shown in figure 29.60.

At the top, you can select which values to analyze (see section 29.3.1).

Below you can select to add two kinds of corrected p-values to the analysis (in addition to the
standard p-value produced for the test statistic):

- Bonferroni corrected.
- FDR corrected.

Both are calculated from the original p-values, and aim in different ways to take into account the
issue of multiple testing [Dudoit et al., 2003]. The problem of multiple testing arises because
the original p-values are related to a single test: the p-value is the probability of observing a more extreme value than that observed in the test carried out. If the p-value is 0.04, we would expect an as extreme value as that observed in 4 out of 100 tests carried out among groups with no difference in means. Popularly speaking, if we carry out 10000 tests and select the features with original p-values below 0.05, we will expect about 0.05 times 10000 = 500 to be false positives.

The Bonferroni corrected p-values handle the multiple testing problem by controlling the ‘family-wise error rate’: the probability of making at least one false positive call. They are calculated by multiplying the original p-values by the number of tests performed. The probability of having at least one false positive among the set of features with Bonferroni corrected p-values below 0.05, is less than 5%. The Bonferroni correction is conservative: there may be many genes that are differentially expressed among the genes with Bonferroni corrected p-values above 0.05, that will be missed if this correction is applied.

Instead of controlling the family-wise error rate we can control the false discovery rate: FDR. The false discovery rate is the proportion of false positives among all those declared positive. We expect 5 % of the features with FDR corrected p-values below 0.05 to be false positive. There are many methods for controlling the FDR - the method used in CLC Genomics Workbench is that of [Benjamini and Hochberg, 1995].

Click Finish to start the tool.

Note that if you have already performed statistical analysis on the same values, the existing one will be overwritten.

29.5.5 Volcano plots - inspecting the result of the statistical analysis

The results of the statistical analysis are added to the experiment and can be shown in the experiment table (see section 29.2.2). Typically columns containing the differences (or weighted differences) of the mean group values and the fold changes (or weighted fold changes) of the mean group values will be added along with a column of p-values. Also, columns with FDR or Bonferroni corrected p-values will be added if these were calculated. This added information allows features to be sorted and filtered to exclude the ones without sufficient proof of differential expression (learn more in section 3.3).

If you want a more visual approach to the results of the statistical analysis, you can click the Show Volcano Plot button at the bottom of the experiment table view. In the same way as the
scatter plot presented in section 29.2.4, the volcano plot is yet another view on the experiment. Because it uses the p-values and mean differences produced by the statistical analysis, the plot is only available once a statistical analysis has been performed on the experiment.

An example of a volcano plot is shown in figure 29.61.

![Volcano Plot](image)

**Figure 29.61: Volcano plot.**

The volcano plot shows the relationship between the p-values of a statistical test and the magnitude of the difference in expression values of the samples in the groups. On the y-axis the $-\log_{10} p$-values are plotted. For the x-axis you may choose between two sets of values by choosing either 'Fold change' or 'Difference' in the volcano plot side panel's 'Values' part. If you choose 'Fold change' the log of the values in the 'fold change' (or 'Weighted fold change') column for the test will be displayed. If you choose 'Difference' the values in the 'Difference' (or 'Weighted difference') column will be used. Which values you wish to display will depend upon the scale of your data (Read the note on fold change in section 29.2.2).

The larger the difference in expression of a feature, the more extreme it’s point will lie on the X-axis. The more significant the difference, the smaller the p-value and thus the higher the $-\log_{10}(p)$ value. Thus, points for features with highly significant differences will lie high in the plot. Features of interest are typically those which change significantly and by a certain magnitude. These are the points in the upper left and upper right hand parts of the volcano plot.

If you have performed different tests or you have an experiment with multiple groups you need to specify for which test and which group comparison you want the volcano plot to be shown. You do this in the 'Test' and 'Values' parts of the volcano plot side panel.

Options for the volcano plot are described in further detail when describing the Side Panel below.

If you place your mouse on one of the dots, a small text box will tell the name of the feature. Note that you can zoom in and out on the plot (see section 2.2).

In the Side Panel to the right, there is a number of options to adjust the view of the volcano plot.
Under Graph preferences, you can adjust the general properties of the volcano plot

- **Lock axes** This will always show the axes even though the plot is zoomed to a detailed level.
- **Frame** Shows a frame around the graph.
- **Show legends** Shows the data legends.
- **Tick type** Determine whether tick lines should be shown outside or inside the frame.
  - Outside
  - Inside
- **Tick lines at** Choosing Major ticks will show a grid behind the graph.
  - None
  - Major ticks

- **Horizontal axis range** Sets the range of the horizontal axis (x axis). Enter a value in Min and Max, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.

- **Vertical axis range** Sets the range of the vertical axis (y axis). Enter a value in Min and Max, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.

Below the general preferences, you find the Dot properties, where you can adjust coloring and appearance of the dots.

- **Dot type**
  - None
  - Cross
  - Plus
  - Square
  - Diamond
  - Circle
  - Triangle
  - Reverse triangle
  - Dot

- **Dot color.** Allows you to choose between many different colors. Click the color box to select a color.

At the very bottom, you find two groups for choosing which values to display:

- **Test.** In this group, you can select which kind of test you want the volcano plot to be shown for.
• Values. Under Values, you can select which values to plot. If you have multi-group experiments, you can select which groups to compare. You can also select whether to plot Difference or Fold change on the x-axis. Read the note on fold change in section 29.2.2.

Note that if you wish to use the same settings next time you open a box plot, you need to save the settings of the Side Panel (see section 4.6).

29.6 Feature clustering

Feature clustering is used to identify and cluster together features with similar expression patterns over samples (or experimental groups). Features that cluster together may be involved in the same biological process or be co-regulated. Also, by examining annotations of genes within a cluster, one may learn about the underlying biological processes involved in the experiment studied.

29.6.1 Hierarchical clustering of features

A hierarchical clustering of features is a tree presentation of the similarity in expression profiles of the features over a set of samples (or groups).

The tree structure is generated by

1. letting each feature be a cluster
2. calculating pairwise distances between all clusters
3. joining the two closest clusters into one new cluster
4. iterating 2-3 until there is only one cluster left (which will contain all samples).

The tree is drawn so that the distances between clusters are reflected by the lengths of the branches in the tree. Thus, features with expression profiles that closely resemble each other have short distances between them, those that are more different, are placed further apart.

To start the clustering of features:

Toolbox | Microarray and Small RNA Analysis | Feature Clustering | Hierarchical Clustering of Features

Select at least two samples or an experiment.

Note! If your data contains many features, the clustering will take very long time and could make your computer unresponsive. It is recommended to perform this analysis on a subset of the data (which also makes it easier to make sense of the clustering. Typically, you will want to filter away the features that are thought to represent only noise, e.g. those with mostly low values, or with little difference between the samples). See how to create a sub-experiment in section 29.2.2.

Clicking Next will display a dialog as shown in figure 29.62. The hierarchical clustering algorithm requires that you specify a distance measure and a cluster linkage. The distance measure is used specify how distances between two features should be calculated. The cluster linkage specifies how you want the distance between two clusters, each consisting of a number of features, to be calculated.
At the top, you can choose three kinds of **Distance measures**:

- **Euclidean distance.** The ordinary distance between two points - the length of the segment connecting them. If $u = (u_1, u_2, \ldots, u_n)$ and $v = (v_1, v_2, \ldots, v_n)$, then the Euclidean distance between $u$ and $v$ is
  \[ |u - v| = \sqrt{\sum_{i=1}^{n} (u_i - v_i)^2}. \]

- **1 - Pearson correlation.** The Pearson correlation coefficient between two elements $x = (x_1, x_2, \ldots, x_n)$ and $y = (y_1, y_2, \ldots, y_n)$ is defined as
  \[ r = \frac{1}{n-1} \sum_{i=1}^{n} \frac{x_i - \bar{x}}{s_x} \cdot \frac{y_i - \bar{y}}{s_y} \]
  where $\bar{x}/\bar{y}$ is the average of values in $x/y$ and $s_x/s_y$ is the sample standard deviation of these values. It takes a value $\in [-1, 1]$. Highly correlated elements have a high absolute value of the Pearson correlation, and elements whose values are un-informative about each other have Pearson correlation 0. Using $1 - |\text{Pearson correlation}|$ as distance measure means that elements that are highly correlated will have a short distance between them, and elements that have low correlation will be more distant from each other.

- **Manhattan distance.** The Manhattan distance between two points is the distance measured along axes at right angles. If $u = (u_1, u_2, \ldots, u_n)$ and $v = (v_1, v_2, \ldots, v_n)$, then the Manhattan distance between $u$ and $v$ is
  \[ |u - v| = \sum_{i=1}^{n} |u_i - v_i|. \]

Next, you can select different ways to calculate distances between clusters. The possible cluster linkage to use are:

- **Single linkage.** The distance between two clusters is computed as the distance between the two closest elements in the two clusters.
• **Average linkage.** The distance between two clusters is computed as the average distance between objects from the first cluster and objects from the second cluster. The averaging is performed over all pairs \((x, y)\), where \(x\) is an object from the first cluster and \(y\) is an object from the second cluster.

• **Complete linkage.** The distance between two clusters is computed as the maximal object-to-object distance \(d(x_i, y_j)\), where \(x_i\) comes from the first cluster, and \(y_j\) comes from the second cluster. In other words, the distance between two clusters is computed as the distance between the two farthest objects in the two clusters.

At the bottom, you can select which values to cluster (see section 29.3.1). Click **Finish** to start the tool.

**Result of hierarchical clustering of features**

The result of a feature clustering is shown in figure 29.63.

If you have used an experiment as input, the clustering is added to the experiment and will be saved when you save the experiment. It can be viewed by clicking the **Show Heat Map** button at the bottom of the view (see figure 29.64).

If you have selected a number of samples as input, a new element will be created that has to be saved separately.
Regardless of the input, a hierarchical tree view with associated heatmap is produced (figure 29.63). In the heatmap each row corresponds to a feature and each column to a sample. The color in the $i$'th row and $j$'th column reflects the expression level of feature $i$ in sample $j$ (the color scale can be set in the side panel). The order of the rows in the heatmap are determined by the hierarchical clustering. If you place the mouse on one of the rows, you will see the name of the corresponding feature to the left. The order of the columns (that is, samples) is determined by their input order or (if defined) experimental grouping. The names of the samples are listed at the top of the heatmap and the samples are organized into groups.

There are a number of options to change the appearance of the heat map. At the top of the Side Panel, you find the Heat map preference group (see figure 29.65).

![Figure 29.65: Side Panel of heat map.](image)

At the top, there is information about the heat map currently displayed. The information regards type of clustering, expression value used together with distance and linkage information. If you have performed more than one clustering, you can choose between the resulting heat maps in a drop-down box (see figure 29.66).

![Figure 29.66: When more than one clustering has been performed, there will be a list of heat maps to choose from.](image)
Note that if you perform an identical clustering, the existing heat map will simply be replaced. Below this box, there is a number of settings for displaying the heat map.

- **Lock width to window.** When you zoom in the heat map, you will per default only zoom in on the vertical level. This is because the width of the heat map is locked to the window. If you uncheck this option, you will zoom both vertically and horizontally. Since you always have more features than samples, it is useful to lock the width since you then have all the samples in view all the time.

- **Lock height to window.** This is the corresponding option for the height. Note that if you check both options, you will not be able to zoom at all, since both the width and the height is fixed.

- **Lock headers and footers.** This will ensure that you are always able to see the sample and feature names and the trees when you zoom in.

- **Colors.** The expression levels are visualized using a gradient color scheme, where the right side color is used for high expression levels and the left side color is used for low expression levels. You can change the coloring by clicking the box, and you can change the relative coloring of the values by dragging the two knobs on the white slider above.

Below you find the **Samples** and **Features** groups. They contain options to show names, legend, and tree above or below the heatmap. Note that for clustering of samples, you find the tree options in the **Samples** group, and for clustering of features, you find the tree options in the **Features** group. With the tree options, you can also control the **Tree size**, from tiny to very large, and the option of showing the full tree, no matter how much space it will use.

Note that if you wish to use the same settings next time you open a heat map, you need to save the settings of the **Side Panel** (see section 4.6).

### 29.6.2 K-means/medoids clustering

In a k-means or medoids clustering, features are clustered into k separate clusters. The procedures seek to find an assignment of features to clusters, for which the distances between features within the cluster is small, while distances between clusters are large.

Select at least two samples ( or ) or an experiment ().

**Note!** If your data contains many features, the clustering will take very long time and could make your computer unresponsive. It is recommended to perform this analysis on a subset of the data (which also makes it easier to make sense of the clustering). See how to create a sub-experiment in section 29.2.2.

Clicking **Next** will display a dialog as shown in figure 29.67.

The parameters are:

- **Algorithm.** You can choose between two clustering methods:
- **K-means.** K-means clustering assigns each point to the cluster whose center is nearest. The center/centroid of a cluster is defined as the average of all points in the cluster. If a data set has three dimensions and the cluster has two points \( X = (x_1, x_2, x_3) \) and \( Y = (y_1, y_2, y_3) \), then the centroid \( Z \) becomes \( Z = (z_1, z_2, z_3) \), where \( z_i = (x_i + y_i)/2 \) for \( i = 1, 2, 3 \). The algorithm attempts to minimize the intra-cluster variance defined by:

\[
V = \sum_{i=1}^{k} \sum_{x_j \in S_i} (x_j - \mu_i)^2
\]

where there are \( k \) clusters \( S_i, i = 1, 2, \ldots, k \) and \( \mu_i \) is the centroid of all points \( x_j \in S_i \). The detailed algorithm can be found in [Lloyd, 1982].

- **K-medoids.** K-medoids clustering is computed using the PAM-algorithm (PAM is short for Partitioning Around Medoids). It chooses datapoints as centers in contrast to the K-means algorithm. The PAM-algorithm is based on the search for \( k \) representatives (called medoids) among all elements of the dataset. When having found \( k \) representatives \( k \) clusters are now generated by assigning each element to its nearest medoid. The algorithm first looks for a good initial set of medoids (the BUILD phase). Then it finds a local minimum for the objective function:

\[
V = \sum_{i=1}^{k} \sum_{x_j \in S_i} (x_j - c_i)^2
\]

where there are \( k \) clusters \( S_i, i = 1, 2, \ldots, k \) and \( c_i \) is the medoid of \( S_i \). This solution implies that there is no single switch of an object with a medoid that will decrease the objective (this is called the SWAP phase). The PAM-algorithm is described in [Kaufman and Rousseeuw, 1990].

- **Number of partitions.** The maximum number of partitions to cluster features into: the final number of clusters can be smaller than that.

- **Distance metric.** The metric to compute distance between data points.
– **Euclidean distance.** The ordinary distance between two elements - the length of the segment connecting them. If \( u = (u_1, u_2, \ldots, u_n) \) and \( v = (v_1, v_2, \ldots, v_n) \), then the Euclidean distance between \( u \) and \( v \) is
\[
|u - v| = \sqrt{\sum_{i=1}^{n} (u_i - v_i)^2}.
\]

– **Manhattan distance.** The Manhattan distance between two elements is the distance measured along axes at right angles. If \( u = (u_1, u_2, \ldots, u_n) \) and \( v = (v_1, v_2, \ldots, v_n) \), then the Manhattan distance between \( u \) and \( v \) is
\[
|u - v| = \sum_{i=1}^{n} |u_i - v_i|.
\]

• **Subtract mean value.** For each gene, subtract the mean gene expression value over all input samples.

Clicking **Next** will display a dialog as shown in figure **29.68.**

![Figure 29.68: Parameters for k-means/medoids clustering.](image)

At the top, you can choose the **Level** to use. Choosing 'sample values' means that distances will be calculated using all the individual values of the samples. When 'group means' are chosen, distances are calculated using the group means.

At the bottom, you can select which values to cluster (see section **29.3.1**).

Click **Finish** to start the tool.

The k-means implementation first assigns each feature to a cluster at random. Then, at each iteration, it reassigns features to the centroid of the nearest cluster. During this reassignment, it can happen that one or more of the clusters becomes empty, explaining why the final number of clusters might be smaller than the one specified in "number of partitions". Note that the initial assignment of features to clusters is random, so results can differ when the algorithm is run again.
**Viewing the result of k-means/medoids clustering**

The result of the clustering is a number of graphs. The number depends on the number of partitions chosen (figure 29.67) - there is one graph per cluster. Using drag and drop as explained in section 2.1.6, you can arrange the views to see more than one graph at the time.

Figure 29.69 shows an example where four clusters have been arranged side-by-side.

![Figure 29.69: Four clusters created by k-means/medoids clustering.](image)

The samples used are from a time-series experiment, and you can see that the expression levels for each cluster have a distinct pattern. The two clusters at the bottom have falling and rising expression levels, respectively, and the two clusters at the top both fall at the beginning but then rise again (the one to the right starts to rise earlier than the other one).

Having inspected the graphs, you may wish to take a closer look at the features represented in each cluster. In the experiment table, the clustering has added an extra column with the name of the cluster that the feature belongs to. In this way you can filter the table to see only features from a specific cluster. This also means that you can select the feature of this cluster in a volcano or scatter plot as described in section 29.2.5.
29.7 Annotation tests

The annotation tests are tools for detecting significant patterns among features (e.g. genes) of experiments, based on their annotations. This may help in interpreting the analysis of the large numbers of features in an experiment in a biological context. Which biological context, depends on which annotation you choose to examine, and could e.g. be biological process, molecular function or pathway as specified by the Gene Ontology or KEGG. The annotation testing tools of course require that the features in the experiment you want to analyze are annotated. Learn how to annotate an experiment in section 29.2.3.

29.7.1 Hypergeometric tests on annotations

The first approach to using annotations to extract biological information is the hypergeometric annotation test. This test measures the extent to which the annotation categories of features in a smaller gene list, ‘A’, are over or under-represented relative to those of the features in larger gene list ‘B’, of which ‘A’ is a sub-list. Gene list B is often the features of the full experiment, possibly with features which are thought to represent only noise, filtered away. Gene list A is a sub-experiment of the full experiment where most features have been filtered away and only those that seem of interest are kept. Typically gene list A will consist of a list of candidate differentially expressed genes. This could be the gene list obtained after carrying out a statistical analysis on the experiment, and choosing to keep only those features with FDR corrected p-values <0.05 and a fold change larger than 2 in absolute value. The hyper geometric test procedure implemented is similar to the unconditional GOstats test of [Falcon and Gentleman, 2007].

This will show a dialog where you can select the two experiments - the larger experiment, e.g. the original experiment including the full list of features - and a sub-experiment (see how to create a sub-experiment in section 29.2.2).

Click Next. This will display the dialog shown in figure 29.70.

![Figure 29.70: Parameters for performing a hypergeometric test on annotations.](image)

At the top, you select which annotation to use for testing. You can select from all the annotations
available on the experiment, but it is of course only a few that are biologically relevant. Once you have selected an annotation, you will see the number of features carrying this annotation below.

Annotations are typically given at the gene level. Often a gene is represented by more than one feature in an experiment. If this is not taken into account it may lead to a biased result. The standard way to deal with this is to reduce the set of features considered, so that each gene is represented only once. In the next step, **Remove duplicates**, you can choose the basis on which the feature set will be reduced:

- **Using gene identifier.**
- **Keep feature with:**
  - **Highest IQR.** The feature with the highest interquartile range (IQR) is kept.
  - **Highest value.** The feature with the highest expression value is kept.

First you specify which annotation you want to use as gene identifier. Once you have selected this, you will see the number of features carrying this annotation below. Next you specify which feature you want to keep for each gene. This may be either the feature with the highest inter-quartile range or the highest value.

At the bottom, you can select which values to analyze (see section 29.3.1). Only features that have a numerical value assigned to them will be used for the analysis. That is, any feature which has a value of plus infinity, minus infinity or NaN will not be included in the feature list taken into the test. Thus, the choice of value at this step can affect the features that are taken forward into the test in two ways:

- If there are features with values of plus infinity, minus infinity or NaN, those features will not be taken forward into the test. This can be a consideration when choosing transformed values, where the mathematical manipulations involved may lead to such values.
- If you chose to remove duplicates, then the value type you choose here is the value used for checking the highest IQR or value to determine which feature is taken forward into the test.

The final number of features used for the test is reported in this history view of the test results. Click **Finish** to start the tool.

**Result of hypergeometric tests on annotations**

The result of performing hypergeometric tests on annotations using GO biological process is shown in figure 29.71.

The table shows the following information:

- **Category.** This is the identifier for the category.
- **Description.** This is the description belonging to the category. Both of these are simply extracted from the annotations.
Figure 29.71: The result of testing on GO biological process.

- **Full set.** The number of features in the original experiment (not the subset) with this category. (Note that this is after removal of duplicates).

- **In subset.** The number of features in the subset with this category. (Note that this is after removal of duplicates).

- **Expected in subset.** The number of features we would have expected to find with this annotation category in the subset, if the subset was a random draw from the full set.

- **Observed - expected.** 'In subset' - 'Expected in subset'

- **p-value.** The tail probability of the hyper geometric distribution This is the value used for sorting the table.

Categories with small p-values are over-represented on the features in the subset relative to the full set.

### 29.7.2 Gene set enrichment analysis

When carrying out a hypergeometric test on annotations you typically compare the annotations of the genes in a subset containing 'the significantly differentially expressed genes' to those of the total set of genes in the experiment. Which, and how many, genes are included in the subset is somewhat arbitrary - using a larger or smaller p-value cut-off will result in including more or less. Also, the magnitudes of differential expression of the genes is not considered.

The Gene Set Enrichment Analysis (GSEA) does NOT take a sublist of differentially expressed genes and compare it to the full list - it takes a single gene list (a single experiment). The idea behind GSEA is to consider a measure of association between the genes and phenotype of interest (e.g. test statistic for differential expression) and rank the genes according to this measure of association. A test is then carried out for each annotation category, for whether the ranks of the genes in the category are evenly spread throughout the ranked list, or tend to occur at the top or bottom of the list.

The GSEA test implemented here is that of [Tian et al., 2005]. The test implicitly calculates and uses a standard t-test statistic for two-group experiments, and ANOVA statistic for multiple group
experiments for each feature, as measures of association. For each category, the test statistics for the features in that category are summed and a category based test statistic is calculated as this sum divided by the square root of the number of features in the category. Note that if a feature has the value NaN in one of the samples, the t-test statistic for the feature will be NaN. Consequently, the combined statistic for each of the categories in which the feature is included will be NaN. Thus, it is advisable to filter out any feature that has a NaN value before applying GSEA.

The p-values for the GSEA test statistics are calculated by permutation: The original test statistics for the features are permuted and new test statistics are calculated for each category, based on the permuted feature test statistics. This is done the number of times specified by the user in the wizard. For each category, the lower and upper tail probabilities are calculated by comparing the original category test statistics to the distribution of the permutation-based test statistics for that category. The lower and higher tail probabilities are the number of these that are lower and higher, respectively, than the observed value, divided by the number of permutations.

As the p-values are based on permutations you may sometimes see results where category x’s test statistic is lower than that of category y and the categories are of equal size, but where the lower tail probability of category x is higher than that of category y. This is due to imprecision in the estimations of the tail probabilities from the permutations. The higher the number of permutations, the more stable the estimation.

You may run a GSEA on a full experiment, or on a sub-experiment where you have filtered away features that you think are un-informative and represent only noise. Typically you will remove features that are constant across samples (those for which the value in the 'Range' column is zero’ — these will have a t-test statistic of zero) and/or those for which the inter-quantile range is small. As the GSEA algorithm calculates and ranks genes on p-values from a test of differential expression, it will generally not make sense to filter the experiment on p-values produced in an analysis if differential expression, prior to running GSEA on it.

Select an experiment and click Next.

Click Next. This will display the dialog shown in figure 29.72.

Figure 29.72: Gene set enrichment analysis on GO biological process.
At the top, you select which annotation to use for testing. You can select from all the annotations available on the experiment, but it is of course only a few that are biologically relevant. Once you have selected an annotation, you will see the number of features carrying this annotation below.

In addition, you can set a filter: **Minimum size required**. Only categories with more genes (i.e. features) than the specified number will be considered. Excluding categories with small numbers of genes may lead to more robust results.

Annotations are typically given at the gene level. Often a gene is represented by more than one feature in an experiment. If this is not taken into account it may lead to a biased result. The standard way to deal with this is to reduce the set of features considered, so that each gene is represented only once. Check the **Remove duplicates** check box to reduce the feature set, and you can choose how you want this to be done:

- **Using gene identifier**.
- **Keep feature with**:
  - **Highest IQR**. The feature with the highest interquartile range (IQR) is kept.
  - **Highest value**. The feature with the highest expression value is kept.

First you specify which annotation you want to use as gene identifier. Once you have selected this, you will see the number of features carrying this annotation below. Next you specify which feature you want to keep for each gene. This may be either the feature with the highest inter-quartile range or the highest value.

Clicking **Next** will display the dialog shown in figure 29.73.

![Figure 29.73: Gene set enrichment analysis parameters.](image)

At the top, you can select which values to analyze (see section 29.3.1).

Below, you can set the **Permutations for p-value calculation**. For the GSEA test a p-value is calculated by permutation: p permuted data sets are generated, each consisting of the original features, but with the test statistics permuted. The GSEA test is run on each of the permuted data sets. The test statistic is calculated on the original data, and the resulting value is compared to the distribution of the values obtained for the permuted data sets. The permutation based p-value is the number of permutation based test statistics above (or below) the value of the test statistic for the original data, divided by the number of permuted data sets. For reliable permutation-based p-value calculation a large number of permutations is required (100 is the default).
Click **Finish** to start the tool.

### Result of gene set enrichment analysis

The result of performing gene set enrichment analysis using GO biological process is shown in figure 29.74.

**Figure 29.74: The result of gene set enrichment analysis on GO biological process.**

The table shows the following information:

- **Category.** This is the identifier for the category.
- **Description.** This is the description belonging to the category. Both of these are simply extracted from the annotations.
- **Size.** The number of features with this category. (Note that this is after removal of duplicates).
- **Test statistic.** This is the GSEA test statistic.
- **Lower tail.** This is the mass in the permutation based p-value distribution below the value of the test statistic.
- **Upper tail.** This is the mass in the permutation based p-value distribution above the value of the test statistic.

A small lower (or upper) tail p-value for an annotation category is an indication that features in this category viewed as a whole are perturbed among the groups in the experiment considered.

#### 29.8 General plots

In the **General Plots** folder, you find three general plots that may be useful at various point of your analysis work flow. The plots are explained in detail below.

#### 29.8.1 Histogram

A histogram shows a distribution of a set of values. Histograms are often used for examining and comparing distributions, e.g. of expression values of different samples, in the quality control
step of an analysis. You can create a histogram showing the distribution of expression value for a sample:

Toolbox | Microarray and Small RNA Analysis | General Plots | Create Histogram

Select a number of samples or a graph track. When you have selected more than one sample, a histogram will be created for each one. Clicking Next will display a dialog as shown in figure 29.75.

![Figure 29.75: Selecting which values the histogram should be based on.](image)

In this dialog, you select the values to be used for creating the histogram (see section 29.3.1). Click Finish to start the tool.

**Viewing histograms**

The resulting histogram is shown in a figure 29.76

![Figure 29.76: Histogram showing the distribution of transformed expression values.](image)

The histogram shows the expression value on the x axis (in the case of figure 29.76 the transformed expression values) and the counts of these values on the y axis.

In the Side Panel to the left, there is a number of options to adjust the view. Under Graph preferences, you can adjust the general properties of the plot.
• **Lock axes** This will always show the axes even though the plot is zoomed to a detailed level.

• **Frame** Shows a frame around the graph.

• **Show legends** Shows the data legends.

• **Tick type** Determine whether tick lines should be shown outside or inside the frame.
  - Outside
  - Inside

• **Tick lines at** Choosing Major ticks will show a grid behind the graph.
  - None
  - Major ticks

• **Horizontal axis range** Sets the range of the horizontal axis (x axis). Enter a value in Min and Max, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.

• **Vertical axis range** Sets the range of the vertical axis (y axis). Enter a value in Min and Max, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.

• **Break points**. Determines where the bars in the histogram should be:
  - **Sturges method**. This is the default. The number of bars is calculated from the range of values by Sturges formula [Sturges, 1926].
  - **Equi-distanced bars**. This will show bars from Start to End and with a width of Sep.
  - **Number of bars**. This will simply create a number of bars starting at the lowest value and ending at the highest value.

Below the graph preferences, you find **Line color**. Allows you to choose between many different colors. Click the color box to select a color.

Note that if you wish to use the same settings next time you open a principal component plot, you need to save the settings of the **Side Panel** (see section 4.6).

Besides the histogram view itself, the histogram can also be shown in a table, summarizing key properties of the expression values. An example is shown in figure 29.77.

The table lists the following properties:

• **Number +Inf values**

• **Number -Inf values**

• **Number NaN values**

• **Number values used**

• **Total number of values**
29.8.2 MA plot

The MA plot is a scatter rotated by 45°. For two samples of expression values it plots for each gene the difference in expression against the mean expression level. MA plots are often used for quality control, in particular, to assess whether normalization and/or transformation is required.

You can create an MA plot comparing two samples:

Toolbox | Microarray and Small RNA Analysis | General Plots | Create MA Plot

In the first two dialogs, select two samples (, or ): the first must be the case expression data, and the second the control data. Clicking Next will display a dialog as shown in figure 29.78.

In this dialog, you select the values to be used for creating the MA plot (see section 29.3.1). Click Finish to start the tool.

Viewing MA plots

The resulting plot is shown in a figure 29.79.

The X axis shows the mean expression level of a feature on the two samples and the Y axis shows the difference in expression levels for a feature on the two samples. From the plot shown in figure 29.79 it is clear that the variance increases with the mean. With an MA plot like this, you will often choose to transform the expression values (see section 29.3.2).

Figure 29.80 shows the same two samples where the MA plot has been created using log2
Figure 29.79: MA plot based on original expression values.

Figure 29.80: MA plot based on transformed expression values.

The much more symmetric and even spread indicates that the dependance of the variance on the mean is not as strong as it was before transformation.

In the Side Panel to the left, there is a number of options to adjust the view. Under Graph preferences, you can adjust the general properties of the plot.

- **Lock axes** This will always show the axes even though the plot is zoomed to a detailed level.
- **Frame** Shows a frame around the graph.
- **Show legends** Shows the data legends.
- **Tick type** Determine whether tick lines should be shown outside or inside the frame.
  - Outside
  - Inside
- **Tick lines at** Choosing Major ticks will show a grid behind the graph.
  - None
- **Major ticks**

- **Horizontal axis range** Sets the range of the horizontal axis (x axis). Enter a value in Min and Max, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.

- **Vertical axis range** Sets the range of the vertical axis (y axis). Enter a value in Min and Max, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.

- **y = 0 axis.** Draws a line where y = 0. Below there are some options to control the appearance of the line:
  - **Line width**
    - Thin
    - Medium
    - Wide
  - **Line type**
    - None
    - Line
    - Long dash
    - Short dash
  - **Line color.** Allows you to choose between many different colors. Click the color box to select a color.

- **Line width**
  - Thin
  - Medium
  - Wide

- **Line type**
  - None
  - Line
  - Long dash
  - Short dash

- **Line color.** Allows you to choose between many different colors. Click the color box to select a color.

Below the general preferences, you find the **Dot properties** preferences, where you can adjust coloring and appearance of the dots:

- **Dot type**
  - None
  - Cross
– Plus
– Square
– Diamond
– Circle
– Triangle
– Reverse triangle
– Dot

• **Dot color.** Allows you to choose between many different colors. Click the color box to select a color.

Note that if you wish to use the same settings next time you open a scatter plot, you need to save the settings of the **Side Panel** (see section 4.6).

### 29.8.3 Scatter plot

As described in section 29.2.4, an experiment can be viewed as a scatter plot. However, you can also create a "stand-alone" scatter plot of two samples:

**Toolbox | Microarray and Small RNA Analysis | General Plots | Create Scatter Plot**

In the first two dialogs, select two samples ( , , or ): the first is the sample that will be plotted on the X axis of the plot, the second the one that will define the Y axis. Clicking **Next** will display a dialog as shown in figure 29.81.

![Create Scatter Plot Dialog](image)

Figure 29.81: *Selecting which values the scatter plot should be based on.*

In this dialog, you select the values to be used for creating the scatter plot (see section 29.3.1). Click **Finish** to start the tool.

For more information about the scatter plot view and how to interpret it, please see section 29.2.4.

30.1  The CLC de novo assembly algorithm

Our de novo assembly algorithm works by using de Bruijn graphs. This is a common approach used with de novo assembly algorithms described in Zerbino and Birney, 2008, Zerbino et al., 2009, Li et al., 2010, Gnerre et al., 2011. The basic idea is to make a table of all sub-sequences of a certain length (called words) found in the reads. The words are relatively short, e.g. about 20 for small data sets and 27 for a large data set. In the following section, we use the term word size to denote the length of a word. The word size is by default determined automatically (see explanation below).

Given a word in the table, we can look up all the potential neighboring words (in all the examples here, word of length 16 are used) as shown in figure 30.1.
Typically, only one of the backward neighbors and one of the forward neighbors will be present in the table. A graph can then be made where each node is a word that is present in the table and edges connect nodes that are neighbors. This is called a de Bruijn graph.

For genomic regions without repeats or sequencing errors, we get long linear stretches of connected nodes. We may choose to reduce such stretches of nodes with only one backward and one forward neighbor into nodes representing sub-sequences longer than the initial words.

Figure 30.2 shows an example where one node has two forward neighbors:

After reduction, the three first nodes are merged, and the two sets of forward neighboring nodes are also merged as shown in figure 30.3.

So bifurcations in the graph leads to separate nodes. In this case we get a total of three nodes after the reduction. Note that neighboring nodes still have an overlap (in this case 15 nucleotides since the word size is 16).

Given this way of representing the de Bruijn graph for the reads, we can consider some different situations:

When we have a SNP or a sequencing error, we get a so-called bubble (this is explained in detail in section 30.1.5) as shown in figure 30.4.

Here, the central position may be either a C or a G. If this was a sequencing error occurring only once, it would be represented in the bubble as a path that is associated with a word that only occurs a single time’. On the other hand if this was a heterozygous SNP we would see both paths represented more or less equally in terms of the number of words that support each path. Thus, having information about how many times this particular word is seen in all the reads is very useful and this information is stored in the initial word table together with the words.
The most difficult problem for de novo assembly is repeats. Repeat regions in large genomes often get very complex: a repeat may be found thousands of times and part of one repeat may also be part of another repeat. Sometimes a repeat is longer than the read length (or the paired distance when pairs are available) and then it becomes impossible to resolve the length of the repeat. This is simply because there is no information available about how to connect the nodes before the repeat to the nodes after the repeat, and we just do not know how long the repeat is.

In the simple example, if we have a repeat sequence that is present twice in the genome, we would get a graph as shown in figure 30.5.

Figure 30.5: The central node represents the repeat region that is represented twice in the genome. The neighboring nodes represent the flanking regions of this repeat in the genome.

Note that this repeat is 57 nucleotides long (the length of the sub-sequence in the central node above plus regions into the neighboring nodes where the sequences are identical). If the repeat had been shorter than 15 nucleotides, it would not have shown up as a repeat at all since the word size is 16. This is an argument for using long words in the word table. On the other hand, the longer the word, the more words from a read are affected by a sequencing error. Also, for each increment in the word size, we get one less word from each read. This is in particular an issue for very short reads. For example, if the read length is 35, we get 16 words out of each read if the word size is 20. If the word size is 25, we get only 11 words from each read.

To strike a balance, our de novo assembler chooses a word size based on the amount of input data: the more data, the longer the word length. It is based on the following:

word size 12: 0 bp - 30000 bp
word size 13: 30001 bp - 90002 bp
word size 14: 90003 bp - 270008 bp
word size 15: 270009 bp - 810026 bp
word size 16: 810027 bp - 2430080 bp
word size 17: 2430081 bp - 7290242 bp
word size 18: 7290243 bp - 21870728 bp
word size 19: 21870729 bp - 65612186 bp
word size 20: 65612187 bp - 196836560 bp
word size 21: 196836561 bp - 590509682 bp
word size 22: 590509683 bp - 1771529048 bp
word size 23: 1771529049 bp - 5314587146 bp
word size 24: 5314587147 bp - 15943761440 bp
word size 25: 15943761441 bp - 47831284322 bp
word size 26: 47831284323 bp - 143493852968 bp
word size 27: 143493852969 bp - 430481558906 bp
word size 28: 430481558907 bp - 1291444676720 bp
word size 29: 1291444676721 bp - 3874334030162 bp
word size 30: 3874334030163 bp - 11623002090488 bp
etc.

This pattern (multiplying by 3) continues until word size of 64 which is the max. See how to adjust the word size in section 30.2.3
30.1.1 Resolve repeats using reads

Having build the de Bruijn graph using words, our de novo assembler removes repeats and errors using reads. This is done in the following order:

- Remove weak edges
- Remove dead ends
- Resolve repeats using reads without conflicts
- Resolve repeats with conflicts
- Remove weak edges
- Remove dead ends

Each phase will be explained in the following subsections.

Remove weak edges

The de Bruijn graph is expected to contain artifacts from errors in the data. The number of reads agreeing upon an error is likely to be low especially compared to the number of reads without errors for the same region. When this relative difference is large enough, it’s possible to conclude something is an error.

In the remove weak edges phase we consider each node and calculate the number $c_1$ of edges connected to the node and the number of times $k_1$ a read is passing through these edges. An average of reads going through an edge is calculated $avg_1 = k_1/c_1$ and then the process is repeated using only those edges which have more than or equal $avg_1$ reads going through it. Let $c_2$ be the number of edges which meet this requirement and $k_2$ the number of reads passing through these edges. A second average $avg_2 = k_2/c_2$ is used to calculate a limit,

$$limit = \log(avg_2) + \frac{avg_2}{40}$$

and each edge connected to the node which has less than or equal $limit$ number of reads passing through it will be removed in this phase.

Remove dead ends

Some read errors might occur more often than expected, either by chance or because they are systematic sequencing errors. These are not removed by the "Remove weak edges" phase and will cause "dead ends" to occur in the graph, which are short paths in the graph that terminate after a few nodes. Furthermore, the "Remove weak edges" sometimes only removes a part of the graph, which will also leave dead ends behind. Dead ends are identified by searching for paths in the graph where there exits an alternative path containing four times more nucleotides. All nodes in such paths are then removed in this step.
Resolve repeats without conflicts

Repeats and other shared regions between the reads lead to ambiguities in the graph. These must be resolved otherwise the region will be output as multiple contigs, one for each node in the region.

The algorithm for resolving repeats without conflicts considers a number of nodes called the window. To start with, a window only contains one node, say $R$. We also define the border nodes as the nodes outside the window connected to a node in the window. The idea is to divide the border nodes into sets such that border nodes $A$ and $C$ are in the same set if there is a read going through $A$, through nodes in the window and then through $C$. If there are strictly more than one of these sets we can resolve the repeat area, otherwise we expand the window.

In the example in figure 30.6 all border nodes $A$, $B$, $C$ and $D$ are in the same set since one can reach every border nodes using reads (shown as red lines). Therefore we expand the window and in this case add node $C$ to the window as shown in figure 30.7.

![Figure 30.6: A set of nodes.](image)

After the expansion of the window, the border nodes will be grouped into two groups being set $A$, $E$ and set $B$, $D$, $F$. Since we have strictly more than one set, the repeat is resolved by copying the nodes and edges used by the reads which created the set. In the example the resolved repeat is shown in figure 30.8.

![Figure 30.7: Expanding the window to include more nodes.](image)

![Figure 30.8: Resolving the repeat.](image)
The algorithm for resolving repeats without conflict can be described the following way:

1. A node is selected as the window
2. The border is divided into sets using reads going through the window. If we have multiple sets, the repeat is resolved.
3. If the repeat cannot be resolved, we expand the window with nodes if possible and go to step 2.

The above steps are performed for every node.

**Resolve repeats with conflicts**

In the previous section repeats were resolved without excluding any reads that goes through the window. While this lead to a simpler graph, the graph will still contain artifacts, which have to be removed. The next phase removes most of these errors and is similar to the previous phase:

1. A node is selected as the initial window
2. The border is divided into sets using reads going through the window. If we have multiple sets, the repeat is resolved.
3. If the repeat cannot be resolved, the border nodes are divided into sets using reads going through the window where reads containing errors are excluded. If we have multiple sets, the repeat is resolved.
4. The window is expanded with nodes if possible and step 2 is repeated.

The algorithm described above is similar to the algorithm used in the previous section, except step 3 where the reads with errors are excluded. This is done by calculating an average $avg_1 = m_1/c_1$ where $m_1$ is the number of reads going through the window and $c_1$ is the number of distinct pairs of border nodes having one (or more) of these reads connecting them. A second average $avg_2 = m_2/c_2$ is calculated where $m_2$ is the number of reads going through the window having at least $avg_1$ or more reads connecting their border nodes and $c_2$ the number of distinct pairs of border nodes having $avg_1$ or more reads connecting them. Then, a read between two border nodes B and C is excluded if the number of reads going through B and C is less than or equal to $limit$ given by

$limit = \frac{\log(avg_2)}{2} + \frac{avg_2}{16}$

An example where we resolve a repeat with conflicts is given in 30.9 where we have a total of 21 reads going through the window with $avg_1 = 21/3 = 7$, $avg_2 = 20/2 = 10$ and $limit = 1/2 + 10/16 = 1.125$. Therefore all reads between border nodes B and C are excluded resulting in two sets of border nodes A, C and B, D. The resolved repeat is shown in figure 30.10.

### 30.1.2 Automatic paired distance estimation

The default behavior of the de novo assembler is to use the paired distances provided by the user. If the automatic paired distance estimation is enabled, the assembler will attempt to estimate the distance between paired reads. This is done by analysing the mapping of paired
reads to the long unambiguous paths in the graph which are created in the read optimization step described above. The distance estimation algorithm creates a histogram \( H \) of the paired distances between reads in each set of paired reads (see figure 30.11). Each of these histograms are then used to estimate paired distances as described in the following.

We denote the average number of observations in the histogram \( H_{\text{avg}} = \frac{1}{|H|} \sum_{d} H(d) \) where \( H(d) \) is the number of observations (reads) with distance \( d \) and \(|H|\) is the number of bins in \( H \). The gradient of \( H \) at distance \( d \) is denoted \( H'(d) \). The following algorithm is then used to compute a distance interval for each histogram.

- Identify peaks in \( H \) as \( \max_{i \leq d \leq j} H(d) \) where \([i, j]\) is any interval in \( H \) where \( \{H(d) \geq \frac{H_{\text{avg}}}{2} | i \leq d \leq j\} \).
- For the two largest peaks found, expand the respective intervals \([i, j]\) to \([k, l]\) where \( H'(k) < 0.001 \wedge k \leq i \wedge H'(l) > -0.001 \wedge j \leq l \). I.e. we search for a point in both directions where the number of observations becomes stable. A window of size 5 is used to calculate \( H' \) in this step.
- Compute the total number of observations in each of the two expanded intervals.
- If only one peak was found, the corresponding interval \([k, l]\) is used as the distance estimate unless the peak was at a negative distance in which case no distance estimate is calculated.
- If two peaks were found and the interval \([k, l]\) for the largest peak contains less than 1% of all observations, the distance is not estimated.
- If two peaks were found and the interval \([k, l]\) for the largest peak contains <2X observations compared to the smaller peak, the distance estimate is only computed if the range of distances is positive for the largest peak and negative for the smallest peak. If this is the case the interval \([k, l]\) for the positive peak is used as a distance estimate.
• If two peaks were found and the largest peak has $\geq 2X$ observations compared to the smaller peak, the interval $[k, l]$ corresponding to the largest peak is used as the distance estimate.

![Histogram of paired distances](image)

Figure 30.11: Histogram of paired distances where $H_{avg}$ is indicated by the horizontal dashed line. There is two peaks, one is at a negative distance while the other larger peak is at a positive distance. The extended interval $[k, l]$ for each peak is indicated by the vertical dotted lines.

### 30.1.3 Optimization of the graph using paired reads

When paired reads are available, we can use the paired information to resolve large repeat regions that are not spanned by individual reads, but are spanned by read pairs. Given a set of paired reads that align to two nodes connected by a repeat region, the repeat region may be resolved for those nodes if we can find a path connecting the nodes with a length corresponding to the paired read distance. However, such a path must be supported by a minimum of four sets of paired reads before the repeat is resolved.

If it’s not possible to resolve the repeat, scaffolding is performed where paired read information is used to determine the distances between contigs and the orientation of these. Scaffolding is only considered between two contigs if both are at least 120 bp long, to ensure that enough paired read information is available. An iterative greedy approach is used when performing scaffolding where short gaps are closed first, thus increasing the paired read information available for closing gaps (see figure 30.12).

Contigs in the same scaffold are output as one large contig with Ns inserted in between. The number of Ns inserted correspond to the estimated distance between contigs, which is calculated based on the paired read information. More precisely, for each set of paired reads spanning two contigs a distance estimate is calculated based on the supplied distance between the reads. The average of these distances is then used as the final distance estimate. The distance estimate will often be negative which happens when the paired information indicate that two contigs overlap. The assembler will attempt to align the ends of such contigs and if a high quality overlap is found the contigs are joined into a single contig. If no overlap is found, the distance estimate is set to two so that all remaining scaffolds have positive distance estimates.

Furthermore, Ns can also be present in output contigs in cases where input sequencing reads themselves contain Ns.
Performing iterative scaffolding of the shortest gaps allows long pairs to be optimally used. $i_1$ shows three contigs with dashed arches indicating potential scaffolding. $i_2$ is after first iteration when the shortest gap has been closed and long potential scaffolding has been updated. $i_3$ is the final results with three contigs in one scaffold.

Additional information about repeats being resolved using paired reads and scaffolded contigs is available as annotations on the contig sequences and as summary in the report (see section 30.2.4). This information can also be exported to the AGP format (see section 30.1.4).

The annotations in table format can be viewed by clicking the "Show Annotation Table" icon at the bottom of the Viewing Area. "Show annotation types" in the side panel allows you to select the annotation "Scaffold" among a list of other annotations. The annotations tell you about the scaffolding that was performed by the de novo assembler. That is, it tells you where particular contigs and those areas containing complete sequence information were joined together across regions without complete sequence information.

For the GFF format there are three types of annotations:

- **Scaffold** refers to the estimated gap region between two contigs where Ns are inserted.
- **Contigs joined** refers to the joining of two contigs connected by a repeat or another ambiguous structure in the graph, that was resolved using paired reads. Can also refer to overlapping contigs in a scaffold that were joined using an overlap.
- **Alternatives excluded** refers to the exclusion of a region in the graph using paired reads that resulted in a join of two contigs.

### 30.1.4 AGP export

The AGP annotations describe the components that an assembly consists of. This format can be validated by the NCBI AGP validator.

If the exporter is executed on an assembly where the contigs have been updated using a read mapping, the N’s in some scaffolds might be resolved if you select the option "Update contigs" (figure 30.13).

If the exporter encounters such a region, it will give a warning but not stop. If the exporter is executed on an assembly from GWB versions older than 6.5, it will often stop with an error saying that it encountered more than 10 N’s which wasn’t marked as a scaffold region. In this case the user would have to rerun the assembly with GWB version 6.5 or newer of the de novo assembler if they wish to be able to export to AGP.
Currently we output two types of annotations in AGP format:

- **Contig** a non-redundant sequence not containing any scaffolded regions.
- **Scaffold** the estimated gap region between two contigs.

### 30.1.5 Bubble resolution

Before the graph structure is converted to contig sequences, bubbles are resolved. As mentioned previously, a bubble is defined as a bifurcation in the graph where a path furcates into two nodes and then merge back into one. An example is shown in figure 30.14.

![Figure 30.14: A bubble caused by a heterozygous SNP or a sequencing error.](image)

In this simple case the assembler will collapse the bubble and use the route through the graph that has the highest coverage of reads. For a diploid genome with a heterozygous variant, there will be a fifty-fifty distribution of reads on the two variants, and this means that the choice of one allele over the other will be arbitrary. If heterozygous variants are important, they can be identified after the assembly by mapping the reads back to the contig sequences and performing standard variant calling. For random sequencing errors, it is more straightforward; given a reasonable level of coverage, the erroneous variant will be suppressed.

Figure 30.15 shows an example of a data set where the reads have systematic errors. Some reads include five As and others have six. This is a typical example of the homopolymer errors seen with the 454 and Ion Torrent platforms.

When these reads are assembled, this site will give rise to a bubble in the graph. This is not a problem in itself, but if there are several of these sites close together, the two paths in the graph will not be able to merge between each site. This happens when the distance between the sites is smaller than the word size used (see figure 30.16).
CHAPTER 30. DE NOVO SEQUENCING

Figure 30.15: Reads with systematic errors.

Figure 30.16: Several sites of errors that are close together compared to the word size.

In this case, the bubble will be very large because there are no complete words in the regions between the homopolymer sites, and the graph will look like figure 30.17.

Figure 30.17: The bubble in the graph gets very large.

If the bubble is too large, the assembler will have to break it into several separate contigs instead of producing one single contig.

The maximum size of bubbles that the assembler should try to resolve can be set by the user. In the case from figure 30.17, a bubble size spanning the three error sites will mean that the bubble will be resolved (see figure 30.18).

Figure 30.18: The bubble size needs to be set high enough to encompass the three sites.

While the default bubble size is often fine when working with short, high quality reads, considering the bubble size can be especially important for reads generated by sequencing platforms yielding long reads with either systematic errors or a high error rate. In such cases, a higher bubble size is recommended. For example, as a starting point, one could try half the length of the average
read in the data set and then experiment with increasing and decreasing the bubble size in small steps. For data sets with a high error rate it is often necessary to increase the bubble size to the maximum read length or more. Please keep in mind that increasing the bubble size also increases the chance of misassemblies.

### 30.1.6 Converting the graph to contig sequences

The output of the assembly is not a graph but a list of contig sequences. When all the previous optimization and scaffolding steps have been performed, a contig sequence will be produced for every non-ambiguous path in the graph. If the path cannot be fully resolved, Ns are inserted as an estimation of the distance between two nodes as explained in section 30.1.3.

### 30.1.7 Summary

So in summary, the de novo assembly algorithm goes through these stages:

- Make a table of the words seen in the reads.
- Build a de Bruijn graph from the word table.
- Use the reads to resolve the repeats in the graph.
- Use the information from paired reads to resolve larger repeats and perform scaffolding if necessary.
- Output resulting contigs based on the paths, optionally including annotations from the scaffolding step.

These stages are all performed by the assembler program.

### 30.2 De Novo Assembly

The de novo assembly algorithm of CLC Genomics Workbench offers comprehensive support for a variety of data formats, including both short and long reads, and mixing of paired reads (both insert size and orientation).

The de novo assembly process has two stages:

1. First, simple contig sequences are created by using all the information that are in the read sequences. This is the actual de novo part of the process. These simple contig sequences do not contain any information about which reads the contigs are built from. This part is elaborated in section 30.1.

2. Second, all the reads are mapped using the simple contig sequence as reference. This is done in order to show coverage levels along the contigs and to enable more downstream analysis like SNP detection and creating mapping reports. Note that although a read aligns to a certain position on the contig, it does not mean that the information from this read was used for building the contig, because the mapping of the reads is a completely separate part of the algorithm.
If you wish to only perform stage 1 above and get the simple contig sequences as output, this can be chosen when starting the de novo assembly (see section 30.2.3).

Note: The De Novo Assembly tool was optimized for genomes up to the size and complexity of the human genome. Please contact ts-bioinformatics@qiagen.com if you would like to use the De Novo assembler with genomes that are larger and more complex than the human genome. We take into account such requests to assist future features prioritization.

30.2.1 Best practices

The de novo assembler is not designed to effectively use long mate-pair read information (insert size greater than 10 kp). Such data can be incorporated but may not lead to improvements in the final results. If paired end data are being assembled, the inclusion of mate-pair information in the same assembly can sometimes lead to worse results. In such cases, we advise that the long mate-pair data is marked as single (non-paired) data before including it in the assembly (see section 6.3.7).

Before you begin the Assembly

Input Data Quality Good quality data is key to a successful assembly. We strongly recommend using the Trim Reads tool:

- Trimming based on quality can reduce the number of sequencing errors that make their way to the assembler. This reduces the number of spurious words generated during an initial assembly phase. This then reduces the number of words that will need to be discarded in the graph building stage.
- Trimming Adapters from sequences is crucial for generating correct results. Adapter sequences remaining on sequences can lead to the assembler spending considerable time trying to join regions that are not biologically relevant. In other words this can lead to the assembly taking a long time and yielding misleading results.

Input Data Quantity In the case of de novo assembly, more data does not always lead to a better result as we are more likely to observe sequencing errors in high coverage regions. This is disadvantageous because overlapping sequencing errors can result in poor assembly quality. We therefore recommend using data sets with an average read coverage less than 100x. If you expect the average coverage of your genome to be greater than 100x, you can use the Sample Reads tool to reduce coverage. To determine how many reads you need to sample to obtain a maximum average coverage of 100x, you can do the following calculation:

- Obtain an estimated size of the genome you intend to assemble.
- Multiply this genome size by 100. This value will be the total number of bases you should use as input for assembly.
- Divide the total number of bases with the average length of your sequencing reads.
- Use this number as input for the number of reads to obtain as output from the Sample Reads tool.

Running the Assembly The two parameters that can be adjusted to improve assembly quality are Word Size and Bubble Size.
The default values for these parameters can work reasonably well on a range of data sets, but we recommend that you choose and evaluate these values based on what you know about your data.

**Word Size** If you expect your data to contain long regions of high quality, a larger Word Size, such as a value above 30 is recommended. If your data has a higher error rate, as in cases when homopolymer errors are common, a Word Size below 30 is recommended. Whenever possible, the Word Size should be less than the expected number of bases between sequencing errors.

**Bubble Size** When adjusting Bubble Size, the repeat structure of your genome should be considered in conjunction with the sequence quality. If you do not expect a repetitive genome you may wish to choose a higher bubble size to improve contiguity. If you anticipate more repeats, you may wish to use a smaller Bubble Size to reduce the possibility of collapsing repeat regions. In cases where the sequence quality is not high a larger bubble size may make more sense for your data.

If you are not sure of what parameters would be best suited for your data, we recommend identifying optimal settings for your de novo assembly empirically. To do so, you may run multiple assembly jobs with different parameters and compare the results.

However, comparing the results of multiple assemblies is often a challenge. For example, you may have one assembly with a large N50 (see section 30.2.4) and another with a larger total contig length. How do you decide which is better? Is the one with the large contig sizes better or the one with more total sequence? Ultimately, the answer to these questions will depend on what the goal of your downstream analysis is. To help with this comparison, we provide some basic guidelines in the sections below.

**Evaluating and Refining the Assembly**

Three key points to look for in assessing assembly quality are contiguity, completeness, and correctness.

**Contiguity**: How many contigs are there?

A high N50 and low number of contigs relative to your expected number of chromosomes are ideal. If you aren’t sure what type of N50 and contig number might be reasonable to expect, you could try to get an idea by looking at existing assemblies of a similar genome, should these exist. For an even better sense of what would be reasonable for your data, you could make comparisons to an assembly of a similar genome, assembled using a similar amount and type of data. If your assembly results include a large number of very small contigs, it may be that you set the minimum contig length filter too low. Very small contigs, particularly those of low coverage, can generally be ignored.

**Completeness**: How much of the genome is captured in the assembly?

If a total genome length of 5MB is expected based on existing literature or similar genomes that have already been assembled, but the sum of all contig lengths is only 3.5MB, you may wish to reconsider your assembly parameters.

Two common reasons for an assembly output that is shorter than expected are:
• A Word Size that is higher than optimal for your data: A high Word Size will increase the probability of discarding words because they overlap with sequencing errors. If a word is seen only once, the unique word will be discarded even if there exist many other words that are identical except for one base (e.g., a sequencing error). A discarded word will not be considered in constructing the assembly graph and will therefore be excluded from the assembly contig sequences.

• A Bubble Size that is higher than optimal for your data: A high Bubble Size will increase the probability that two similar sequences are classified as a repeat and thus collapsed into a single contig. It is sometimes possible to identify collapsed repeats by looking at the mapping of your reads to the assembled contigs. A collapsed repeat will show as a high peak of coverage in one location.

Depending on the resources available for the organism you are working on, you might also assess assembly completeness by mapping the assembled contig sequences to a known reference. You can then check for regions of the reference genome that have not been covered by the assembled contigs. Whether this is sensible depends on the sample and reference organisms and what is known about their expected differences.

Correctness Do the contigs that have been assembled accurately represent the genome?

One key question in assessing correctness is whether the assembly is contaminated with any foreign organism sequence data. To check this, you could run a BLAST search using your assembled contigs as query sequences against a database containing possible contaminant species data. In addition to BLAST, checking the coverage can help to identify contaminant sequence data. The coverage of a contaminant contig is often different from the desired organism so you can compare the potential contaminant contigs to the rest of the assembled contigs. You may check for these types of coverage differences between contigs by:

• Map your reads used as input for the de novo assembly to your contigs (if you do not already have a mapping output);

• Create a Detailed Mapping Report;

• In the Result handling step of the wizard, check the option to Create separate table with statistics for each mapping;

• Review the average coverage for each contig in this resulting table.

If there are contigs that have good matches to a very different organism and there are discernable coverage differences, you could either consider removing those contigs from the assembly, or run a new assembly after removing the contaminant reads. One way to remove the contaminant reads would be to run a read mapping against the foreign organism’s genome and to check the option to Collect un-mapped reads. The un-mapped reads Sequence List should now be clean of the contamination. You can then use this set of reads in a new de novo assembly.

Assessing the correctness of an assembly also involves making sure the assembler did not join segments of sequences that should not have been joined - or checking for mis-assemblies. This is more difficult. One option for identifying mis-assemblies is to try running the InDels and Structural Variants tool. If this tool identifies structural variation within the assembly, that could indicate an issue that should be investigated.
Post assembly improvements

If you are working with a smaller genome, the CLC Genome Finishing Module may be of interest to you. It has been developed to help finishing small genomes, such as microbes, eukaryotic parasites, or fungi, in order to reduce the extensive workload associated with genome finishing and to facilitate as many steps in the procedure as possible. Request a free trial at https://www.qiagenbioinformatics.com/products/clc-genome-finishing-module/.

30.2.2 Randomness in the results

Different runs of the de novo assembler can result in slightly different results. This is caused by multi-threading of the program combined with the use of probabilistic data structures. If you were to run the assembler using a single thread, the effect would not be observed. That is, the same results would be produced in every run. However, an assembly run on a single thread would be very slow. The assembler should run quickly. Thus, we use multiple threads to accelerate the program.

The main reason for the assembler producing different results in each run is that threads construct contigs in an order that is correlated with the thread execution order, which we do not control. The size and "position" of a contig can change dramatically if you start building a contig from two different starting points (i.e. different words, or k-mers), which means that different assembly runs can lead to different results, depending on the order in which threads are executed. Whether a contig is scaffolded with another contig can also be affected by the order that contigs are constructed. In this case, you could see quite large differences in the lengths of some contigs reported. This will be particularly noticeable if you have an assembly with reasonably few contigs of great length.

For the moment, the output of runs may vary slightly, but the overall information content of the assembly should not be markedly different.

30.2.3 De novo assembly parameters

To start the assembly:

Toolbox | De Novo Sequencing ( ) | De Novo Assembly ( )

In this dialog, you can select one or more sequence lists or single sequences.

Click Next to set the parameters for the assembly. This will show a dialog similar to the one in figure 30.19.

At the top, you select the Word size and the Bubble size to be used. The principles of setting the word size are described in section 30.1. When using automatic calculation, you can see the word size in the History ( ) of the result files. Please note that the range of word sizes is 12-64 on 64-bit computers.

The meaning of the bubble size parameter is explained in section 30.1.5. The automatic bubble size is set to 50, unless one of the following conditions apply:

- some of the reads are from either 454, Ion torrent or PacBio;
- the reads are not all Sanger reads and average read length of all input reads is >160bp.
In these cases the bubble size is set to the average read length of all input reads. The value used is also recorded in the History of the result files.

The next option is to specify **Guidance only reads**. The reads supplied here will not be used to create the de Bruijn graph and subsequent contig sequence but only used to resolved ambiguities in the graph (see section 30.1.1 and section 30.1.3). With mixed data sets from different sequencing platforms, we recommend using sequencing data with low error rates as the main input for the assembly, whereas data with more errors should be specified only as **Guidance only reads**. This would typically be long reads or paired data sets.

You can also specify the **Minimum contig length** when doing de novo assembly. Contigs below this length will not be reported. The default value is 200 bp. For very large assemblies, the number of contigs can be huge (over a million), in which case the data structures when mapping reads back to contigs will be very large and take a very long time to handle. In this case, it is a great advantage to raise the minimum contig length to reduce the number of contigs that have to be incorporated into this data structure.

At the bottom, there is an option to **Perform scaffolding**. The scaffolding step is explained in greater detail in section 30.1.3. This will also cause scaffolding annotations to be added to the contig sequences (except when you also choose to Update contigs, see below).

Finally, there is an option to **Auto-detect paired distances**. This will determine the paired distance (insert size) of paired data sets. If several paired sequence lists are used as input, a separate calculation is done for each one to allow for different libraries in the same run. The History view of the result will list the distance used for each data set.

If the automatic detection of pairs is not checked, the assembler will use the information about minimum and maximum distance recorded on the input sequence lists (see section 6.3.7).

For mate-pair data sets with large insert sizes, it may not be possible to infer the correct paired distance. In this case, the automatic distance calculation should not be used.

The best way of checking this is to run a read mapping using the contigs from the de novo assembly as reference and the mate-pair library as reads, and then check the mapping report (see
There is a paired distance distribution graph that can be used to check whether the distance estimated by the assembler fits in the distribution found in the read mapping.

When you click **Next**, you will see the dialog shown in figure 30.20

![Figure 30.20: Parameters for mapping reads back to the contigs.](image)

There are two general types of output you can generate from the de novo assembly tool:

- **Simple contigs**: the output is a sequence list of the contigs generated.
- **Stand-alone mappings**: a read mapping is carried out after the de novo assembly, where the sequence reads used for the assembly are mapped to the contigs that were assembled.

If you choose to perform a read mapping, you can specify some parameters that are explained in section 25.1.3. The placement of reads that map in more than one position equally well are placed randomly (see section 25.1.5) and the type of gap costs used here are linear.

At the bottom, you can choose to **Update contigs** based on the subsequent mapping of the input reads back to the contigs generated by the de novo assembly. In general terms, this has the effect of updating the contig sequences based on the evidence provided by the subsequent mapping back of the read data to the de novo assembled contigs. The following are the impacts of choosing this option:

- Contig regions must be supported by at least one read mapping back to them in order to be included in the output. If more than half of the reads in a column of the mapping contain a gap, then a gap will be inserted into the contig sequence. Contig regions where no reads map will be removed. Note that if such a region occurs within a contig, it is removed and the surrounding regions are joined together.

- The most common nucleotide among the mapped reads at a given position is the one assigned to the contig sequence. In NGS data, it would be very unlikely that at a given position there would be an equal number of reads with different nucleotides. Should this occur however, then the nucleotide that comes first in the alphabet would be included in the consensus.
Note that if the "Update contigs" option is selected, the contig lengths may get below the threshold specified in figure 30.19 because this threshold is applied to the original contig sequences. If the "Update contigs" based on mapped reads option is not selected, the original contig sequences from the assembler will be preserved completely also in situations where the reads that are mapped back do not support the contig sequences.

Finally, in the last dialog of the de novo assembly, you can choose to create a report of the results.

### 30.2.4 De novo assembly report

A denovo assembly reports looks like the one shown in figure 30.21.

#### 1 Summary de novo report

#### 1.1 Nucleotide distribution

<table>

</tbody>
</table>

Figure 30.21: Creating a de novo assembly report.

The report contains the following information when both scaffolding and read mapping is performed:

**Nucleotide distribution** This includes Ns when scaffolding has been performed.

**Contig measurements** This section includes statistics about the number and lengths of contigs. When scaffolding is performed and the update contigs option is not selected, there will be two separate sections with these numbers: one including the scaffold regions with Ns and one without these regions.

- **N25, N50 and N75** The N25 contig set is calculated by summarizing the lengths of the biggest contigs until you reach 25 % of the total contig length. The minimum contig length in this set is the number that is usually used to report the N25 value of a de novo assembly. The same goes with N50 and N75 which are the 50 % and 75 % of the total contig length, respectively.

- **Minimum, maximum and average** This refers to the contig lengths.
• **Count** The total number of contigs.
• **Total** The number of bases in the result. This can be used for comparison with the estimated genome size to evaluate how much of the genome sequence is included in the assembly.

**Accumulated contig lengths** This shows the summarized contig length on the y axis and the number of contigs on the x axis, with the biggest contigs ranked first. This answers the question: how many contigs are needed to cover e.g. half of the genome.

If the de novo assembly was followed by a read mapping, it is possible to have the following additional sections.

**Summary statistics** Gives the count, average length and total bases amount for all reads, matched and non-matched reads, contigs, reads in pairs, and broken paired reads.

**Distribution of read length** For each sequence length, you can see the number of reads and the distribution in percent. This is mainly useful if you don’t have too much variance in the lengths as in Sanger sequencing data for example.

**Distribution of matched read length** Equivalent to the above, except that this includes only the reads that have been matched to a contig.

**Distribution of non-matched read length** Shows the distribution of lengths of the unmapped sequences.

**Paired reads distance distribution** Shows the distribution of paired reads distances.

For a more detailed report, use the QC for Read Mapping tool, and see the description of the report in section 27.1.2.

### 30.2.5 De novo assembly output

**Stand-alone mapping.** The de novo assembly is followed by a step where the reads used to generate the contigs are mapped against the contigs, using them as reference.

This output is called assembly and opens as a table listing all contigs as seen in figure 30.22.

The information included in the table is:

• **Name.** When mapping reads to a reference, this will be the name of the reference sequence.

• **Consensus length.** The length of the consensus sequence. Subtracting this from the length of the reference will indicate how much of the reference that has not been covered by reads.

• **Total read count.** The number of reads. Reads with multiple hits on different reference sequences are placed according to your input for Non-specific matches

• **Single reads** and **Reads in pair.** Total number of reads, single and/or in pair.

• **Average coverage.** This is simply summing up the bases of the aligned part of all the reads divided by the length of the reference sequence.
Reference sequence. The name of the reference sequence.

Reference length. The length of the reference sequence.

Reference common name and Reference latin name. Name, common name and Latin name of each reference sequence.

At the bottom of the table there are three buttons that can be used to open or extract sequences. Select the relevant rows before clicking on the buttons:

- **Open Mapping.** Opens the read mapping for visual inspection. You can also open one mapping simply by double-clicking in the table.

- **Extract Consensus/Contigs.** For de novo assembly results, the contig sequences will be extracted. For results when mapping against a reference, the Extract Consensus tool will be used (see section 25.6).

- **Extract Subset.** Creates a new mapping table with the mappings that you have selected.

Double clicking on a contig name will open the read mapping in split view.

It is possible to open the assembly as an annotation table (using the icon highlighted in figure 30.22). The annotations available in the table are the following (see figure 30.23):

- **Alternatives Excluded.** More than one path through the graph was possible in this region but evidence from paired data suggested the exclusion of one or more alternative routes in favour of the route chosen.
• **Contigs Joined.** More than one route was possible through the graph such that an unambiguously choice of how to traverse the graph cannot be made. However evidence from paired data supports one of these routes and on this basis, this route is selected (and other routes excluded).

• **Scaffold.** The route through the graph is not clear but evidence from paired data supports the connection of two contigs. A single contig is then reported with N characters between the two connected regions. This entity is also known as a scaffold. The number of N characters represents the expected distance between the regions, based on the evidence the paired data.

![Figure 30.23: A de novo assembly read mapping seen as annotation table.](image)

Using the menu in the right end side panel, it is possible to select only one type of annotations to be displayed in the table.

**Simple contigs.** The output is a sequence list of the contigs generated (figure 30.24), that can also be seen as a table and an annotation table as described for the stand-alone read mapping described above.

### 30.3 Map Reads to Contigs

The Map Reads to Contigs tool allows mapping of reads to contigs. This can be relevant in situations where the reference of a mapping is contigs, such as when:

- Contigs have been imported from an external source
- The output from a de novo assembly is contigs with no read mapping
- You wish to map a new set of reads or a subset of reads to the contigs

The Map Reads to Contigs tool is similar to the Map Reads to Reference tool in that both tools accept the same input reads, and make use of the same read mapper in accordance to the reads input (see the introduction of section 25.1).
The main difference between the two tools is the output. The output from the Map reads to contigs tool is a de novo object that can be edited, in contrast to the reference sequence used when mapping reads to a reference.

To run the Map Reads to Contigs tool:

**Toolbox | De Novo Sequencing ( ) | Map Reads to Contigs ( )**

This opens up the dialog in figure 30.25 where you select the reads you want to map to the contigs. Click Next.

Select the contigs to map the reads against (figure 30.26).

Under "Contig masking", specify whether to include or exclude specific regions (for a description of this see section 25.1.2).

The contigs can be updated by selecting "Update contigs" at the bottom of the wizard. The advantage of using this option during read mapping is that the read mapper is better than the de novo assembler at handling errors in reads. Specifically, the actions taken when contigs are updated are:

- Regions of a contig reference, where no reads map, are removed. This leads to a joining of the surrounding regions of the contig as shown in the example in figure 30.27).
- In the case of locations where reads map to a contig reference, but there are some
mismatches to that contig, the contig sequence is updated to reflect the majority base at that location among the reads mapped there. If more than half of the reads contain a gap at that location, the contig sequence will be updated to include the gap.

![Before the contig is updated:](reference)

<table>
<thead>
<tr>
<th>Reference:</th>
<th>AACCTT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Read 1</td>
<td>AA</td>
</tr>
<tr>
<td>Read 2</td>
<td>TT</td>
</tr>
</tbody>
</table>

![After the contig is updated:](reference)

<table>
<thead>
<tr>
<th>Reference:</th>
<th>AATT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Read 1</td>
<td>AA</td>
</tr>
<tr>
<td>Read 2</td>
<td>TT</td>
</tr>
</tbody>
</table>

Figure 30.27: When selecting "Update Contig" in the wizard, contigs will be updated according to the reads. This means that regions of a contig where no reads map will be removed.

In the Mapping options dialog, the parameters of the Map Reads to Contigs tool are identical to the ones described for the Map Reads to Reference tool (see section 25.1.3).

The output from the Map Reads to Contigs tool can be a track or stand-alone read mappings as selected in the last dialog.

When stand-alone read mappings have been selected as output, it is possible to edit and delete contig sequences.

Figure 30.28 shows two stand-alone read mappings generated by using Map Reads to Reference (top) and Map Reads to Contigs (bottom) on the exact same reads and contigs as input. Contig 1 from both analyses have been opened from their respective Contig Tables. The differences are highlighted with red arrows. The output from the Map Reads to Reference has a consensus sequence; in the output from Map Reads to Contigs, the Contig itself is the consensus sequence if "Update contigs" was selected.
Figure 30.28: Two different read mappings performed with "Map Reads to Reference" (top) and "Map Reads to Contigs" (bottom). The differences are highlighted with red arrows.
Chapter 31

Epigenomics analysis

31.1 ChIP-Seq Analysis

Chromatin immunoprecipitation followed by high-throughput sequencing (ChIP-Seq) is a method for analyzing DNA-protein interactions. Peak finding is an essential post-processing step in the analysis and interpretation of ChIP-Seq data and many tools that have been developed specifically for this purpose.

Most peak callers are difficult to parametrize such that they accurately discriminate active and inactive promoter regions [Rye et al., 2011, Heydarian et al., 2014]. Nevertheless, these peaks are clearly visible to the human eye since they show a distinct shape. The ChIP-Seq Analysis tool takes a different approach, which is conceptually intuitive and modular by learning the shape of the signal from the data. The parametrization is done by giving positive and negative examples of peak shapes, making the parametrization process explicit and easily understandable.

The ChIP-Seq Analysis tool uses this approach to identify genomic regions with significantly enriched read coverage and a read distribution with a characteristic shape.

ChIP-Seq data analysis is typically based on identification of genomic regions where the signal (i.e. number of mapped reads) is significantly enriched. The detection of the enrichment is based on a background model or the comparison with a ChIP-Seq sample where the immunoprecipitation
step is omitted. The shape of the signal from ChIP-Seq data depends on which protein was targeted in the immunoprecipitation reaction [Stanton et al., 2013, Kumar et al., 2013]. For example, the typical signal shape of a transcription factor binding site like NRSF shows a high concentration of forward reads followed by a high concentration of reverse reads (figure 31.1).

Figure 31.1: Distribution of forward (green) and reverse (red) reads around a binding site of the transcription factor NRSF.

The tool makes use of this characteristic shape to identify enriched regions (peaks) in ChIP-Seq data.

### 31.1.1 Quality Control of ChIP-Seq data

During the first step of the analysis, the ChIP-Seq Analysis tool analyzes the input to check if the input data satisfy the assumptions made by the algorithm and to compute several quality measures. The cross-correlation between reads mapping in the forward and in the reverse strand is often used to investigate the quality of ChIP-Seq experiments [Landt et al., 2012, Marinov et al., 2014]. The quality is determined with respect to the two main peaks of the cross-correlation plot (figure 31.2), the peak at the read length (often called a phantom peak [Landt et al., 2012]) and the one at the fragment length. The peak at the fragment length is typically higher than the peak at the read length and the background (figure 31.2) for successful ChIP-Seq experiments.

Figure 31.2: Difference in cross-correlation profiles in ChiP experiments of good and low quality.

For each input file of the analysis, the ChIP-Seq Analysis tool calculates and reports several quality measures. Those quality measures have been investigated by the modENCODE consortium and are described in more detail in [Landt et al., 2012]. The quality measures are:

**Number of mapped reads** For mammalian cells (e.g. human and mouse), this value should be at least 10 million reads. For smaller organisms such as worm and fly, this value should be at least 2 million reads.
Normalized strand coefficient The normalized strand coefficient describes the ratio between the fragment-length peak and the background cross-correlation values. This value should be greater than 1.05 for ChIP-Seq experiments.

Relative strand correlation The relative strand correlation describes the ratio between the fragment-length peak and the read-length peak in the cross-correlation plot. This value should be high (at least 0.8) for transcription factor binding sites, which have a concentrated signal. However, this value can be low even for successful ChIP-Seq experiments on histone modifications [Landt et al., 2012].

31.1.2 Learning peak shapes
In order to learn a characteristic shape from ChIP-Seq data, the ChIP-Seq Analysis tool analyzes the genomic coverage of the reads. For each read mapping, the 5’ position of the reads mapping in the forward strand and the 3’ position of the reads mapping in the reverse strand are extracted. Those values are then normalized to create a coverage value for the forward and the reverse strand. In order to learn the characteristic peak shape of ChIP-Seq data, the ChIP-Seq Analysis tool identifies a set of positive regions, i.e. regions with very apparent peaks. Those regions are easy to find and are typically found by every peak-caller. The ChIP-Seq Analysis tool identifies these regions by finding areas with very high coverage in the ChIP-Seq data. The average shape of the positive regions of the NRSF transcription factor is shown in for the forward and reverse strand in figure 31.3.

![Figure 31.3: Average peak shape of the transcription factor NRSF.](image-url)

Next, the ChIP-Seq Analysis tool builds a filter, which can be used to identify genomic regions whose read coverage profile matches the characteristic peak shape and to determine the statistical significance of this match. In order to build such a filter, examples of positive (e.g. ChIP-Seq peaks) and negative (e.g. background noise, PCR artifacts) profiles are needed as input. The ChIP-Seq Analysis tool uses regions with very high coverage in the experiment ChIP-Seq as positive examples. If control ChIP-Seq experiments are given, regions with high coverage in the control and low in the experimental ChIP-Seq data are used as negative examples, as they are probably originated from PCR artifacts. If there is no information to build a negative profile from, the profile is estimated from the sequencing noise.

Once the positive and negative regions have been identified, the ChIP-Seq Analysis tool learns a filter that matches the average peak shape, which we term peak shape filter. The filter implemented is called Hotelling Observer and was chosen because it is the matched filter that
maximizes the AUCROC (Area Under the Curve of the Receiver Operator Characteristic), one of the most widely used measures for algorithmic performance.

The Hotelling observer $h$ is defined as:

$$h = \left( \frac{R_p + R_n}{2} \right)^{-1} \left( \mathbb{E}[X_p] - \mathbb{E}[X_n] \right),$$

(31.1)

where $\mathbb{E}[X_p]$ is the average profile of the positive regions, $\mathbb{E}[X_n]$ is the average profile of the negative regions, while $R_p$ and $R_n$ denote the covariance matrices between the positive and negative profiles, respectively. The Hotelling Observer has already previously been successfully used for calling ChIP-Seq peaks [Kumar et al., 2013]. An example of Hotelling observer is shown in figure 31.4.

![Figure 31.4](image)

**Figure 31.4:** Peak shape filter for the transcription factor NRSF.

### 31.1.3 Applying peak shape filters to call peaks

The peak shape filter is then applied to the experimental data and a score is calculated at each genomic position. The score is obtained by extracting the genomic coverage profile of a window centered at the genomic position and then comparing this profile to the peak shape filter. The result of this comparison is defined as peak shape score. The peak shape score is standardized and follows a standard normal distribution, so a p-value for each genomic position can be calculated as $p-value = \Phi(-\text{Peak shape score of the peak center})$, where $\Phi$ is the standard normal cumulative distribution function.

Once the peak shape score for the complete genome is calculated, peaks are identified as genomic regions where the maximum peak shape score is greater than a given threshold. The center of the peak is then identified as the genomic region with the highest peak shape score and the boundaries are determined by the genomic positions where the peak shape score becomes negative.

### 31.1.4 Running the Transcription Factor ChIP-Seq tool

To run the Transcription Factor ChIP-Seq tool:

**Toolbox | Epigenomics Analysis ( ) | Transcription Factor ChIP-Seq ( )**

This will open up the wizard shown in figure 31.5 where you can select the input data (the mapped ChIP-Seq reads). Multiple inputs (e.g. replicate experiments) are accepted, provided that
they refer to the same genome. Track based read mappings (①) and stand-alone read mappings (②) / (③) are both accepted.

![Figure 31.5: Select the input data for the Transcription Factor ChIP-Seq tool.](image)

Click on the button labeled Next to go to the next wizard step (shown in figure 31.6).

![Figure 31.6: Options for the Transcription Factor ChIP-Seq tool.](image)

In this wizard step you have the following options:

- **Control data** The control data, typically a ChIP-Seq sample where the immunoprecipitation step is omitted, can be specified in this option.

- **Maximum P-value for peak calling** The threshold for reporting peaks can be specified by this option.

Click on the button labeled Next to go to the wizard step shown in figure 31.7.

In addition to the annotation track with Peak annotations (④) that will always be generated by the algorithm, you can choose to select additional output types.

The options are:

- **QC report** (⑤) Generates a quality control report that allows you to check the quality of the reads. The QC report contains metrics about the quality of the ChIP-Seq experiment. It lists the number of mapped reads, the normalized strand coefficient, and the relative strand correlation for each mapping. For each metric, the Status column will be **OK** if the experiment has good quality or **Low** if the metric is not as high as expected. Furthermore, the QC report will show the mean read length, the inferred fragment length, and the window size that the algorithm would need to be able to model the signal shape. In case the input contains paired-end reads, the report will also contain the empirical fragment length distribution. The metrics and their definitions are described in more detail in section 31.1.1.
Figure 31.7: Output options for the Transcription Factor ChIP-Seq tool.

- **Peak shape filter** ( ) The peak shape filter contains the Hotelling Observer filter that was learned by the Transcription Factor ChIP-Seq algorithm. For the definition of Peak shape, see section 31.1.3.

- **Peak shape score** ( ) A graph track containing the peak shape score. The track shows the peak shape score for each genomic position. To save disk space, only peak shape scores greater than zero are reported. For the definition of peak shape score, see section 31.1.3.

Choose whether you want to open the results directly, or save the results in the **Navigation Area**. If you choose to save the results, you will be asked to specify where you would like to save them.

**Peak track**

The main result of the Transcription Factor ChIP-Seq algorithm is an annotation track containing the peaks. For each peak the following quantities are reported in the table, which can be opened by clicking on the table icon ( ) in the lower left corner of the peak annotation track. For more details on some of the values included in the table, see section 31.1.3.

- **Chromosome** The chromosome where the peak is located.
- **Region** The position of the peak.
- **Center of peak** The center position of the peak. This is determined as the genomic position that matches the peak shape filter best.
- **Length** The length of the peak.
- **Peak shape score** The peak shape score of the peak.
- **P-value** The p-value of the peak.

The peak annotation track is most informative when combined with the read mapping in a Track List (you can see how to create a track list here: [http://resources.qiagenbioinformatics.com/manuals/clcgenomicsworkbench/current/index.php?manual=Track_lists.html](http://resources.qiagenbioinformatics.com/manuals/clcgenomicsworkbench/current/index.php?manual=Track_lists.html)).
A Track List containing the mapped reads, the Peak track, and the Peak shape score track is shown in figure 31.8.

![Figure 31.8: Inspection of the result of the Transcription Factor ChIP-Seq tool.](image)

Note that if you make a split view of the table and the peak annotation track (by holding down the Ctrl key (Cmd on Mac) while clicking on the table icon in the lower left corner of the peak annotation track), you will be able to browse through the peaks by clicking in the table, as the peak annotation track and the table are connected. As a result the view will jump to the position of the peak selected in the table.

### 31.2 Annotate with nearby gene information

This tool will create a copy of the annotation track used as input and add information about nearby genes.

![Toolbox | Epigenomics Analysis | Annotate with Nearby Gene Information](image)

First, select the track you wish to annotate and click Next. The tool was designed for ChIP-Seq analysis, but you can choose any kind of annotation track as input. Next, select a gene track with a compatible genome (figure 31.9).

![Figure 31.9: Select gene track.](image)

The result of this tool is a new annotation track with all the annotations from the input track and with additional information about nearby genes and four columns will be added to the table view:
• **5’ gene** The name of the nearest upstream gene.

• **5’ distance** The distance from the nearest upstream gene or 0 if the feature overlaps the nearest gene. The distance value is determined by the shortest distance between an end of the gene annotation and an end of the peak annotation, regardless of the annotation orientation (see figure 31.10).

• **3’ gene** The name of the nearest downstream gene.

• **3’ distance** The distance from the nearest downstream gene or 0 if the feature overlaps the nearest downstream gene. The distance value is determined by the shortest distance between an end of the gene annotation and an end of the peak annotation, regardless of the annotation orientation.

![Figure 31.10: The figure is a split view between a table view and a track list showing the gene annotation track, the ChIP-Seq reads, and the annotated ChIP peaks. The red arrows and numbers illustrate the 5’ distance and 3’ distance.](image)

### 31.3 Bisulfite Sequencing

#### 31.3.1 Detecting DNA methylation

DNA-Methylation is one of the most significant epigenetic mechanisms for cell-programming. DNA-methylation alters the gene expression pattern such that cells can recall their cell type, essentially removing the necessity for continuous external signalling or stimulation. Even more, DNA-methylation is retained throughout the cell-cycle and thus inherited through cell division. DNA-Methylation involves the addition of a methyl group to the 5-position of the cytosine pyrimidine ring or the number 6 nitrogen of the adenine purine ring. DNA-methylation at the 5-position of cytosines typically occurs in a CpG dinucleotide context. CpG dinucleotides are often grouped in clusters called CpG islands, which are present in the 5’ regulatory regions of many genes.
A large body of evidence has demonstrated that aberrant DNA-methylation is associated with unscheduled gene silencing, resulting in a broad range of human malignancies. Aberrant DNA-methylation manifests itself in two distinct forms: hypomethylation (a loss/reduction of methylation) and hypermethylation (an increase in methylation) compared to normal tissue. Hypermethylation has been found to play significant roles in carcinogenesis by repressing transcription of tumor suppressor genes, while hypomethylation is implicated in the development and the progression of cancer.

DNA methylation detection methods comprise various techniques. Early methods were based on restriction enzymes, cleaving either methylated or unmethylated CpG dinucleotides. These were laborious but suitable to interrogate the DNA-methylation status of individual DNA sites. It was later discovered that bisulfite treatment of DNA turns unmethylated cytosines into uracils while leaving methylated cytosines unaffected (figure 31.11). This discovery provided a more effective screening method that, in conjunction with whole genome shotgun sequencing of bisulfite converted DNA, opened up a broad field of genome-wide DNA methylation studies. Ever since, bisulfite shotgun sequencing (BS-seq) is considered a gold-standard technology for genome-wide methylation profiling at base-pair resolution.

Figure 31.11: Outline of bisulfite conversion of sample sequence of genomic DNA. Nucleotides in blue are unmethylated cytosines converted to uracils by bisulfite, while red nucleotides are 5-methylcytosines resistant to conversion. Source: https://en.wikipedia.org/wiki/Bisulfite_sequencing

Figure 31.12 depicts the conceptual steps of the Bisulfite-sequencing:

1. **Genomic DNA** Genomic DNA is extracted from cells, sheared to fragments, end-repaired, size-selected (around 400 base pairs depending on targeted read length) and ligated with Illumina methylated sequencing adapters. End-repair involves either methylated or unmethylated cytosines, possibly skewing true methylation levels. Therefore, 3’- and 5’-ends of sequenced fragments should be soft-clipped prior to assessing methylation levels.

2. **Denaturation** Fragments must be denatured (and kept denatured during bisulfite conversion), because bisulfite can only convert single-stranded DNA.

3. **Bisulfite conversion** Bisulfite converts unmethylated cytosines into uracils, but leaves
Figure 31.12: Individual steps of BS-seq workflow include denaturation of fragmented sample DNA, bisulfite conversion, subsequent amplification, sequencing and mapping of resulting DNA-fragments. (See text for explanations). Methylated cytosines are drawn in red, unmethylated cytosines and respective uracils/thymidines in blue. DNA-nucleotides that are in-silico converted (during read mapping) are given in green.

methylated cytosines unchanged. Because bisulfite conversion has degrading effects on the sample DNA, the conversion duration is kept as short as possible, sometimes resulting in non-complete conversions (i.e. not all unmethylated cytosines are converted).

4. **PCR amplification** PCR-amplification reconstructs the complementary strands of the converted single-stranded fragments and turns uracils into thymines.

5. **Strand discordance** Not an actual step of the workflow, but to illustrate that bisulfite converted single-stranded fragments are not reverse-complementary anymore after conversion.

6. **Paired-end sequencing** Directional paired-end sequencing yields read pairs from both strands of the original sample-DNA. The first read of a pair is known to be sequenced
either from the original-top (OT) or the original-bottom (OB) strand. The second read of a pair is sequenced from a complementary strand, either ctOT or ctOB. It is a common misunderstanding that the first read of a pair yields methylation information for the top-strand and the second read for the bottom-strand (or vice versa). Rather, both reads of a read pair report methylation for the same strand of sample DNA, either the top or the bottom strand. Individual read pairs can of course arise from both the top and the bottom strand, eventually yielding information for both strands of the sample DNA.

7. **In silico read-conversion** The only bias-free mapping approach for BS-seq reads involves *in-silico* conversion of all reads. All cytosines within all first reads of a pair are converted to thymines and all guanines in all second reads of a pair are converted to adenines (complementary to C-T conversion).

8. **Mapping to CT- or GA-conversion of reference genome** The reference genome is also converted into two different *in silico* versions. In the first conversion all cytosines are replaced by thymines and, in the second conversion, all guanines are converted to adenines. The *in silico* converted read pairs are then independently mapped to the two conversions of the reference genome and the better of the two mappings is reported as final mapping result (see green checkboxes).

Note: with non-directional BS-seq, no assumptions regarding the strand origins of either of the reads of a pair can be made (see step 6). Therefore, two different conversions of the read pair need to be created: the first read of a converted pair consists of the CT-conversion of read 1 and the GA-conversion of read 2, and the second converted pair consists of the GA-conversion of read 1 and the CT-conversion of read 2. Both converted reads pairs are subsequently mapped to the two conversion of the reference genome. The best out of the four resulting mappings is then reported as the final mapping result.

### 31.3.2 Map Bisulfite Reads to Reference

Setting up the **Map Bisulfite Reads to Reference** tool is very similar to the usual read mapping, with a few differences. In particular,

- Some options such as ’Global alignment’ are either not available or preset.
- Only a track version of mappings is produced in output.
- The bisulfite mappings in CLC Workbenches have a special ’invisible’ property set for them, to inform the downstream tool **Call Methylation levels** (See section 31.3.3) about the correct type of input.

Please note that, because two versions of the reference sequence (C->T and G->A - converted) have to be indexed and used simultaneously for each read, the RAM requirements for the bisulfite mapper are double than those needed for a regular mapping against a reference sequence of the same size.

To start the read mapping:
Selecting reads and directionality

In the first dialog, select the sequences or sequence lists containing the sequencing data (figure 31.13). Please note that reads longer than 100,000 bases are not supported.

Figure 31.13: Specifying the reads as input. You can also choose to work in batch.

When the sequences are selected, click Next to specify what type of protocol you have used (directional or not).

A directional protocol yields reads from both strands of the original sample-DNA. The first read of a pair (or every read for single-end sequencing) is known to be sequenced either from the original-top (OT) or the original-bottom (OB) strand. The second read of a pair is sequenced from a complementary strand, either ctOT or ctOB. At the time of writing, examples of directional protocols include:

- Illumina TruSeq DNA Methylation Kit (formerly EpiGnome)
- Kits from the NuGen Ovation family of products
- Swift Accel-NGS Methyl-seq DNA Library Kit
- Libraries prepared by the 'Lister’ method

In a non-directional protocol, the first read of a pair may come from any of the four strands: OT, OB, ctOT or ctOB. Examples include:

- Zymo Pico Methyl-Seq Library Kit
- Bioo Scientific (Perkin Elmer) NEXTflex Bisulfite-Seq Kit
- Libraries prepared by the 'Cokus’ method

If you are uncertain about the directionality of your protocol, contact the protocol vendor. Note that it is sometimes possible to infer the directionality by looking at the reads: in the absence of methylation, a directional protocol will have few or no Cs in the first read of each pair. We do not recommend however using this approach.

Selecting the reference

When the sequences and directionality are selected, click Next, and you will see the dialog shown in figure 31.14.

Click the Browse and select element button to select either single sequences, a list of sequences or a sequence track as reference. Note the following constraints:
single reference sequences longer than 2gb \((2 \cdot 10^9)\) bases) are not supported.
• a maximum of 120 input items (sequence lists or sequence elements) can be used as input to a single read mapping run.

Including or excluding regions (masking)

The next part of the dialog shown in figure 31.14 lets you mask the reference sequences. Masking refers to a mechanism where parts of the reference sequence are not considered in the mapping. This can be useful for example when mapping data is captured from specific regions (e.g. for amplicon resequencing). The read mapping will still base its output on the full reference - it is only the core read mapping that ignores regions.

Masking is performed by discarding the masked out nucleotides. As a result the reference is split into separate sequences, which are positioned according to the original unmasked reference sequence.

Note that you should be careful that your data is indeed only sequenced from the target regions. If not, some of the reads that would have matched a masked-out region perfectly may be placed wrongly at another position with a less-perfect match and lead to wrong results for subsequent variant calling. For resequencing purposes, we recommend testing whether masking is appropriate by running the same data set through two rounds of read mapping and variant calling: one with masking and one without. At the end, comparing the results will reveal if any off-target sequences cause problems in the variant calling.

Masking out repeats or using other masks with many regions is not recommended. Repeats are handled well and does not cause any slowdown. On the contrary, masking repeats is likely to cause a dramatic slowdown in speed, increase memory requirements and lead to incorrect read placement.

To mask a reference sequence, first click the Include or Exclude options, and second click the Browse button to select a track to use for masking.

Mapping parameters

Clicking Next leads to the parameters for the read mapping (see figure 31.15). The first parameter allows the mismatch cost to be adjusted:
Figure 31.15: Setting parameters for the bisulfite read mapping.

- **Match score** The positive score for a match between the read and the reference sequence. It is set by default to 1 but can be adjusted up to 10.

- **Mismatch cost** The cost of a mismatch between the read and the reference sequence. Ambiguous nucleotides such as "N", "R" or "Y" in read or reference sequences are treated as mismatches and any column with one of these symbols will therefore be penalized with the mismatch cost.

After setting the mismatch cost you need to choose between linear gap cost and affine gap cost, and depending on the model you chose, you need to set two different sets of parameters that control how gaps in the read mapping are penalized.

- **Linear gap cost** The cost of a gap is computed directly from the length of the gap and the insertion or deletion cost. This model often favors small, fragmented gaps over long contiguous gaps. If you choose linear gap cost, you must set the insertion cost and the deletion cost:

  - **Insertion cost** The cost of an insertion in the read (a gap in the reference sequence). The cost of an insertion of length $\ell$ will be
    \[
    \ell \cdot \text{Insertion cost},
    \]
  
  \[\text{(31.2)}\]

  - **Deletion cost** The cost of a deletion in the read (gap in the read sequence). The cost of a deletion of length $\ell$ will be
    \[
    \ell \cdot \text{Deletion cost}.
    \]
  
  \[\text{(31.3)}\]

- **Affine gap cost** An extra cost associated with opening a gap is introduced such that long contiguous gaps are favored over short gaps. If you chose affine gap cost, you must also set the cost of opening an insertion or a deletion:

  - **Insertion open cost** The cost of opening an insertion in the read (a gap in the reference sequence).
**Insertion extend cost** The cost of extending an insertion in the read (a gap in the reference sequence) by one column.

**Deletion open cost** The cost of a opening a deletion in the read (gap in the read sequence).

**Deletion extend cost** The cost of extending a deletion in the read (gap in the read sequence) by one column.

Using, affine gap cost, an insertion of length \( \ell \) is penalized by

\[
\text{Insertion open cost} + \ell \cdot \text{Insertion extend cost},
\]

and a deletion of length \( \ell \) is penalized by

\[
\text{Deletion open cost} + \ell \cdot \text{Deletion extend cost}.
\]

In this way long consecutive gaps get a lower cost per column than small fragmented gaps and they are therefore favored.

The score of a match between the read and the reference is usually set to 1. Adjusting the cost parameters above can improve the mapping quality, e.g. when the read error rate is high or the reference is expected to differ significantly from the sequenced organism. For example, if the reads are expected to contain many insertions and/or deletions, it can be a good idea to lower the insertion and deletion costs to allow more of such errors. However, one should also consider the possible drawbacks when adjusting these settings. For example, reducing the insertion and deletion cost increases the risk of mapping reads to the wrong positions in the reference.

![Figure 31.16: An alignment of a read where a region of 35bp at the start of the read is unaligned while the remaining 57 nucleotides matches the reference.](image)

Figure 31.16 shows an example using linear gap cost where the read mapper is unable to map a region in a read due to insertions in the read and mismatches between the read and the reference. The aligned region of the read has a total of 57 matching nucleotides which result in an alignment score of 57 which is optimal when using the default cost for mismatches and insertions/deletions (2 and 3 respectively). If the mapper had aligned the remaining 35bp of the read as shown in figure 31.17 using the default scoring scheme, the score would become:

\[
(26 + 1 + 3 + 57) \times 1 - 5 \times 2 - 8 \times 3 = 53
\]

In this case, the alignment shown in Figure 31.16 is optimal since it has the highest score. However, if either the cost of deletions or mismatches were reduced by one, the score of the alignment shown in figure 31.17 would become 61 and 58, respectively, and thus make it optimal.

Once the optimal alignment of the read is found, based on the cost parameters described above, a filtering process determines whether this match is good enough for the read to be included in the output. The filtering threshold is determined by two factors:
Figure 31.17: An alignment of a read containing a region with several mismatches and deletions. By reducing the default cost of either mismatches or deletions the read mapper can make an alignment that spans the full length of the read.

- **Length fraction** The minimum percentage of the total alignment length that must match the reference sequence at the selected similarity fraction. A fraction of 0.5 means that at least half of the alignment must match the reference sequence before the read is included in the mapping (if the similarity fraction is set to 1). Note, that the minimal seed (word) size for read mapping is 15 bp, so reads shorter than this will not be mapped.

- **Similarity fraction** The minimum percentage identity between the aligned region of the read and the reference sequence. For example, if the identity should be at least 80% for the read to be included in the mapping, set this value to 0.8. Note that the similarity fraction relates to the length fraction, i.e. when the length fraction is set to 50% then at least 50% of the alignment must have at least 80% identity (see figure 31.18).

Figure 31.18: A read containing 59 nucleotides where the total alignment length is 60. The part of the alignment that gave rise to the optimal score has length 58 which excludes 2 bases at the left end of the read. The length fraction of the matching region in this example is therefore 58/60 = 0.97. Given a minimum length fraction of 0.5, the similarity fraction of the alignment is computed as the maximum similarity fraction of any part of the alignment which constitute at least 50% of the total alignment. In this example the marked region in the alignment with length 30 (50% of the alignment length) has a similarity fraction of 0.83 which will satisfy the default minimum similarity fraction requirement of 0.8.

**Mapping paired reads**

- **Global alignment** By default, mapping is done with local alignment of the reads to the reference. The advantage of performing local alignment instead of global alignment is that the ends are automatically left unaligned if there are many differences from the reference at the ends. For many sequencing platforms, the quality of the bases drop along the read, and a local alignment approach is desirable. By checking this option, the mapper is forced to look for the highest scoring alignment of the entire read, meaning that the read mapping generated will have no unaligned ends even when the end of the reads align to the wrong places.

- **Auto-detect paired distances** If the sequence list used as input contains paired reads,
this option will automatically be enabled - if it contains single reads, this option will not be applicable.

CLC Genomics Workbench offers as the default choice to automatically calculate the distance between the pairs. If this is selected, the distance is estimated in the following way:

1. A sample of 100,000 reads is extracted randomly from the full data set and mapped against the reference using a very wide distance interval.
2. The distribution of distances between the paired reads is analyzed, and an appropriate distance interval is selected:
   - If less than 10,000 reads map, a simple calculation is used where the minimum distance is one standard deviation below the average distance, and the maximum distance is one standard deviation above the average distance.
   - If more than 10,000 reads map, a more sophisticated method is used which investigates the shape of the distribution and finds the boundaries of the peak.
3. The full sample is mapped using this distance interval.
4. The history of the result records the distance interval used.

The above procedure will be run for each sequence list used as input, assuming that they do not necessarily share the same library preparation and could have different distributions of paired distances. Figure 31.19 shows an example of the distribution of intervals with and without automatic pair distance interval estimation.

![Figure 31.19: To the left: mapping with a narrower distance interval estimated by the workbench. To the right: mapping with a large paired distance interval (note the large right tail of the distribution).](image)

Sometimes the automatic estimation of the distance between the pairs may return a warning "multiple intervals detected". This may happen if the reads derive from multiple libraries or from certain types of amplicon sequencing protocols. In this case, the estimates may still be correct, but, if in doubt, the user may want to disable the option to automatically estimate paired distances and instead manually specify minimum and maximum distances between pairs on the input sequence list.

If the automatic detection of paired distances is not checked, the mapper will use the information about minimum and maximum distance recorded on the input sequence lists. The "automatic detection of paired distance" option when mapping should be used with caution. It is possible that the estimated distance setting is too narrow and consequently many read pairs will be flagged broken.
When a paired distance interval is set, the following approach is used for determining the placement of read pairs:

- First, all the optimal placements for the two individual reads are found.
- Then, the allowed placements according to the paired distance interval are found.
- If both reads can be placed independently but no pairs satisfies the paired criteria, the reads are treated as independent and marked as a **broken pair**.
- If only one pair of placements satisfy the criteria, the reads are placed accordingly and marked as uniquely placed even if either read may have multiple optimal placements.
- If several placements satisfy the paired criteria, the pair is treated as a non-specific match (see section 25.1.5 for more information.)
- If one read is uniquely mapped but the other read has several placements that are valid given the distance interval, the mapper chooses the location that is closest to the first read.

### Non-specific matches

At the bottom of the dialog, you can specify how **Non-specific matches** should be treated. The concept of Non-specific matches refers to a situation where a read aligns at more than one position with an equally good score. In this case you have two options:

- **Random**: This will place the read in one of the positions randomly.
- **Ignore**: This will not include the read in the final mapping.

Note that a read is only considered non-specific when the read matches equally well at several alignment positions. If there are e.g. two possible alignment positions and one of them is a perfect match and the other involves a mismatch, the read is placed at the position with the perfect match and it is not marked as a non-specific match.

For paired data, reads are only considered non-specific matches if the entire pair could be mapped elsewhere with equal scores for both reads, or if the pair is broken in which case a read can be categorized as non-specific in the same way as single reads (see section 25.1.4).

When looking at the mapping, the default color for non-specific matches is yellow.

### Gap placement

In the case of insertions or deletions in homopolymeric or repetitive regions, the precise placement of the insertion or deletion cannot be determined from the data. An example is shown in figure 31.20.

In this example, three A’s in the reference (top) have been replaced by two A’s in the reads (shown in red). The gap is placed towards the 5’ end (left side), but could have been placed towards the 3’ end with an equally good mapping score for the read as shown in figure 31.21.

Since either way of placing the gap is arbitrary, the goal of the mapper is to place the gaps consistently at the same side for all reads.
Figure 31.20: Three A’s in the reference (top) have been replaced by two A’s in the reads (shown in red). The gap is placed towards the 5’ end, but could have been placed towards the 3’ end with an equally good mapping score for the read.

Figure 31.21: Three A’s in the reference (top) have been replaced by two A’s in the reads (shown in red). The gap is placed towards the 3’ end, but could have been placed towards the 5’ end with an equally good mapping score for the read.

Bisulfite read mapping result handling

Click Next lets you choose how the output of the mapping should be reported. There are two independent output options available that can be (de-)activated in both cases:

- **Create report.** This will generate a summary report as described in http://resources.qiagenbioinformatics.com/manuals/clcgenomicsworkbench/current/index.php?manual=Summary_mapping_report.html.

- **Collect un-mapped reads.** This will collect all the reads that could not be mapped to the reference into a sequence list (there will be one list of unmapped reads per sample, and for paired reads, there will be one list for intact pairs and one for single reads where the mate could be mapped).

However, the main output is a reads track:

**Reads track** A reads track is very “lean” (i.e. with respect to memory requirements) since it only contains the reads themselves. Additional information about the reference, consensus sequence or annotations can be added and viewed alongside in the context of a Track List later (by adding, for example, a reference and/or annotation track, respectively). This kind of output is useful when working with tracks in general and especially for resequencing purposes this is recommended.

Note that the tool will output an empty read mapping and report when nothing mapped, and empty unmapped reads if everything mapped.

Figure 31.22 illustrates the view of a typical directional shotgun BS-seq mapping. As with any read mapping view, the colour of the reads follows the usual CLC convention, that is green/red
for forward/reverse reads, and dark/pale blue for paired reads. Independent of this orientation property, each read or read pair has an ‘invisible’ property indicating if it came from the original top (OT), or original bottom (OB) strand. However, if the BS-sequencing protocol is truly 100%-directional, the orientation in the mapping and the OT/OB origin of reads/read pairs will be concordant.

In this figure, blocks of reads from the original top strand are marked with squiggly brackets on the left, while the rest are from the original bottom strand. In a mapping, they can be distinguished by a pattern of highlighted mismatches to reference. OT reads will have mismatches predominantly on ‘T’, due to C->T conversion; OB reads will have a pattern of mismatches on ‘A’ symbols, corresponding to G->A conversion as can be seen on a reverse-complementary strand. When methyl-C occurs in a sample, there will be a match in the reads, instead of an expected mismatch. In this figure, there were two positions where such events occurred, both on the original bottom strand, and both supported by a single read only. ‘G’ symbols in those reads are shown in red boxes. The reverse direction of an arrowhead on a base-level methylation track also reflects the OB-position of a methylation event.

Note also that it appears that there may be a G/T heterozygous SNP (C/A in the OB strand) in the second position. While such occurrences may lead to underestimation of true methylation levels of cytosine alleles in heterozygous SNPs, our current tool does not attempt to compensate for such eventualities.

To understand and interpret BS-sequencing and mapping better, it may be helpful to examine the position (marked with a red asterisk) in between the two detected methylation events. There appears to be an additional A/C heterozygous SNP with C’s in reads from OT strand fully converted to T’s, i.e., showing no evidence of methylation at that heterozygous position.
31.3.3 Call Methylation Levels

The tool takes as input one or more read mappings created by Map Bisulfite Reads to Reference tool (See section 31.3.2). If more than one mapping is used as input, various statistical options to detect differential methylation become available.

The tool will accept a regular mapping as input, but will warn about possibly inconsistent interpretation of results. Mapping done in a 'normal', not bisulfite mode, is likely to result in sub-optimal placement of reads due to a large number of C/T mismatches between bisulfite-converted reads and a reference. Also, this tool will consequently interpret majority of cytosines in a reference as methylated, creating possibly very large and misleading output files. The invisible 'bisulfite' property of a mapping may be erased if the original mapping is manipulated in the workbench with other tools - such as the Merge Read Mappings tool - in which case the warning should be ignored.

After selecting the relevant mapping(s), the wizard offers to set the parameters for base-level methylation calling, as shown in figure 31.23:

![Figure 31.23: Methylation call settings.](image)

- The first three check boxes (Ignore non-specific matches, Ignore duplicate matches, Ignore broken pairs) enable control over whether or not certain reads will be included in base level methylation calling, and subsequent statistical analysis. The recommended option is to have them turned on.
  - Ignore non-specific matches Reads or matches mapped ambiguously will be ignored.
  - Ignore duplicate matches Multiple reads with identical mapping coordinates will be counted once only.
  - Ignore broken pairs Pairs reads mapped as broken pairs will be ignored.

- Read 1 soft clip, Read 2 soft clip: sets a number of bases on a 5'-end of a read that will be ignored in methylation calling. It is common for bisulfite data to have a technical bias in amplification and sequencing, making a small number of bases at the beginning of a read (usually not more than 5) unreliable for calling. Setting a parameter to 0 (default), and inspecting a graph in the report may help determine the specific number for a certain dataset, if a bias is suspected.

- Methylation context group popup menu controls in which context the calls will be made.
- Standard contexts include:
  - **CpG** Detects 5-methylated cytosines in CpG contexts
  - **CHG** Detects 5-methylated cytosines in CHG contexts (H = A/C/T)
  - **CHH** Detects 5-methylated cytosines in CHH contexts

- NOMe-seq contexts [Kelly et al., 2012] include:
  - **GCH** Detects enzymatic methylation in GCH contexts
  - **HCG** Detects endogenous methylation in HCG contexts
  - **GCG** Detects ambiguous methylation in GCG contexts

- **Exhaustive**
  Detects 5-methylated cytosines independently of their nucleotide-context

- **Confirm methylation contexts in reads** checkbox controls if a selected context(s) is present in a read itself, and not just a reference sequence, before a call is made. This is useful if a sample has a variant that can affect a context of a call, so that reads representing a variant allele that breaks a context will be excluded, if the box is checked.

- **Minimum strand-specific coverage** sets a lower limit of coverage for the top, or a bottom strand, to filter out positions with low coverage.

- **Restrict calling to target regions** enables selection of a feature track to limit calling to defined regions. In addition to genes, CDSs and other annotation tracks that can be generated or imported into the workbench, the tool Create RRBS-fragment Track (see section 31.3.4) can be used to generate fragments of pre-selected size predicted for restriction digest of a reference genome with commonly used frequent cutters that target common methylation contexts, such as MspI.

**Statistical tests and thresholds settings**

The next set of parameters depends on experimental setup, and a number of samples in the input, as shown in 31.24.

**Statistical test**

- **Statistic mode** pop-up menu offers the following choices.

- **Fisher exact**: Compares methylation-levels of a case/control sample-pair; multiple case/control samples are merged before pair-wise comparison. Context-specific coverage, and methylated coverage are summed separately for case and control mappings in a window of pre-set size. If more than one case, or control samples are provided, the values within each set are simply added. The contingency table is used to evaluate the hypergeometric cumulative distribution probability for methylated coverage in case sample(s) to be equal or greater than in controls, given the context-specific coverage in a window. Therefore, this test reports statistically significant HYPER-methylation in cases, compared to controls, in a given window. To identify regions that are hypo-methylated compared to controls with this test, simply reverse case and control when specifying the inputs.

- **Chi-squared**: Analyses the inter-individual methylation-level variability across a cohort of samples; no controls are supported. A contingency table is constructed for a window,
Figure 31.24: The statistical tests and thresholds settings.

where each row corresponds to an input sample, with coverage counted for methylated and unmethylated cytosines within strand/context. Expected values for those, given sample coverage in a window, are calculated from aggregate for all samples, and deviation is evaluated with a Chi-squared test. This statistic tells if an input group of samples has methylation heterogeneity between them, in a given window.

- **ANOVA**: Assesses differential methylation by comparing a case-sample group versus a control-sample group; requires at least two case-samples and two control-samples. It tests if variability in methylation levels within each group is less than between groups, in a window of interest.

- **No test**: No test will be performed and only methylation levels will be produced for each input sample; remaining options on that screen will be grayed out.

- **Maximum p-value** sets the limit of probability calculated in a statistical test of choice, at which a window will be accepted as significant, and included in the output.

- **Control samples** menu is used to select bisulfite mappings that are required to serve as controls in either Fisher exact, or Anova statistics.

**Window thresholds**

- **Window length** When no window track was chosen in the previous step for focusing the analysis, examine differential methylation in windows of this fixed size. Defines the size of the window in the genome track within which methylation levels in case and control samples are compared, and statistical significance of difference, if any, is calculated and reported. Windows are evaluated sequentially along the reference.

- **Minimum number of samples** A window will be skipped, if less than this number of samples in a group have coverage at or above the **Minimum strand-specific coverage** in a minimum number of sites, as defined below.
Sample thresholds

- **Minimum high-confidence site-coverage** A site with at least this coverage is considered a high confidence site.
- **Minimum high-confidence site-count** Exclude sample from a current window, if it has fewer than this number high-confidence methylation-sites.
- **Maximum mean site coverage** Exclude sample from current window, if it has a higher mean site coverage. The default "0.0" setting does not filter any.

The tool produces a number of feature tracks and reports. Select the outputs you are interested in during the last wizard step of the tool. The Create track of methylated cytosines option is chosen by default. It will provide a base level methylation track for each read mapping supplied, i.e., case or control (see figure 31.25 for a table view of the track).

Figure 31.25: Output table.

In the table, each row corresponds to a cytosine that conforms to a context (such as ‘CpG’ in this example) and which has non-zero methylated coverage.

The columns of the methylation levels track table view indicate:

- **Chromosome** chromosome in which the methylated cytosine is found
- **Region** position of the mapping where the methylated cytosine is found. Rows with ‘Region’ values that start with ‘complement’ represent methylated Cs in reads that come from the original bottom strand of reference.
- **Name** of the context in which methylation is detected (see tooltip of the wizard for the names and definition of the various contexts available.)
- **Total coverage** total reads coverage of the position. May be calculated after filtering for non-specific, broken, and duplicate reads if these options are enabled.
- **Strand coverage** of the total coverage, how many reads are in the same direction than the strand in which the methylated C is detected (original top, or original bottom)
- **Context coverage** of the strand coverage, how many reads conform to the selected methylation context
- **Methylated coverage** how many reads support evidence of methylation in this position, i.e., retained Cs instead of conversion to Ts
- **Methylation level** "Methylated coverage" divided by "Context coverage"
For each mapping, you can also generate an optional summary report by selecting the **Create methylation reports** option. This report includes statistics of direction of mapping of reads/read pairs, chosen contexts, and useful graphs. The graphs can help detect any bias in called methylation levels that commonly occurs at the start of BS-seq reads due to end-repair of DNA fragments in library preparation. This facilitates setting the correct trimming parameters for Read 1 soft clip, Read 2 soft clip.

Note that positions where no methylation was detected are filtered from the final output and are not reported in the 'Methylation levels' feature track. However they are included in the intermediate calculations for differential methylation detection.

When the statistical test is performed, a feature track is produced. If more than one methylation context is chosen, a separate feature track is produced for each individual context, i.e., for CpG, CHH, etc. The table view of such track for **Fisher exact** test is shown in figure 31.26.

![Figure 31.26: Example of table with statistical test output.](image)

The columns of the differential methylation feature track table indicate:

- **Name** column not used
- **Cytosines** total number of cytosines in the region
- **Case samples** number of samples in the case group
- **Case coverage** sum of "Total coverage" values of the region in the case group
- **Case coverage mean** sum of "Context coverage" in the region divided by the number of covered Cs in context in the region in the case group
- **Case methylated** sum of "Methylated coverage" in the region in the case group
- **Case methylation level** "Case methylated" divided by "Case coverage mean"
- **Control samples** number of samples in the control group
- **Control coverage** sum of "Total coverage" values of the region in the control group
- **Control coverage mean** sum of "Context coverage" in the region divided by the number of covered Cs in context in the region in the control group
- **Control methylated** sum of "Methylated coverage" in the region in the control group
- **Control methylation level** "Case methylated" divided by "Control coverage mean" for the control group
- **p-value** probability of no difference in methylation levels between case and control in the region, given the data and the statistical test applied
For the highlighted window region 833001..834000, the relevant values used in the hypergeometric test are 6 (the number of methylated cytosines in the case sample) out of 7 (total number of cytosines), while the control sample had 11 covered context-conforming cytosines in the region, of which only 2 were methylated. If there are no case/control difference in methylation, the probability (p-value) of such hypermethylation in the case sample is calculated as $9.05 \times 10^{-3}$, below the threshold.

### 31.3.4 Create RRBS-fragment Track

**Create RRBS-fragment Track** can be used to generate fragments of pre-selected size based on the restriction digest of a reference genome with commonly used frequent cutters targeting methylation contexts such as MspI. If such track is provided to the Call Methylation Levels tool, its features are used to calculate statistical tests instead of consecutive windows of pre-set size. The input object is a reference genome of interest, in a track format.

![Create RRBS-fragment track settings](image)

Figure 31.27: *Create RRBS-fragment track settings.*

Figure 31.27 shows the options for generating a track with predicted, and selected features corresponding to restriction digest of the selected genome.

**Restriction enzymes** The enzymes used in reduced-representation bisulfite sequencing can be selected here, with the most common for the CpG islands, MspI, pre-selected by default.

Parameters **Minimum fragment length** and **Maximum fragment length** define the acceptable size range, out of the all possible predicted fragments after full digest of reference DNA, will be included in the output of the tool.

The output of the tool is a feature track.

32.1 Batch Rename ............................................................... 935
32.2 Extract Annotations ....................................................... 940
32.3 Sample reads ............................................................... 942
32.4 Extract Reads ............................................................... 943

32.1 Batch Rename

With the Batch Rename tool it is possible to rename your data in a batch fashion.

To run the batch rename tool:

Toolbox | Utilities ( Utilities ) | Batch Rename ( Batch Rename )

This will open the dialog shown in figure 32.1 where you can select the input data.

![Figure 32.1: Selecting the data you want to rename.]

Click on the button labeled Next to go to the next dialog (see figure 32.2).

Here, one can choose to include or exclude only some of the data that previously selected to work on. For small numbers of data elements, this would not usually be necessary. However, if many data objects were selected at the previous step (to save time when choosing many data elements) you could use the include or exclude functionality at this point so that only certain data elements will be acted on by the batch rename tool.
The **Include** and **Exclude** filters take the text entered into the respective fields and search for matches in the names of the data elements selected in the first wizard step. Thus, you could enter the full names of particular data elements, or just partial names. Any elements where a match is found to the term or terms in the **Include** field will have the batch renaming applied to them. Any elements where a match is found to the term or terms in the **Exclude** field will not have the batch renaming applied to them.

For both filters, if you wish to filter on more than one term at the time, the individual terms must be separated with a comma - and without using a space after the comma. An example is shown in figure 32.3.

In the “Select Target type” step, you can specify at which level you wish to perform the renaming. For a single sequence - as in the example shown in figure 32.4 - this is straightforward because it has just one name, and you would use the **Rename elements** option. But if you have a sequence list, for example, you could choose either to rename the list (using **Rename elements**) or the sequences in the list (using **Rename sequences in sequence lists**). The same goes for alignments (using **Rename sequences in alignments**) and read mappings (using **Rename reads in mappings**). For read mappings, there is also an option to **Rename reference sequence in mappings**.

Click on the button labeled **Next** to open the last dialog (see figure 32.5). For each text field, you can press Shift+F1 (Shift + Fn + F1 on Mac) to get a drop-down list of advanced placeholder options.

At this step you can select between three different renaming options.
Figure 32.4: In this example, as we only have one category represented, the other target type options are disabled.

Figure 32.5: Rename options. At this step you can choose whether you wish to add text to the existing name, replace some of the name, or replace the entire name.

- **Add text to name** This option will add text at the beginning or the end of the existing name, depending on which you choose. Pressing Shift + F1 (Shift + Fn + F1 on Mac) will enable a list of different renaming options as shown in figure ???. The different options are presented as e.g. #BR-E#, which means "Batch Rename - Enumeration" = the current name is kept, and if "At the end" was selected, consecutive numbers will be added directly after the existing name (without introducing a space between the existing name and the new addition). Please note, that the numbering will follow the order of which the data were selected in the first dialog under "Select Elements".

- **Replace part of name** This is an advanced function that allows to replace e.g. data with completely different names in one go with a new name. This is shown in figure 32.6.

The option to replace part of a name is based on regular expressions. Regular expressions allow you to describe text in a flexible manner. For more details, please see: http://docs.oracle.com/javase/tutorial/essential/regex/.

By clicking in either the From: or To: box and pressing the Shift and F1 keys at the same time (Shift + Fn + F1 on Mac), you will see a drop down list of renaming possibilities. The options listed for the From: field are some of the most commonly used regular expressions. Other standard regular expressions are also admissible in this field. **Note!** Please ensure
that if you choose any of these options, or other regular expressions, that you check in the box labeled "Interpret From as Java Regular Expressions". If you do not check this box, then the characters you enter in the From box will be interpreted literally. For example, a full stop or period (.) is interpreted as that character (.) when this box is not checked, but is interpreted as meaning any single character when the box is checked.

An example: if you enter "From:" "Regular Expression: Range ([A-Z]) "To:" "Enumeration (#BR-E#)", titles containing any (capital) letters will be renamed to consecutive numbers. A more advanced example where the sequences shown in the images earlier in this manual are used is shown in figure 32.7. The sequence names contain both a capital letter, small letters and a number. In the first, the number is kept and a date is added in front of the number.

As this can be a bit difficult to grasp, we will look at three more examples. We will use the name **1N R1_0001** in the two first examples:

1. First we want to keep only the first 4 none-whitespace characters of the name(s). To do this write the following in the "From" and "To" fields shown in figure 32.7:

   **From:** `(^\S{4}).*`
**Nomenclature:** ^: start of the line, \$: none-whitespace characters, {4}: 4 characters, .*: everything after the pattern

**To:** $1

**Nomenclature:** $1: the first group in the "From" field

The result of this is that 1NR1 is kept, whereas the space between "N" and "R1" and _0001 have been discarded.

2. If we would like to keep only the last 4 characters of the name(s):

**From:** (.*) (.{4}$)

**Nomenclature:** (.*): the first group, (.{4}$): any 4 character at the end of the line as the second group

**To:** $2

**Nomenclature:** $2: the second group in the "From" field

The result of this is that 0001 is kept, whereas 1N R1_ has been discarded.

3. Now we would like to replace the first letter followed by 9 numbers in the name "p140101034_1R_AMR" with the parent folder name, which in this case is "AmericanSamples".

**From:** ([A-Z]\d{9})(.*)

**Nomenclature:** [A-Z]: any character (as long as they are part of [A-Z][a-z], the CLC software do not differentiate between upper/lower case), \d{9}: any 9 digit numbers, (.*): the second group of the name (anything after the "([A-Z]\d{9})" pattern ).

**To:** #BR-F#$2

**Nomenclature:** $2: the second group in the "From" field.

The result of this is that we have replaced "p140101034" with "AmericanSamples" and as a result have changed the name from p140101034_1R_AMR to AmericanSamples_1R_AMR.

4. If we want to extract and use the text "sample-code" for the new name from the following "1234_sample-code_5678" with Java Regular Expressions:

**From:** (^[^_]+)_(^[^_]+)_(.*)

**Nomenclature:** ^[^_]+: Starting from the beginning and match anything before the first underscore,

[^_]+: will match anything and stop before the second underscore.

After the second underscore, the match will include the rest of the name.

**To:** $2

**Nomenclature:** $2: includes the match from the second group, which is flanked between the first and the second underscore symbols of the name.

- **Replace full name** Allows replacement of the entire name with the name that is either typed directly into the text field, or with options that can be selected when pressing Shift + F1 (Shift + Fn + F1 on Mac). Figure 32.8 shows an example where a combination of "Shift +F1" (Shift + Fn + F1 on Mac) options (#BR-D# and #BR-E#) are used together with user-defined text (RNA-Seq).

Click **Finish** to start renaming. Please note that the **rename cannot be undone** and that it does not show up in the **History** (🗑️).
CHAPTER 32. UTILITY TOOLS

Figure 32.8: The entire name is removed from the primer names and is replaced with "Today’s date" (BR-D#), the user-defined text: RNA-Seq, and the addition of consecutive numbers (BR-E#). In this case we have inserted a space between the date, the user-defined text and the added number. If commas were inserted instead, the commas would be part of the new name as everything that is typed into the text field will be used in the new name when renaming the entire name.

32.2 Extract Annotations

The **Extract annotations** tool makes it very easy to extract parts of a sequence (or several sequences) based on its annotations. In just a few steps, it becomes possible to:

- extract all tRNA genes from a genome.
- automatically add flanking regions to the annotated sequences.
- search for specific words in all available annotations.
- extract nucleotide sequences of differentially expressed genes or transcripts when using RNA-seq statistical comparisons as input.

The output is a sequence list that contains sequences carrying the annotation specified (including the flanking regions, if this option was selected).

To extract annotations from a sequence, go to:

**Toolbox | Utility Tools | Extract Annotations**

This opens the dialog shown in figure 32.9 where you can select one or more annotated sequences, or annotation tracks, or variant tracks, or statistical comparisons. Click **Next**.

Figure 32.9: Select one or more annotated sequences, annotations, variant tracks or (in this figure) statistical comparisons.

If you selected tracks as input, the next step will ask for a reference sequence track to use for extracting the annotations, or which annotations to use if an annotated sequence was selected.
as input (figure 32.10).

Figure 32.10: Adjusting parameters for extract annotations.

- **Search terms.** All annotations and attached information for each annotation will be searched for the entered term. It can be used to make general searches for search terms such as "Gene" or "Exon", or it can be used to make more specific searches. For example, if you have a gene annotation called "MLH1" and another called "MLH3", you can extract both annotations by entering "MLH" in the search term field. If you wish to enter more specific search terms, separate them with commas: "MLH1, Human" will find annotations including both "MLH1" and "Human".

- **Annotation types** If only certain types of annotations should be extracted, this can be specified here.

The sequence of interest can be extracted with flanking sequences:

- **Flanking upstream residues.** The output will include this number of extra residues at the 5’ end of the annotation.

- **Flanking downstream residues.** The output will include this number of extra residues at the 3’ end of the annotation.

The sequences that are created can be named after the annotation name, type etc:

- **Include annotation name.** This will use the name of the annotation in the name of the extracted sequence.

- **Include annotation type.** This corresponds to the type chosen above and will put this information in the name of the resulting sequences. This is useful information if you have chosen to extract "All" types of annotations.
• **Include annotation region.** The region covered by the annotation on the original sequence (i.e. not including flanking regions) will be included in the name.

• **Include sequence/track name.** If you have selected more than one sequence as input, this option enables you to discern the origin of the resulting sequences in the list by putting the name of the original sequence into the name of the resulting sequences.

Click **Finish** to start the tool.

### 32.3 Sample reads

The **Sample Reads** tool is very useful for reducing the size of data sets. It allows the user to reduce the number of reads in a sequence list to an absolute number of reads, or a pre-defined percentage of the original list.

A reduced sequence list can be relevant when editing contigs with a high coverage, as an excessive amount of reads can be overly resource-demanding and can hinder read mapping editor functions. Sampling reads, and subsequently mapping the sampled reads to contigs with the Map Reads to Contig tool can maintain the speed of many edit operations in the contig aligner without any loss of important information. Similarly, in the case of de novo assembly, very high coverage in a location will increase the probability this location is seen as a sequencing error. You can thus use the Sample Reads tool to reduce coverage to a maximum average coverage of 100x using the following calculation:

1. Multiply the estimated size of the genome you intend to assemble by 100. This value will be the total number of bases you should use as input for assembly.

2. Divide the total input bases the average length of your sequencing reads.

3. Use this number as input for the number of reads to obtain as output from the Sample Reads tool.

To learn more about the Map Reads to Contig tool and the De Novo Assembly tool, see chapter 30.

To run the **Sample Reads** tool: **Toolbox | Utility Tools | Sample reads**

This opens the dialog shown in figure 32.11. Select the relevant reads and click **Next**.

![Figure 32.11: Select the reads.](image)

This leads to the **Sample size parameters** step shown in figure 32.12.
In the Sample size parameters it is possible to sample down to either an absolute number of reads, or a sample percentage of the original file, with sample percentage defining the percentage of the sub-sample paired reads (for single end reads) and pairs of reads (for paired reads).

It is also possible to choose between a Reproducible or Random output. The Reproducible option will always returns the same sample (i.e., containing the same reads) for a given sample size or percentage; the Random option returns a different sample each time the tool is run.

After the Result handling step, click Finish.

32.4 Extract Reads

This tool can be used to extract subsets of reads based on annotations. When extracting reads with a specific annotation, the annotation will function as a tag pulling out all the reads with the overlapping annotation (or, when handling paired read data, all the pairs of reads). To launch the tool, go to:

Toolbox | Utility Tools | Extract Reads

Read mapping tracks can be used as input (figure 32.13).

The next step offers the possibility to select one or more annotated track(s) to be used for pulling out reads and specify which reads to include (figure 32.14). Note that it is also possible to select here a RNA-seq statistical comparison.

With the options "Only include reads within the intervals", it is possible to select whether only reads within the intervals should be extracted, or whether reads continuing outside the annotated
Figure 32.14: Select the track(s) containing the annotation(s) of interest. Multiple tracks can be selected at the same time.

region should be extracted. The difference between the options can be seen in figure 32.15.

![Output from the Extract Reads tool. Top: The read mapping used as input. Middle: Output when "Only include reads within intervals" has been deselected. Bottom: Output when "Only include reads within intervals" has been selected.](image)

In the next dialog, specify which reads should be included in the output. They are all selected by default as seen in figure 32.16.

**Match specificity**
- Include specific matches Reads that only are mapped to one position.
- Include non-specific matches Reads that have multiple equally good alignments to the reference. These reads are colored yellow per default.

**Alignment quality**
- Include perfectly aligned reads Reads where the full read is perfectly aligned to the reference sequence (or consensus sequence for de novo assemblies). Note that at the end of the contig, reads may extend beyond the contig (this is not visible unless you make a selection on the read and observe the position numbering in the status
bar). Such reads are not considered perfectly aligned reads because they don’t align in their entire length.

- Include reads with less than perfect alignment Reads with mismatches, insertions or deletions, or with unaligned nucleotides at the ends (the faded part of a read).

**Spliced status**

- Include spliced reads Reads that are across an intron.
- Include non spliced reads Reads that are not across an intron.

**Paired status**

- Include intact paired reads When paired reads are placed within the paired distance specified, they will fall into this category. Per default, these reads are colored in blue.
- Include reads from broken pairs When a pair is broken, either because only one read in the pair matches, or because the distance or relative orientation is wrong, the reads are placed and colored as single reads, but you can still extract them by checking this box.
- Include single reads This will include reads that are marked as single reads (as opposed to paired reads). Note that paired reads that have been broken during assembly are not included in this category. Single reads that come from trimming paired sequence lists are included in this category.

In the last step, you can choose to output a reads track or sequence list(s).

A folder with the name Legacy Tools (Legacy Tools) is found at the bottom of the toolbox. The tools found in this folder are tools that have been used in older versions of the workbench but are now deprecated. These tools will be retired in a future version of the workbench.

If you are using tools in the Legacy section of the Toolbox in workflows, then we recommend redesigning those workflows to exclude these tools. In the cases where a tool has been deprecated and a new tool introduced to take its place, please try updating the workflows to include the new tool.

If you have concerns about the retirement of particular tools currently appearing in the Legacy section of the Toolbox, please contact QIAGEN Bioinformatics Support team at ts-bioinformatics@qiagen.com.

33.1 Compare Sample Variant Tracks

The Compare Sample Variant Tracks tool allows you to compare two samples and filter away the variants that are either identical or different. If you want to focus on variants that are found in both samples you should choose the option "Keep variants that are the same". These variants will be the same no matter which sample was selected as the first input (the "variant track") or the second input (the "comparison track", which also is a variant track).
If you want to focus on variants that differ between the two tracks, the order in which the two samples are selected matters, as the tool will not combine the variants in the two tracks, but will filter out one. This is illustrated in figure 33.1.

![Figure 33.1: The figure illustrates the different types of output you will get depending on which choices you have made in the wizard steps.](image)

To run the tool:

**Legacy Tools | Compare Sample Variant Tracks**

In the first step of the dialog, you select the variant track that should be taken as input. Clicking **Next** shows the dialog in figure 33.2.

![Figure 33.2: Comparing against variants in "Variants Proband". A tooltip describes the difference between keeping variants that are the same or the ones that are different.](image)

At the top, select the comparison track. Below, you can choose whether the result should be the variants from the input that match the comparison track, or whether it should be the variants that are different from the variant track. The match criterion here is an exact match on the position and allele sequence.
33.2 Download Reference Genome Data

The CLC Genomics Workbench offers an easy way of retrieving popular reference data sources such as genes, variant annotations and genome sequences as tracks. The data itself is not provided or hosted by QIAGEN. The workbench only provides an easy way to retrieve data that should otherwise have been downloaded and imported:

Legacy Tools | Download Reference Genome Data

This opens the dialog shown in figure 33.3:

![Download Reference Genome Data Dialog](image)

Select the organism of interest and click Next. The list of organisms is dynamically updated by QIAGEN independently of Workbench versions, so you will always see the most recent list of organisms.

The list just shows a selection of some of the popular organisms – if you do not find what you are looking for, there is always the possibility to download and import the data as well.

Once you have clicked Next, you will be asked whether you wish to download the genome sequence or whether you already have it available as shown in figure 33.4:

If you do not already have an existing sequence imported into the CLC Genomics Workbench, it will be downloaded automatically from Ensembl. If you already have a reference sequence, it has to match the genome definition built into the download tool. This means that the name and length of the chromosomes in your reference sequence have to match the genome definition of the tool.

Clicking Next allows you to select which types of annotation data you wish to download as shown in figure 33.5:

This step is different from organism to organism and depends on the data sources that QIAGEN has included for download. In the example in figure 33.5 showing hg19 build of the human genome, a lot of variant data is available from e.g. dbSNP. Please note that for human data, a
difference between the UCSC genome build and Ensembl/NCBI exists, which means that variants downloaded from UCSC will not be annotated on the mitochondrial genome when using this download tool (see http://genome.ucsc.edu/cgi-bin/hgGateway?db=hg19).

Both the data provider and the size of the data is listed in the dialog, and at the bottom you can see the size of all the selected downloads. Please note that the file size displayed in the setup window for the Download Genomes tool refers to the size of the compressed text files, which the tool is retrieving from the provider’s depository. The size of the track objects will be, after decompression and conversion from text to the .clc track format, notably larger.

All data downloaded with this tool will be tracks (either sequence tracks or various kinds of annotation tracks). The Ensemble human gene annotation download will produce various tracks describing the chromosomal positions of features such as exons, genes, untranslated region (UTRs), transcripts, selenocysteines, coding sequences (CDSs) and mRNAs.
33.3 Identify Differentially Expressed Gene Groups and Pathways

This tool can be used to investigate candidate differentially expressed genes for a common functional role. For example if you would like to compare different cancer patients to check whether e.g. the same pathways are affected in different individuals, you can use this tool.

For this, you need a GO association file, which includes gene names and associated Gene Ontology terms. A GO association file with the top-level GO terms annotated (GO slim) is provided with the CLC Genomics Workbench and can be downloaded using the Data Management function found in the top right corner of the Workbench (see section 8.2).

To run the analysis go to the toolbox:

Legacy tools | Identify Differentially Expressed Gene Groups and Pathways

When you run the Identify Differentially Expressed Gene Groups and Pathways analysis, you first have to select the expression comparison track you wish to annotate with the GO term enrichment analysis. Expression comparison tracks can be created e.g. by the create fold change track tool (see section 33.7).

After clicking Next, you have to specify the annotation association file, a gene track, and finally which ontology (cellular component, biological process or molecular function) you would like to test for (see figure 33.6).

![Figure 33.6: Select gene track, GO annotation table, and ontology.](image)

Next, the Workbench tries to match gene names from the expression comparison track with the gene names in the GO association file. Please be aware that the same gene name definition should be used in both files.

Based on this, the Workbench finds GO terms that are over-represented in the list. A hypergeometric test is used to identify over-represented GO terms by testing whether some of the GO terms are over-represented in a given gene set, compared to a randomly selected set of genes.

The result is a table with GO terms and the calculated p-value for the differentially expressed genes, and a new expression comparison track with annotated GO terms and the corresponding p-value (see figure 33.7). The p-value is the probability of obtaining a test statistic at least as extreme as the one that was actually observed, or in other words how significant (trustworthy) a result is. In case of a small p-value the probability of achieving the same result by chance with the same test statistic is very small.
33.4 Merge Overlapping Pairs

Some paired end library preparation methods using relatively short fragment size will generate data with overlapping pairs. This type of data can be handled as standard paired-end data in the CLC Genomics Workbench, and it will work perfectly fine (see details for variant detection in section 26.1.3).

However, in some situations it can be useful to merge the overlapping pair into one sequence read instead. The benefit is that you get longer reads, and that the quality improves (normally the quality drops towards the end of a read, and by overlapping the ends of two reads, the consensus read now reflects two read ends instead of just one).

In the CLC Genomics Workbench, there is a tool for merging overlapping reads, which are in forward-reverse orientation:

**Toolbox | Legacy Tools | Merge Overlapping Pairs**

Select one or more sequence lists with paired end sequencing reads as input.

Please note that read pairs have to be in forward-reverse orientation. Please also note that after merging the merged reads will always be in the forward orientation. As an aside, length trimming of reads can be done before or after merging, however the merged read’s 3’ is the 5’ of the reverse read, so that trimming the original reads using the Remove 5’ terminal nucleotides option corresponds to trimming the merged reads using both the Remove 5’ terminal nucleotides option and the Remove 3’ terminal nucleotides option.

Clicking **Next** allows you to set parameters as displayed in figure 33.8.

In order to understand how these parameters should be set, an explanation of the merging algorithm is needed: Because the fragment size is not an exact number of base pairs and is different from fragment to fragment, an alignment of the two reads has to be performed. If the alignment is good and long enough, the reads will be merged. Good enough in this context means that the alignment has to satisfy some user-specified score criteria (details below). Because of sequencing errors that typically are more abundant towards the end of the read, the alignment is not expected always to be perfect, and the user can decide how many errors are acceptable. Long enough in this context means that the overlap between the reads has to be non-coincidental. Merging two reads that do not really overlap, leads to errors in the downstream analysis, thus it is very important to make sure that the overlap is big enough. If only a few bases overlap was
required, some read pairs will match by chance, so this has to be avoided.

The following parameters are used to define what is good enough and long enough:

- **Mismatch cost** The alignment awards one point for a match, and the mismatch cost is set by this parameter. The default value is 2.

- **Gap cost** This is the cost for introducing an insertion or deletion in the alignment. The default value is 3.

- **Max unaligned end mismatches** The alignment is local, which means that a number of bases can be left unaligned. If the quality of the reads is dropping to be very poor towards the end of the read, and the expected overlap is long enough, it makes sense to allow some unaligned bases at the end. However, this should be used with great care which is why the default value is 0. As explained above, a wrong decision to merge the reads leads to errors in the downstream analysis, so it is better to be conservative and accept fewer merged reads in the result.

- **Minimum score** This is the minimum score of an alignment to be accepted for merging. The default value is 10. As an example: with default settings, this means that an overlap of 13 bases with one mismatch will be accepted (12 matches minus 2 for a mismatch).

Please note that even with the alignment scores above the minimum score specified in the tool setup, the paired reads also need to have the number of end mismatches below the "Maximum unaligned end mismatches" value specified in the tool setup to be qualified for merging.

After clicking **Next** you can select whether a report should be generated as part of the output. The main result will be two sequence lists for each list in the input: one containing the merged reads (marked as single end reads), and one containing the reads that could not be merged (still marked as paired data). Since the CLC Genomics Workbench handles a mix of paired and unpaired data, both of these sequence lists can be used in the further analysis. However, please note that low quality can be one of the reasons why a pair cannot be merged. Hence, the list of reads that could not be paired is more likely to contain more reads with errors than the one with the merged reads.

Quality scores come into play in two different ways when merging overlapping pairs.

*First*, if there is a conflict between the reads in a pair (i.e. a mismatch or gap in the alignment), quality scores are used to determine which base the merged read should have at a given position. The base with the highest quality score will be the one used. In the case of gaps, the average
of the quality scores of the two surrounding bases will be used. In the case that two conflicting bases have the same quality or both reads have no quality scores, an [IUPAC ambiguity code](see the appendix section G) representing these bases will be inserted.

Second, the quality scores of the merged read reflect the quality scores of the input reads.

We assume independence of errors in calculating the new quality score for a merged position and carry out the following calculations:

- When the two reads agree at a position, the two quality scores are summed to form the quality score of the base in the new read. The score is capped at the maximum value on the quality score scale which is 64. Phred scores are log scores, so their sums represent the multiplication of the original error probabilities.

- If the two bases disagree at a position, the quality score of the base in the new read is determined by subtracting the lowest score from the highest score of the input reads. Similar to the addition of scores when bases are the same, this adjusts the error probability to reflect a decreased certainty that the base reported at that position is correct.

Thus, if two bases at a given position of an overlapping region are different, and each of those bases was originally given a high phred score, the score assigned to the merged base will be very low. This reflects the fact that the base at this position is unreliable.

If a base at a given position in one read of an overlapping region has a very low quality score and the base at that position in the other read has a high score, it is likely that the base with the high quality score is correct. The adjusted quality score for this position in the merged read would reflect that there is less certainty in the base at that position than before. However, such a position would still be assigned quite a high quality, as the base call is still likely to be correct.

Figure 33.9 shows an example of the report generated when merging overlapping pairs.

It contains three sections:

- A summary showing the numbers and percentages of reads that have been merged.
- A plot of the alignment scores. This can be used to guide the choice of minimum alignment score as explained in section 33.4.
- A plot of read lengths. This shows the distribution of read lengths for the pairs that have been merged:
  - The length of the overlap.
  - The length of the merged read.
  - The combined length of the two reads in the pair before merging.

### 33.5 Add Information from Overlapping Genes

This will create a copy of the track used as input and add information from overlapping genes and mRNA tracks as well as annotations from GeneCards. To run the Add information from overlapping genes tool, go to the toolbox:

Toolbox | Legacy Tools | Add Information from Overlapping Genes
First, select the track you wish to annotate and click **Next**. You can choose any kind of variant or annotation track as input. Next, select the a gene track and a mRNA track for overlap comparison (figure 33.10).

You can find the gene and mRNA tracks in the CLC References folder (figure 33.11).

The result of this tool is a new track showing all the variants that now have been annotated with the information about genes and mRNA as well as annotations from GeneCards that overlap with the identified variants. The requirement for being registered as an overlap is that parts of the annotations are overlapping, regardless of the strandedness of the annotations (note that this makes it unsuitable for comparing e.g. two gene tracks but great for annotating variants with overlapping genes or regulatory regions). The added information can be visualized in two ways; 1) In the track tooltips when mousing over the individual variants or 2) in the table view where you can see that new columns describing the added gene and mRNA tracks have been added to the table. The table view can be accessed by clicking on the table icon (囲) in the lower part of the **View Area**.

Figure 33.9: *Report of overlapping pairs.*
CHAPTER 33. LEGACY TOOLS

33.6 Import Roche 454

To open the Roche 454 Import tool, go to:

Legacy Tools | Roche 454

Choosing the Roche 454 import will open the dialog shown in figure 33.12.

We support import of two kinds of data from 454 GS FLX systems:

- Flowgram files (.sff) which contain both sequence data and quality scores amongst others. However, the flowgram information is currently not used by CLC Genomics Workbench. There is an extra option to make use of clipping information (this will remove parts of the sequence as specified in the .sff file).

- Fasta/qual files:
  - 454 FASTA files (.fna) which contain the sequence data.
Figure 33.12: Importing data from Roche 454.

- Quality files (.qual) which contain the quality scores.
- Compressed data in gzip format is also supported (.gz).

The General options to the left are:

- **Paired reads.** The paired protocol for 454 entails that the forward and reverse reads are separated by a linker sequence. During import of paired data, the linker sequence is removed and the forward and reverse reads are separated and put into the same sequence list (their status as forward and reverse reads is preserved). You can change the linker sequence in the Preferences (in the Edit menu) under Data. Since the linker for the FLX and Titanium versions are different, you can choose the appropriate protocol during import, and in the preferences you can supply a linker for both platforms (see figure 33.13. Note that since the FLX linker is palindromic, it will only be searched on the plus strand, whereas the Titanium linker will be found on both strands. Some of the sequences may not have the linker in the middle of the sequence, and in that case the partial linker sequence is still removed, and the single read is put into a separate sequence list. Thus when you import 454 paired data, you may end up with two sequence lists: one for paired reads and one for single reads. Note that for de novo assembly projects, only the paired list should be used since the single reads list may contain reads where there is still a linker sequence present but only partially due to sequencing errors. Read more about handling paired data in section 6.3.7.

- **Discard read names.** For high-throughput sequencing data, the naming of the individual reads is often irrelevant given the huge amount of reads. This option allows you to discard this option to save disk space.

- **Discard quality scores.** Quality scores are visualized in the mapping view and they are used for SNP detection. If this is not relevant for your work, you can choose to Discard quality scores. One of the benefits from discarding quality scores is that you will gain a lot in terms of reduced disk space usage and memory consumption. If you have selected the fna/qual option and choose to discard quality scores, you do not need to select a .qual file.
**Figure 33.13: Specifying linkers for 454 import.**

**Note!** During import, partial adapter sequences are removed (TCAG and ATGC), and if the full sequencing adapters GCCCTGCCAGCCCGCTCAG, GCCTCCCCTCCCGCCATCAG or their reverse complements are found, they are also removed (including tailing Ns). If you do not wish to remove the adapter sequences (e.g. if they have already been removed by other software), please uncheck the **Remove adapter sequence** option.

Click **Next** to adjust how to handle the results (see section 9.2). We recommend choosing **Save** in order to save the results directly to a folder, since you probably want to save anyway before proceeding with your analysis. There is an option to put the import data into a separate folder. This can be handy for better organizing subsequent analysis results and for batching (see section 9.3).

### 33.7 Create Fold Change Track

The **Create Fold Change Track** tool can be used to compare RNA expression levels in two samples (e.g., matched tumor and normal samples).

After RNA-seq analysis, the resulting expression tracks can be compared using the **Create Fold Change Track** tool. For each gene or transcript, this tool will compute the ratio of the expression value in the case track to the expression value of the same gene in the control track. The tool enables filtering on the basis of fold-changes as well as expression values. This can give a quick first indication of possible differentially expressed genes or transcripts between two RNA-seq samples. For a more detailed and statistically robust analysis, we recommend running a Statistical Analysis tool in the **CLC Genomics Workbench**.

The tool for creating a fold-change track can be found here:

**Toolbox | Legacy Tools | Create Fold Change Track ( )**

After starting the Create Fold Change Track tool, select the expression track corresponding to the case sample in the input dialog, as shown in figure **33.14**, and click on the button labeled **Next**.
You are now presented with the wizard step shown in figure 33.15 where you can set the following input parameters:

- **Control expression track** At the top of the wizard, a control expression track must be chosen. The control expression track will be used as the reference in creating the fold-change track.

- **Log fold change value** In the middle of the wizard, the parameters relating to the reported fold-change values can be specified.
  - Scale Determines on what scale the fold-changes should be reported and interpreted:
    - **Raw** The fold-changes will be reported as a direct ratio: \( \frac{\text{case expression}}{\text{control expression}} \)
    - **Log-2** The fold-changes will be reported as log-2 values: \( \log_2 \left( \frac{\text{case expression}}{\text{control expression}} \right) \)
    - **Log-10** The fold-changes will be reported as log-10 values: \( \log_{10} \left( \frac{\text{case expression}}{\text{control expression}} \right) \)
    - **Natural logarithm** The fold-changes will be reported as log-e values: \( \log \left( \frac{\text{case expression}}{\text{control expression}} \right) \)
– **Fold-change cutoff** Enables filtering in the results based on fold-changes. Note that the value entered into the fold-change cutoff field will be interpreted according to the scale specified in the scale parameter. For example, if the expression level of a gene is 100 in the case sample and 200 in a control sample, then a cutoff of 1.5 with the scale parameter set to Raw will not result in the gene being filtered on the basis of fold-changes, and the gene will appear in the final results. However, if the scale parameter is set to Log10, the gene will be filtered and will not appear in the final results. To include all genes or transcripts in the output without filtering on the basis of fold-changes, enter 0 in this field (this will work for any value specified for the scale parameter).

• **Noise reduction filter** A second level of filtering is possible based on absolute expression levels. The rationale behind this filtering is that seemingly very large fold-changes can occur by chance if the expression levels are very low in both samples, creating a false-positive noise in the resulting fold-change track. Therefore, it is desirable to require a certain level of expression for a gene in at least one of the samples. This can be specified using the Ignore features with maximum expression level below parameter.

– **Ignore features with maximum expression level below** The value entered in this field corresponds to the minimum expression level required in either the case or the control track, in order for the gene or transcript to appear in the results. If the expression level does not exceed this value in either the case or the control sample, the gene or transcript will be filtered out from the final results. Entering a value of 0 for this parameter will not filter any genes or transcripts based on absolute expression levels.

When finished with setting the parameters, click Next.

The Create Fold Change Track tool will produce an annotation track, including the genes or transcripts that were not filtered out based on the filtering criteria. Each feature in this track is annotated with the following information:

• **Fold-change** Represents the fold-change according to the specified scale. A positive value indicates that the expression level was higher in the case. A negative value indicates that the expression level was higher in the control. If Raw was specified for the scale parameter, a value of 0 represents no difference. If a logarithm-based value was specified for the scale parameter, a value of 1 represents no difference.

• **Difference** Represents the difference in expressions. A positive value indicates that the expression level was higher in the case. A negative value indicates the expression level was higher in the control.

• **Maximum expression** Represents the larger of the expression values observed in the case and the control samples.

• **Expression (case)** Gives the expression value in the case sample

• **Expression (control)** Gives the expression value in the control sample

As is the case with all annotation tracks in the CLC Genomics Workbench, it is possible to sort and filter the results based on any of the above values, and to create track lists for further analysis of the results.
33.8 Add Fold Changes

With this tool you can add the expression fold changes to your variants. You will create a copy of the input variant track and add the gene name and expression fold changes to this track. When you have added the expression fold changes to the variant track, they can be seen in the tooltip when you zoom all the way in on the individual variants or in the table view.

To add fold changes, go to the toolbox:

Toolbox | Legacy tools | Add Fold Changes

If you are connected to a server, you will first be asked where you would like to run the analysis. Next, you will be asked to select the variant track that you would like to add fold changes to (figure 33.16). To select the variant track, double-click on the file name or click once on the file and then on the arrow pointing to the right side in the middle of the wizard. Click on the button labeled Next.

![Figure 33.16: Select the variant track.](image)

In the next step you can choose the fold change track (see figure 33.17).

![Figure 33.17: Select the fold change track.](image)

Click on the button labeled Next, choose to save the results and click Finish.

The generated output is a variant track. If you open the variant track in table view by clicking on the table icon in the lower left corner of the View Area, you can see in the Side Panel under Table Settings that "Fold change" and "Gene" have been added to the list. If you would like to
look into the numbers behind the fold changes, you can see the expression values in the original fold change file that was used as input in the "Add Fold Changes" analysis.

33.9 Create Track from Experiment

The Create Track from Experiment tool in the CLC Genomics Workbench enabled the conversion of experiments to tracks.

You can find the Create Track from Experiment tool here:

Toolbox | Legacy Tools | Create Track from Experiment

After you start the tool, you are presented with a wizard where you can choose the experiment that you would like to create a track of. The Create Track from Experiment tool can be run on experiments with associated genomic information, such as those created using expression tracks from the RNA-Seq Analysis tool.

In the case where the experiment has associated genomic information, the Create Track from Experiment tool will automatically infer these and the wizard will jump directly to the filtering step, as shown in figure 33.19.

In the case where the experiment does not have associated genomic information, you will first need to specify how the genomic information should be obtained in the parameters step of the Create Track from Experiment tool (figure 33.18).

Figure 33.18: The "Input parameters" step in the Create Track from Experiment tool.

In the Input parameters step, you must specify the following parameters:

- **Reference genome.** The chosen genome will be used as the reference genome for the resulting track.
- **Chromosome column.** The column containing the chromosome names must be chosen from the drop-down menu.
- **Chromosomal region start.** The column containing the start of the genomic regions must be chosen from the drop-down menu.
- **Chromosomal region end.** The column containing the end of the genomic regions must be chosen from the drop-down menu.

**Note!** The drop-down menus will only contain the columns that potentially represent the information required by the given parameter. If the experiment does not contain any columns that
potentially represent the required genomic information, the drop-down menus may appear empty. In this case, it is not possible to convert the given experiment to a track.

In the filtering step (figure 33.19), you have the following options:

- **Filter based on statistical analysis results** This allows to filter which annotations are transferred to the track on the basis of the statistical analysis. To enable filtering, check the **Filter based on statistical analysis results** checkbox. The filtering option is only available if a statistical analysis has previously been carried out on the experiment, and the drop-down menu will only contain the statistical analyses that are present on the experiment.

- **Statistical analysis** Allows you to choose statistical analysis from the drop-down list. The selection of available statistical analyses depends on which tests have been used when you set up the experiment that you are about to convert to track format.

- **Type of p-value** This drop-down menu allows you to select between raw and corrected p-values. Only the types of p-values available for the given statistical analysis will be present in the drop-down menu.

- **Maximum p-value** In this input field, you can enter the maximum allowed p-value, as a number between 0 and 1. If you do not want any filtering based on p-value, enter 1.

- **Minimum fold-change value** You can also specify the minimum allowed fold-change value as a number greater than zero. If you do not want any filtering based on fold-change, enter 0.

You can then select in the drop-down menu which analysis you want to use for filtering.

The fold change values are stored as different columns in the experiment, depending on the statistical analysis performed. The Create Track from Experiment tool will automatically use the fold-change column appropriate for the different statistical analyses:

- **Kal’s Z-test** (see section 29.5.2): Proportions fold change.

- **Baggerley’s test** (see section 29.5.2): Weighted proportions fold change.

- **T-test** (see section 29.5.3): Fold change.
• ANOVA (see section 29.5.3): Max fold change.

• Empirical analysis of DGE (see section 29.5.1): Fold change.

The resulting track will contain only differentially expressed genes whose p-value is lower than the specified threshold and whose fold-enrichment is above the specified threshold.

If the chosen statistical analysis was performed on several pairs of groups, there will be an output track for each tested pair of groups. For example, if the same statistical analysis has been carried out on ‘group 1 vs. group 2’ and ‘group 1 vs. group 3’, then the output will contain two tracks, where one is filtered according to the ‘group 1 vs. group 2’ analysis results and the other one is filtered according to the ‘group 1 vs. group 3’ analysis results.

When running the Create Track from Experiment tool as part of a workflow, there are a few differences in how the parameters are set (see figure 33.20).

• The Source of genomic information parameter determines the behavior of the algorithm if the incoming experiment is not coupled to a genome. If the value of this parameter is set to Require genomic information in experiment, then the algorithm will expect the incoming experiment to be coupled to a genome, and will fail with an error alerting the user in case the experiment does not fulfill this criterion. If the value of the parameter is set to Automatic: use genomic information if available, then the algorithm will still use the genomic information in a genome-coupled experiment. But if this information is not available, the algorithm will attempt to use the information specified by the user in the workflow parameters. Note: If the incoming experiment is coupled to a genome (as will usually be the case), the value of this parameter makes no difference.

• In a workflow setting, the column titles for the chromosome, region end and region start fields can be specified as texts. These fields may be left empty, if the incoming experiment contains the genomic information. If filling out these fields, note that the format for this text is very strict, and must exactly match the text appearing in the drop-down menu when running the tool from the toolbox. For example, if ‘Chromosome’ is a sample-specific column, for a sample called ‘Liver (GE)’ in the ‘liver’ group in the experiment, then the column name text will be: ‘liver - Liver (GE) - Chromosome’.

![Figure 33.20: Setting the parameters for the Create Track from Experiment tool in a workflow.](image)
The Create Track from Experiment tool will produce a track or several tracks, if filtering based on analysis results was chosen. The track(s) will contain the following annotations:

- All experiment-specific columns from the experiment
- All user-defined annotations added to the experiment
- All analysis-specific columns from the experiment
- All group-specific columns from the experiment
- Those of the following sample-specific columns when present in the experiment (for each sample): Expression values, Total exon reads, and RPKM.

Two different view options exist: the Track List and the Table View. When opening the annotated output result, the default view is the Track List. It is possible to open both views in split view by holding down the Ctrl key while clicking on the table icon in the lower left corner of the View Area. The two different views are linked together. This means that when you click once on an entry in the table, the Track List will jump the selected region. With the Zoom to Selection button it is possible to jump to and zoom in on the selected region (figure 33.21).

The results of any statistical test executed on the experiment, including fold-changes and p-values, can be seen in the tooltip when hovering over each region in the annotation track shown in the Track List (figure 33.22).

Appendix
Appendix A

Graph preferences

This section explains the view settings of graphs. The Graph preferences at the top of the Side Panel includes the following settings:

- **Lock axes** This will always show the axes even though the plot is zoomed to a detailed level.

- **Frame** Shows a frame around the graph.

- **Show legends** Shows the data legends.

- **Tick type** Determine whether tick lines should be shown outside or inside the frame.
  - Outside
  - Inside

- **Tick lines at** Choosing Major ticks will show a grid behind the graph.
  - None
  - Major ticks

- **Horizontal axis range** Sets the range of the horizontal axis (x axis). Enter a value in Min and Max, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.

- **Vertical axis range** Sets the range of the vertical axis (y axis). Enter a value in Min and Max, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.

- **X-axis at zero.** This will draw the x axis at y = 0. Note that the axis range will not be changed.

- **Y-axis at zero.** This will draw the y axis at x = 0. Note that the axis range will not be changed.

- **Show as histogram.** For some data-series it is possible to see the graph as a histogram rather than a line plot.
The **Lines and plots** below contains the following settings:

- **Dot type**
  - None
  - Cross
  - Plus
  - Square
  - Diamond
  - Circle
  - Triangle
  - Reverse triangle
  - Dot

- **Dot color.** Allows you to choose between many different colors. Click the color box to select a color.

- **Line width**
  - Thin
  - Medium
  - Wide

- **Line type**
  - None
  - Line
  - Long dash
  - Short dash

- **Line color.** Allows you to choose between many different colors. Click the color box to select a color.

For graphs with multiple data series, you can select which curve the dot and line preferences should apply to. This setting is at the top of the **Side Panel** group.

Note that the graph title and the axes titles can be edited simply by clicking with the mouse. These changes will be saved when you **Save** the graph - whereas the changes in the **Side Panel** need to be saved explicitly (see section 4.6).
Appendix B

BLAST databases

Several databases are available at NCBI, which can be selected to narrow down the possible BLAST hits.

B.1 Peptide sequence databases

- **nr.** Non-redundant GenBank CDS translations + PDB + SwissProt + PIR + PRF, excluding those in env_nr.
- **swissprot.** Last major release of the SWISS-PROT protein sequence database (no incremental updates).
- **pat.** Proteins from the Patent division of GenBank.
- **pdb.** Sequences derived from the 3-dimensional structure records from the Protein Data Bank [http://www.rcsb.org/pdb/](http://www.rcsb.org/pdb/).
- **env_nr.** Non-redundant CDS translations from env_nt entries.
- **month.** All new or revised GenBank CDS translations + PDB + SwissProt + PIR + PRF released in the last 30 days..

B.2 Nucleotide sequence databases

- **nr.** All GenBank + EMBL + DDBJ + PDB sequences (but no EST, STS, GSS, or phase 0, 1 or 2 HTGS sequences). No longer "non-redundant" due to computational cost.
- **refseq_rna.** mRNA sequences from NCBI Reference Sequence Project.
- **refseq_genomic.** Genomic sequences from NCBI Reference Sequence Project.
- **est.** Database of GenBank + EMBL + DDBJ sequences from EST division.
- **est_human.** Human subset of est.
APPENDIX B. BLAST DATABASES

- **est_mouse.** Mouse subset of est.
- **est_others.** Subset of est other than human or mouse.
- **gss.** Genome Survey Sequence, includes single-pass genomic data, exon-trapped sequences, and Alu PCR sequences.
- **htgs.** Unfinished High Throughput Genomic Sequences: phases 0, 1 and 2. Finished, phase 3 HTG sequences are in nr.
- **pat.** Nucleotides from the Patent division of GenBank.
- **pdb.** Sequences derived from the 3-dimensional structure records from Protein Data Bank. They are NOT the coding sequences for the corresponding proteins found in the same PDB record.
- **month.** All new or revised GenBank+EMBL+DDBJ+PDB sequences released in the last 30 days.
- **alu.** Select Alu repeats from REPBASE, suitable for masking Alu repeats from query sequences. See "Alu alert" by Claverie and Makalowski, Nature 371: 752 (1994).
- **dbsts.** Database of Sequence Tag Site entries from the STS division of GenBank + EMBL + DDBJ.
- **chromosome.** Complete genomes and complete chromosomes from the NCBI Reference Sequence project. It overlaps with refseq_genomic.
- **wgs.** Assemblies of Whole Genome Shotgun sequences.
- **env_nt.** Sequences from environmental samples, such as uncultured bacterial samples isolated from soil or marine samples. The largest single source is Sagarsso Sea project. This does overlap with nucleotide nr.

### B.3 Adding more databases

Besides the databases that are part of the default configuration, you can add more databases located at NCBI by configuring files in the Workbench installation directory.

In order to add a new database, find the settings folder in the Workbench installation directory (e.g. C:\Program files\CLC Genomics Workbench 4). Download unzip and place the following files in this directory to replace the built-in list of databases:

- **Nucleotide databases:** [http://www.resources.qiagenbioinformatics.com/wbsettings/NCBI_BlastNucleotideDatabases.zip](http://www.resources.qiagenbioinformatics.com/wbsettings/NCBI_BlastNucleotideDatabases.zip)
- **Protein databases:** [http://www.resources.qiagenbioinformatics.com/wbsettings/NCBI_BlastProteinDatabases.zip](http://www.resources.qiagenbioinformatics.com/wbsettings/NCBI_BlastProteinDatabases.zip)
Open the file you have downloaded into the settings folder, e.g. NCBI_BlastProteinDatabases.properties in a text editor and you will see the contents look like this:

nr[clcdefault] = Non-redundant protein sequences
refseq_protein = Reference proteins
swissprot = Swiss-Prot protein sequences
pat = Patented protein sequences
pdb = Protein Data Bank proteins
env_nr = Environmental samples
month = New or revised GenBank sequences

Simply add another database as a new line with the first item being the database name taken from https://web.archive.org/web/20120409025527/http://www.ncbi.nlm.nih.gov/staff/tao/URLAPI/remote_blastdblist.html and the second part is the name to display in the Workbench. Restart the Workbench, and the new database will be visible in the BLAST dialog.
Appendix C

Proteolytic cleavage enzymes

Most proteolytic enzymes cleave at distinct patterns. Below is a compiled list of proteolytic enzymes used in CLC Genomics Workbench.

Restriction enzymes database configuration

CLC Genomics Workbench uses enzymes from the REBASE restriction enzyme database at http://rebase.neb.com. If you wish to add enzymes to this list, you can do this by manually using the procedure described here.

Note! Please be aware that this process needs to be handled carefully, otherwise you may have to re-install the Workbench to get it to work.

First, download the following file: http://www.resources.qiagenbioinformatics.com/wbsettings/link_emboss_e_custom. In the Workbench installation folder under settings, create a folder named rebase and place the extracted link_emboss_e_custom file here.

Note that in macOS, the extension file "link_emboss_e_custom" will have a ".txt" extension in its filename and metadata that needs to be removed. Right click the file name, choose "Get info" and remove ".txt" from the "Name & extension" field.

Open the file in a text editor. The top of the file contains information about the format, and at the bottom there are two example enzymes that you should replace with your own.

Please note that the CLC Workbenches only support the addition of 2-cutter enzymes. Further details about how to format your entries accordingly are given within the file mentioned above.

After adding the above file, or making changes to it, you must restart the Workbench for changes to take effect.
Appendix E

Technical information about modifying Gateway cloning sites

The CLC Genomics Workbench comes with a pre-defined list of Gateway recombination sites. These sites and the recombination logics can be modified by downloading and editing a properties file. Note that this is a technical procedure only needed if the built-in functionality is not sufficient for your needs.

The properties file can be downloaded from http://www.resources.qiagenbioinformatics.com/wbsettings/gatewaycloning.zip. Extract the file included in the zip archive and save it in the settings folder of the Workbench installation folder. The file you download contains the standard configuration. You should thus update the file to match your specific needs. See the comments in the file for more information.

The name of the properties file you download is gatewaycloning.1.properties. You can add several files with different configurations by giving them a different number, e.g. gatewaycloning.2.properties and so forth. When using the Gateway tools in the Workbench, you will be asked which configuration you want to use (see figure E.1).

Appendix H

Complex variant representations and VCF reference overlap

Allelic variants that overlap but do not cover the same range are called complex variants. Whenever two independently called variant sets are joined, there is a chance of getting complex variants. Complex variants comprise 1.4% of variants called by the CLC Fixed Ploidy Variant Detection tool. The popular GATK haplotype caller also encounters this phenomenon.

It is tricky to describe complex variants in VCF, since they have to be written on different lines due to their position, while they also need to be specified in the genotype field of each line without referring to the other lines. It may be possible to extend or split overlapping variants to match each other’s position, in order to comply with the VCF format, however that will lead to inaccuracies when assigning attributes, such as read count and coverage, to the altered variants.

GATK4 outputs complex variants with a genotype field that includes a reference allele for each overlapping allele, thereby also indicating that the variant is heterozygous. Since it means that two VCF lines will contradict each other, it can be argued that this representation is counter-intuitive. RTG tools’ vcfeval provides an option called "–ref-overlap" to handle this representation. When interpreting complex variants represented this way, in case of conflict, non-reference alleles trump reference alleles.

To allow flexibility for communication with variant tracks, we provide the users with the following representation options for the VCF Export tool:

- The reference overlap representation as described above, where reference alleles are added to the genotype field of complex variants. We refer to this as the "Reference overlap" option. We also provide a version of the "Reference overlap" option with allele depth estimation.
- The legacy VCF export format (as available in previous versions of the software)
- The star allele format, based on the star allele introduced in VCF v4.2.

All of these complex variant representations can be handled by the VCF Import tool. A comparison of the options available is presented in figure H.1:
### Without overlap specification

This is the representation used previously, where only variants that are present at the exact same ref positions are specified in the VCF genotype field. Variants that partially overlap do not affect the genotype field. Using this complex variant representation, two types of information are not available in the genotype field that is available for non-complex variants: zygosity of the variant, and the ploidy of the sample at the position.

Suggested use cases: export of database variants without sample specific annotations (such as ClinVar), where specification of sample haplotype structure is not necessary. Also use for applications tailored to handle this legacy format.

### Reference overlap

This representation both allow specification of zygosity, ploidy, and phasing in the genotype field, as well as exact read support and length for complex reference alleles. At positions with complex alternate variants, a reference allele is specified in the VCF genotype field for each reference and alternate allele overlapping the position, these are termed reference overlap alleles. The allele depth is left at zero for reference overlap alleles, indicating that they are merely placeholders for overlapping alleles. The length and allele depth of complex reference alleles are specified separately, so the properties they have in the variant track are retained.

Suggested use cases: this should be the general first choice, since it is an accurate representation of the variants, widely compatible with downstream applications.

### Reference overlap with depth estimate

This is the most compliant representation, where both the genotype and allele depth fields consider all alleles that overlap the position. In VCF files using the AD field for read count, it is common to be able to calculate allele frequency using the formula: \( \text{frequency} = \frac{\text{AD}}{\text{sum(AD)}} \), and that is also possible using this complex variant representation. The reference allele depth represents the combined read depth of overlapping alleles and reference alleles at the position, and is estimated as total read coverage (DP field) minus the combined allele depth of the ALT alleles at the position. This representation only specifies reference alleles together with alternate alleles. The main disadvantage of this representation is that it is not possible to specify exactly what the read support is for a complex reference allele, due to the fact that the reference allele depth is mixed with the overlapping allele depth. Complex reference alleles will get an average allele depth of the overlapping and reference alleles that are present at a position.

---

**Figure H.1: Main characteristics of the complex variant representations.**

<table>
<thead>
<tr>
<th>Advantage</th>
<th>Without overlap specification</th>
<th>Reference overlap</th>
<th>Reference overlap with depth estimate</th>
<th>Star alleles</th>
</tr>
</thead>
<tbody>
<tr>
<td>Allele depth (read count) format field</td>

<td>no</td>
<td>yes</td>
</tr>
<tr>
<td>Can be used in other applications without special consideration of complex reference alleles</td>
<td>yes</td>
<td>yes/no</td>
<td>no</td>
<td>yes</td>
</tr>
</tbody>
</table>

1. The AD field is used if allele fraction can be calculated based on allele depth alone. If the DP field is also required, then the CLCA02 field is used.
2. For databases where no sample allele depth is available, reference overlap may in some situations merge or switch the reference alleles in complex variants.
3. Removal of reference alleles with zero allele depth may be necessary. Many applications ignore reference alleles, so often the added reference overlap alleles will not require any special attention.

---
Suggested use cases: export of variants for use in applications that cannot handle the more accurate "Reference overlap" representation

**Star alleles** According to the VCF specification, star alleles are reserved for overlapping deletions, however some applications treat these in a way that is applicable to all types of overlapping variants. Since the overlapping deletion is defined in another VCF line, and it is unclear if the star allele signifies that the whole position is covered by the deletion, it is sometimes not appropriate to treat the star allele as an actual variant. The star allele can be interpreted merely as providing genotype information for the position, such as zygosity, ploidy, phasing and allele frequencies, whereas the actual overlapping variant will be dealt with at its start position where it is described in detail. This is the way the star allele is interpreted during VCF import in the CLC workbench. When using the star allele complex variant representation it is important to check if the variants are used in an application that handles the star alleles in a way similar to how the CLC workbench does, or if the star alleles are interpreted as actual deletion variants. In the latter case, another complex variant representation should be considered. This representation estimates the star allele depth, i.e. the number of reads supporting the overlapping alleles, to be the difference between the total read coverage and the combined allele depth of the variants at the position. Thus, the allele fraction can be calculated based on allele depth alone, and therefore the AD field is used for allele depth.

Suggested use cases: This representation is accurate and does not require any special reference allele handling (no reference overlap). It should be used for all applications that handle star alleles as described above.

An example of export and import using the different complex variant representations is shown in figure H.2:

![Example of export and import using the different complex variant representations.](image)

Figure H.2: Example of export and import using the different complex variant representations.
H.1 Import of complex variants with reference overlap

It can be specified that variants are represented using reference overlap by adding the line "##refOverlap=true" in the VCF header. If no such line is found in the header, the default is "false", i.e., that no reference overlap alleles are present that need to be replaced by overlapping alleles. Note: Filtered variant positions may interfere in reference overlap processing and should be removed from VCF files prior to reference overlap import.

Detection of complex regions When reading a reference overlap VCF file, a complex region is initiated when overlapping alleles are called on different VCF lines. Complex regions can contain hundreds of complex variants, for example if one allele has a long deletion. Alleles overlap if they share a reference nucleotide position. Insertions overlap non-insertion if they are positioned internally, not if they are positioned at either boundary.

Replacing reference overlap alleles in complex regions For each position with a complex alternate allele, a number of placeholder reference overlap alleles (refoPloidy) are expected to be present, so that the total number of alleles in the genotype field is equal to the ploidy at that position in the sample genome. For each such position in the complex region, it is then determined how many reference overlap alleles are replaced by overlapping alternate and reference alleles (numReplaced). If any reference overlap alleles remain, they are assigned the allele depth: \( \text{newAD} = \frac{\text{origAD} \times (\text{refoPloidy}-\text{numReplaced})}{\text{refoPloidy}} \), where origAD is the original allele depth for all reference overlap alleles at the position. In the "Reference overlap and depth estimate" example above (Table 2), the allele depth of the re-imported reference variant will be: \( \text{newAD} = 6 \times (2-1)/2 = 3 \). In the "Reference overlap" example above (Table 2), no reference overlap alleles will remain (numReplaced=2).

Alternative import of "Reference overlap" representation The method above can be used for both "Reference overlap" and "Reference overlap with depth estimate" representations. However, a VCF file generated with the "Reference overlap" representation can also be imported correctly by simply importing as if it has no reference overlap, and subsequently removing all reference alleles with zero CLCAD2 allele depth.
Appendix I

Formats for import and export

I.1 List of bioinformatic data formats

Below is a list of bioinformatic data formats, i.e. formats for importing and exporting molecule structures, sequences, alignments and trees.

I.1.1 Sequence data formats

Note that high-throughput sequencing data formats from Illumina, IonTorrent, 454 and also high-throughput fasta and trace files are imported using a special import as described in section 6.3. These data can also be exported in fastq format (using NCBI/Sanger Phred quality scores).

</tr>
<tr>
<td>CLC Assembly File</td>
<td>.cas</td>
<td></td>
<td></td>
<td>Output from the CLC Assembly Cell Sequence Alignment/Map. See details in section 6.3.8</td>
</tr>
<tr>
<td>SAM</td>
<td>.sam</td>
<td>X</td>
<td>X</td>
<td>Detailed per-base info on coverage (see below)</td>
</tr>
<tr>
<td>Mapping coverage</td>
<td>.tsv</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Note about BAM export** Index files can be created as part of BAM exports.

**Note about AGP format** Both sequence lists and contigs with reads mapped can be used. Based on annotations of type Scaffold (which are automatically added when running the de novo assembly with the scaffold option), the contigs are broken up before exported as fasta. The agp file produced holds information about how the contigs relate to each other.

**Export of coverage information from sequence alignments** Coverage information from read mappings can be exported in a tabular format using the Mapping coverage export. The output contains information on the number of nucleotides aligned to positions in reference sequences. Insertions are also reported as described below while deletions are reported as reference regions without read coverage. Both stand-alone read mappings and reads tracks can be used as input.

The exported file contains the following columns:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Reference name</td>
</tr>
<tr>
<td>2</td>
<td>Reference position</td>
</tr>
<tr>
<td>3</td>
<td>Reference sub-position (insertion)</td>
</tr>
<tr>
<td>4</td>
<td>Reference symbol</td>
</tr>
<tr>
<td>5</td>
<td>Number of A's</td>
</tr>
<tr>
<td>6</td>
<td>Number of C's</td>
</tr>
<tr>
<td>7</td>
<td>Number of G's</td>
</tr>
<tr>
<td>8</td>
<td>Number of T's</td>
</tr>
<tr>
<td>9</td>
<td>Number of N’s</td>
</tr>
<tr>
<td>10</td>
<td>Number of Gaps</td>
</tr>
<tr>
<td>11</td>
<td>Total number of reads covering the position</td>
</tr>
</tbody>
</table>

The Reference sub-position column is empty (indicated by a - symbol) when the reference is defined at a given position. In case of an insertion this column contains an index into the insertion (a number between 1 and the length of the insertion) while the Reference symbol column is empty and the Reference position column contains the position of the last reference.
## I.1.3 Alignment formats

I.1.6 Annotation and variant formats

Please note that all of the annotation and variant formats can be imported as tracks (see section 6.2). GFF, GVF and GTF formats can also be imported as annotations on a standard (i.e., non-track) sequence or sequence list using functionality provided by the Annotate with GFF plugin (http://www.qiagenbioinformatics.com/plugins/annotate-with-gff-file/).

Special note on former VCF export

In CLC Genomics Workbench 6.5 instead of the CLCAD2, the CLCAD field had been reported. The difference between CLCAD and CLCAD2 is that the former is following the order in the GT (genotype) field in VCF, while the latter is following the order of the REF and ALT fields in VCF in is therefore more in line with the AD field reported from GATK and other sources.

Special notes on VCF import

Note! Please also see section 6.2.

The import process for VCF files into the CLC Genomics Workbench currently work as follows:

1. In cases where GT = ./., no variants are imported at all.
2. In cases where GT = X/. or GT = ./X , and where X is not zero, a single variant is imported depending on the actual value of X.
3. In cases where GT = X/X and X is not zero, in Genomics Workbench 6.5 this will result in two independent variants. In version 6.5.1 they will be reported as a single homozygous
4. In cases where \( GT = X/Y \) and \( X \) and \( Y \) are different but either one may be zero, two independent variants are created.

Please note that some replacements cannot be interpreted in versions that are older than CLC Genomics Workbench 7.0; such replacements will therefore not be imported in previous versions of CLC Genomics Workbench.

An example of these types of replacements are the following:

```
chr2 32843292 . TTTA T,T TT 100 PASS DP=44
```

Due to the VCF interpretation, the initial T base is removed from all alternatives.

In version 6.5.x, only the reference allele (TTA -> TTA) and the first deletion in ALT (TTA -> -) will be imported. The replacements TTA -> TT will not be imported.

In version 7.0 and later versions, all variants will be imported, but the replacements TTA -> TT will be imported as one deletion A -> -.

To get a variant count as part of your imported variant, one of the following VCF tags have to be present in your VCF file: CLCAD2, AD, or AO.

The import of CLCAD2/AD/AO tags are prioritized in the following order:

1. CLCAD2
2. AD
3. AO

If the CLCAD2 is missing, and only AD is present, then AD is used in the "count" column.

The consequence of this, if the file for example has CLCAD2:AD, and in a sample for three possible variants the values are 2,3,4:5,6,7, then the CLCAD2 tag will be imported as count, so each of the three variants will have just one count value (2, 3, and 4 respectively). At the same time, the AD tag will be imported as an annotation so all of the three variants will have "5,6,7" under the AD column, like for any unknown format tag.

**Special notes on chromosome names synonyms used during import**

When importing annotations as tracks, we try to make things simple for the user by having a set of chromosome names that are recognized as synonyms. The check on the chromosome name comparison is made by looking through the chromosomes in the order in which they are registered in the genome. The first match with any of the synonym names for a given chromosome is the chromosome to which the information will be added.

The synonyms applied are:

**For any number \( N \) between (including) 1 and 22:**

\( N \), chr\( N \), chromosome_\( N \), and NC_00000\( N \) are seen as meaning the same thing. As concrete examples:

\( 1 == \text{chr1} == \text{chromosome}_1 == \text{NC_000001} \)
22 == chr22 == chromosome_22 == NC_000022

For any number N larger than 23:
N, chrN, chromosome_N are seen as meaning the same thing. As a concrete example:
26 == chr26 == chromosome_26

For chromosome names with letters, not numbers:
X, chrX, and chromosome_X and NC_000023 are synonyms.
Y, chrY, chromosome_Y and NC_000024 are synonyms.
M, MT, chrM, chrMT, chromosome_M, chromosome_MT and NC_001807 are synonyms.

The accession numbers in the listings above (NC_XXXXX) allow for the matching against NCBI
hg19 human reference names against the names used by USCS and vitally, the names used
by Ensembl. Thus, in this case, if you have the correct number of chromosomes in a human
reference (i.e. 25 references, including the hg19 mitochondria), that set of tracks can be used
as the basis for downloading/importing annotations via Download Genomes, for example.

Note: These rules only apply for importing annotations as tracks, whether that is directly or via
Download Genomes. Synonyms are not applied when doing BAM imports or when using the
Annotate with GFF plugin. There, your reference names in the Workbench must exactly match the
references names used in your BAM file or GFF/GTF/GVF file respectively.

Appendix J

SAM/BAM export format specification

SAM Specification The workbench aims to import and export SAM and BAM files according to the v1.4-r962 version of the SAM specification (see http://samtools.sourceforge.net/SAM1.pdf). This appendix describes how the workbench exports SAM and BAM files along with known limitations.

SAM and BAM Export - General notes The SAM exporter writes unsorted SAM and BAM files.

If the reference name contains spaces, the spaces are removed. Each occurrence of '=' (equals sign) and '@' (at sign) in a reference name is replaced by an '_' (underscore).

The SAM importer and exporter support the ID, SM, PI and PL read group tags. All other read group tags are ignored.

The BAM exporter can also output additional annotations added by tools provided by plugins, and where that is the case, further details are provided in the plugin manual.

SAM Alignment Section A few remarks on the exported alignment section:

- Unmapped reads are not exported.
- If pairs are not on the same contig, the mates will be exported as single reads.
- Multi segment mappings will be imported as a paired data set.
- If a read name contains spaces, the spaces are replaced by an underscore '_'.
- The exported CIGAR string uses 'M' to indicate match or mismatch and does not use '=' (equals sign) or 'X'.
- CLC software does not support or record mapping quality for read mappings. To fulfill the requirement in the BAM format specifications that a read mapping quality is recorded for all mapped reads, the values 0 and 60 are used when mappings are exported from the Workbench. The value 60 is given to reads that mapped uniquely. The value 0 is given to reads that could map equally well to other locations besides the one being reported in the BAM file.

Optional fields in the alignment section The following is true for the export of optional fields:
• The NH tag is exported.
• The NM tag is not exported.

### J.1 Flags

The workbench’s use of the alignment flags is shown in the following table and subsequent examples.

<table>
<thead>
<tr>
<th>Bit</th>
<th>SAM description</th>
<th>Usage in Workbench</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x1</td>
<td>template having multiple segments in sequencing</td>
<td>set if the segment is part of a pair</td>
</tr>
<tr>
<td>0x2</td>
<td>each segment properly aligned according to the aligner</td>
<td>set if the pair is not broken</td>
</tr>
<tr>
<td>0x4</td>
<td>segment unmapped</td>
<td>never set since the exporter does not export unmapped reads</td>
</tr>
<tr>
<td>0x8</td>
<td>next segment in the template unmapped</td>
<td>never set by the exporter. If a segment has an unmapped mate, the flag 0x1 is not set for the segment, i.e. it is not output as part of a pair</td>
</tr>
<tr>
<td>0x10</td>
<td>SEQ being reverse complemented</td>
<td>set if and only if the segment was reverse complemented during mapping</td>
</tr>
<tr>
<td>0x20</td>
<td>SEQ of the next segment in the template being reversed</td>
<td>set if and only if the mate was reverse complemented during mapping</td>
</tr>
<tr>
<td>0x40</td>
<td>the first segment in the template</td>
<td>this mate is the first segment of the pair</td>
</tr>
<tr>
<td>0x80</td>
<td>the last segment in the template</td>
<td>this mate is the second segment of the pair</td>
</tr>
<tr>
<td>0x100</td>
<td>secondary alignment</td>
<td>never set by the exporter. No reads with this flag set are imported(^1).</td>
</tr>
<tr>
<td>0x200</td>
<td>not passing quality controls</td>
<td>never set by the exporter and ignored by the importer</td>
</tr>
<tr>
<td>0x400</td>
<td>PCR or optical duplicate</td>
<td>never set by the exporter and ignored by the importer</td>
</tr>
</tbody>
</table>

#### Flag Examples

The following table illustrates some of the possible flags in the workbench.

\(^1\)The representation of a particular read with more than one location in a mapping is not supported in the software and thus cannot be imported.
<table>
<thead>
<tr>
<th>Description of the example</th>
<th>Bits</th>
<th>Flag</th>
<th>Illustration</th>
</tr>
</thead>
<tbody>
<tr>
<td>The first mate of a non-broken paired read</td>
<td>0x1, 0x2, 0x20, 0x40</td>
<td>99</td>
<td>See figure J.1</td>
</tr>
<tr>
<td>The second mate of a non-broken paired read</td>
<td>0x1, 0x2, 0x10, 0x80</td>
<td>147</td>
<td>See figure J.2</td>
</tr>
<tr>
<td>A single, forward read (or paired read, where only one mate of the pair is mapped)</td>
<td>No set bits</td>
<td>0</td>
<td>see figure J.3</td>
</tr>
<tr>
<td>A single, reversed read (or paired read, where only one mate of the pair is mapped)</td>
<td>0x10</td>
<td>16</td>
<td>See figure J.4</td>
</tr>
<tr>
<td>The first, forward segment from a broken pair with forward mate</td>
<td>0x1, 0x40</td>
<td>65</td>
<td>See figure J.5</td>
</tr>
<tr>
<td>The second, forward segment from broken pair with reversed mate</td>
<td>0x1, 0x20, 0x80</td>
<td>161</td>
<td>See figure J.6</td>
</tr>
<tr>
<td>The first, reversed segment from broken pair with forward mate</td>
<td>0x1, 0x10, 0x40</td>
<td>81</td>
<td>See figure J.7</td>
</tr>
<tr>
<td>The second, reversed segment from broken pair with reversed mate</td>
<td>0x1, 0x10, 0x20, 0x80</td>
<td>177</td>
<td>See figure J.8</td>
</tr>
</tbody>
</table>

Figure J.1: The read is paired, both reads are mapped and the mate of this read is reversed

Figure J.2: The read is paired, both mates are mapped, and this segment is reversed

Figure J.3: A single, forward read, or a paired read where the mate is not mapped
Figure J.4: The read is a single, reversed read, or a paired read where the mate is not mapped

Figure J.5: These forward reads are paired. They map to the same place, so the pair is broken

Figure J.6: Forward read that is part of a broken read where the mate is reversed

Figure J.7: Reversed read that is part of a broken pair, where the mate is forward

Figure J.8: Reversed read that is part of a broken pair, where the mate is also reversed.
Appendix K

Gene expression annotation files and microarray data formats

The workbench supports analysis of one-color expression arrays. These may be imported from GEO soft sample- or series- file formats, or for Affymetrix arrays, tab-delimited pivot or metrics files, or from Illumina expression files. Expression array data from other platforms may be imported from tab, semi-colon or comma separated files containing the expression feature IDs and levels in a tabular format (see section K.5).

The workbench assumes that expression values are given at the gene level, thus probe-level analysis of e.g. Affymetrix GeneChips and import of Affymetrix CEL and CDF files is currently not supported. However, the workbench allows import of txt files exported from R containing processed Affymetrix CEL-file data (see see section K.2).

Affymetrix NetAffx annotation files for expression GeneChips in csv format and Illumina annotation files can also be imported. Also, you may import your own annotation data in tabular format see section K.5).

Below you find descriptions of the microarray data formats that are supported by CLC Genomics Workbench. Note that we for some platforms support both expression data and annotation data.

K.1 GEO (Gene Expression Omnibus)

The GEO (Gene Expression Omnibus) sample and series formats are supported. Figure K.1 shows how to download the data from GEO in the right format. GEO is located at http://www.ncbi.nlm.nih.gov/geo/.

The GEO sample files are tab-delimited .txt files. They have three required lines:

```
^SAMPLE = GSM21610
!sample_table_begin
...
!sample_table_end
```

The first line should start with ^SAMPLE = followed by the sample name, the line !sample_table_begin and the line !sample_table_end. Between the !sample_table_begin and !sample_table_end,
Figure K.1: Selecting Samples, SOFT and Data before clicking go will give you the format supported by the CLC Genomics Workbench.

Note that GEO sample importer will also work for concatenated GEO sample files — allowing multiple samples to be imported in one go. Download a sample file containing concatenated sample files here:
http://www.resources.qiagenbioinformatics.com/madata/GEOSampleFilesConcatenated.txt

Below you can find examples of the formatting of the GEO formats.

**K.1.1 GEO sample file, simple**

This format is very simple and includes two columns: one for feature id (e.g. gene name) and one for the expression value.

```
^SAMPLE = GSM21610
!sample_table_begin
ID_REF VALUE
id1  105.8
id2   32
id3  50.4
id4  57.8
id5 2914.1
!sample_table_end
```

Download the sample file here:
http://www.resources.qiagenbioinformatics.com/madata/GEOSampleFileSimple.txt

**K.1.2 GEO sample file, including present/absent calls**

This format includes an extra column for absent/present calls that can also be imported.

```
^SAMPLE = GSM21610
!sample_table_begin
```

APPENDIX K. GENE EXPRESSION ANNOTATION FILES AND MICROARRAY DATA FORMATS

K.1.3 GEO sample file, including present/absent calls and p-values

This format includes two extra columns: one for absent/present calls and one for absent/present call p-values, that can also be imported.

```
^SAMPLE = GSM21610
!sample_table_begin
ID_REF  VALUE  ABS_CALL  DETECTION  P-VALUE
id1     105.8   M        0.00227496
id2     32      A        0.354441
id3     50.4    A        0.904352
id4     57.8    A        0.937071
id5     2914.1  P        6.02111e-05
!sample_table_end
```

Download the sample file here:
http://www.resources.qiagenbioinformatics.com/madata/GEOSampleFileAbsentPresentCallAndPValue.txt

K.1.4 GEO sample file: using absent/present call and p-value columns for sequence information

The workbench assumes that if there is a third column in the GEO sample file then it contains present/absent calls and that if there is a fourth column then it contains p-values for these calls. This means that the contents of the third column is assumed to be text and that of the fourth column a number. As long as these two basic requirements are met, the sample should be recognized and interpreted correctly.

You can thus use these two columns to carry additional information on your probes. The absent/present column can be used to carry additional information like e.g. sequence tags as shown below:

```
^SAMPLE = GSM21610
!sample_table_begin
ID_REF  VALUE  ABS_CALL
id1     105.8   AAA
```
id2 32 AAC
id3 50.4 ATA
id4 57.8 ATT
id5 2914.1 TTA

Download the sample file here:
http://www.resources.qiagenbioinformatics.com/madata/GEOSampleFileSimpleSequenceTag.txt

Or, if you have multiple probes per sequence you could use the present/absent column to hold the sequence name and the p-value column to hold the interrogation position of your probes:

^KSAMPLE = GSM21610
!sample_table_begin
ID_REF VALUE ABS_CALL DETECTION P-VALUE
probe1 755.07 seq1 1452
probe2 587.88 seq1 497
probe3 716.29 seq1 1447
probe4 1287.18 seq2 1899
!sample_table_end

Download the sample file here:
http://www.resources.qiagenbioinformatics.com/madata/GEOSampleFileSimpleSequenceTagAndProbe.txt

K.1.5 GEO series file, simple

The series file includes expression values for multiple samples. Each of the samples in the file will be represented by its own element with the sample name. The first row lists the sample names.

^KSAMPLE = GSM21610
!Series_title "Myb specificity determinants"
!series_matrix_table_begin
"ID_REF" "GSM21610" "GSM21611" "GSM21612"
"id1" 2541 1781.8 1804.8
"id2" 11.3 621.5 50.2
"id3" 61.2 149.1 22
"id4" 55.3 328.8 97.2
"id5" 183.8 378.3 423.2
!series_matrix_table_end

Download the sample file here:
http://www.resources.qiagenbioinformatics.com/madata/GEOSeriesFile.txt

K.2 Affymetrix GeneChip

For Affymetrix, three types of files are currently supported: Affymetrix .CHP files, Affymetrix NetAffx annotation files and tab-delimited pivot or metrics files. Affymetrix .CEL files are currently not
supported. However, the Bioconductor R package ‘affy’ allows you to preprocess the .CEL files and export a txt file containing a table of estimated probe-level expression values in three lines of code:

```r
library(affy) # loading Bioconductor library ‘affy’
data=ReadAffy() # probe-level data import
eset=rma(data) # probe-level data pre-processing using ‘rma’
write.exprs(eset,file="evals.txt") # writing probe expression levels to ‘evals-txt’
```

The exported txt file (evals.txt) can be imported into the workbench using the Generic expression data table format importer (see section K.5; you can just ‘drag-and-drop’ it in). In R, you should have all the CEL files you wish to process in your working directory and the file ‘evals.txt’ will be written to that directory.

If multiple probes are present for the same gene, further processing may be required to merge them into a single gene-level expression.

### K.2.1 Affymetrix CHP expression files

The Affymetrix scanner software produces a number of files when a GeneChip is scanned. Two of these are the .CHP and the .CEL files. These are binary files with native Affymetrix formats. The Affymetrix GeneChips contain a number of probes for each gene (typically between 22 and 40). The .CEL file contains the probe-level intensities, and the .CHP file contains the gene-level information. The gene-level information has been obtained by the scanner software through postprocessing and summarization of the probe-level intensities.

In order to interpret the probe-level information in the .CEL file, the .CDF file for the type of GeneChip that was used is required. Similarly for the .CHP file: in order to interpret the gene-level information in the .CHP file, the .PSI file for the type of GeneChip that was used is required.

In order to import a .CHP file it is required that the corresponding .PSI file is present in the same folder as the .CHP file you want to import, and furthermore, this must be the only .PSI file that is present there. There are no requirements for the name of the .PSI file. Note that the .PSI file itself will not be imported - it is only used to guide the import of the .CHP file which contains the expression values.

Download example .CHP and .PSI files here (note that these are binary files):
http://www.resources.qiagenbioinformatics.com/madata/AffymetrixCHPandPSI.zip

### K.2.2 Affymetrix metrix files

The Affymetrix metrics or pivot files are tab-delimited files that may be exported from the Affymetrix scanner software. The metrics files have a lot of technical information that is only partly used in the Workbench. The feature ids (Probe Set Name), expression values (Used Signal), absent/present call (Detection) and absent/present p-value (Detection p-value) are imported into the Workbench.

Download a small example sample file here:
http://www.resources.qiagenbioinformatics.com/madata/AffymetrixMetrics.txt
K.2.3  **Affymetrix NetAffx annotation files**

The NetAffx annotation files for Whole-Transcript Expression Gene arrays and 3’ IVT Expression Analysis Arrays can be imported and used to annotate experiments as shown in section 29.2.3.

Download a small example annotation file here which includes header information:
http://www.resources.qiagenbioinformatics.com/madata/AffymetrixNetAffxAnnotationFile.csv

K.3  **Illumina BeadChip**

Both BeadChip expression data files from Illumina’s BeadStudio software and the corresponding BeadChip annotation files are supported by CLC Genomics Workbench. The formats of the BeadStudio and annotation files have changed somewhat over time and various formats are supported.

K.3.1  **Illumina expression data, compact format**

An example of this format is shown below:

<table>
<thead>
<tr>
<th>TargetID</th>
<th>AVG_Signal</th>
<th>BEAD_STDEV</th>
<th>Detection</th>
</tr>
</thead>
<tbody>
<tr>
<td>GI_10047089-S</td>
<td>112.5</td>
<td>4.2</td>
<td>0.16903226</td>
</tr>
<tr>
<td>GI_10047091-S</td>
<td>127.6</td>
<td>4.8</td>
<td>0.76774194</td>
</tr>
</tbody>
</table>

All this information is imported into the Workbench. The AVG_Signal is used as the expression measure.

Download a small sample file here:
http://www.resources.qiagenbioinformatics.com/madata/IlluminaBeadChipCompact.txt

K.3.2  **Illumina expression data, extended format**

An example of this format is shown below:

<table>
<thead>
<tr>
<th>TargetID</th>
<th>MIN_Signal</th>
<th>AVG_Signal</th>
<th>MAX_Signal</th>
<th>NARRAYS</th>
<th>ARRAY_STDEV</th>
<th>BEAD_STDEV</th>
<th>Avg_NBeads</th>
<th>Detection</th>
</tr>
</thead>
<tbody>
<tr>
<td>GI_10047089-S</td>
<td>73.7</td>
<td>73.7</td>
<td>73.7</td>
<td>1</td>
<td>NaN</td>
<td>3.4</td>
<td>53</td>
<td>0.05669084</td>
</tr>
<tr>
<td>GI_10047091-S</td>
<td>312.7</td>
<td>312.7</td>
<td>312.7</td>
<td>1</td>
<td>NaN</td>
<td>11.1</td>
<td>50</td>
<td>0.99604483</td>
</tr>
</tbody>
</table>

All this information is imported into the Workbench. The AVG_Signal is used as the expression measure.

Download a small sample file here:
http://www.resources.qiagenbioinformatics.com/madata/IlluminaBeadChipExtended.txt

K.3.3  **Illumina expression data, with annotations**

An example of this format is shown below:

<table>
<thead>
<tr>

</tbody>
</table>
Only the TargetID, Signal and Detection columns will be imported, the remaining columns will be ignored. This means that the annotations are not imported. The Signal is used as the expression measure.

Download a small example sample file here: http://www.resources.qiagenbioinformatics.com/madata/IlluminaBeadStudioWithAnnotations.txt

K.3.4 Illumina expression data, multiple samples in one file

This file format has too much information to show it inline in the text. You can download a small example sample file here:
http://www.resources.qiagenbioinformatics.com/madata/IlluminaBeadStudioMultipleSamples.txt

This file contains data for 18 samples. Each sample has an expression value (the value in the AVG_Signal column), a detection p-value, a bead standard deviation and an average bead number column. The workbench recognizes the 18 samples and their columns.

K.3.5 Illumina annotation files

The Workbench supports import of two types of Illumina BeadChip annotation files. These are either comma-separated or tab-delimited .txt files. They can be used to annotate experiments as shown in section 29.2.3.

This file format has too much information to show it inline in the text.

Download a small example annotation file of the first type here:
http://www.resources.qiagenbioinformatics.com/madata/IlluminaBeadChipAnnotation.txt

K.4 Gene ontology annotation files

The Gene ontology web site provides annotation files for a variety of species which can all be downloaded and imported into the CLC Genomics Workbench. They can be used to annotate experiments as shown in section 29.2.3. They can also be used with the Gene Set Test and Create Expression Browser tools.

Import GO annotation file using the Standard Import tool. For GO annotation files in GAF format, use the option "Force import as type: Gene Ontology Annotation file" from the drop down menu at the bottom of the Standard Import dialog.

See the complete list of available files, including download links, at http://www.geneontology.org/GO.current.annotations.shtml.

K.5 Generic expression and annotation data file formats

If you have your expression or annotation data in Excel and can export the data as a txt file, or if you are able to do some scripting or other manipulations to format your data files, you will be
able to import them into the CLC Genomics Workbench as a 'generic' expression or annotation data file. There are a few simple requirements that need to be fulfilled to do this as described below.

K.5.1 Generic expression data table format

The CLC Genomics Workbench will import a tab, semicolon or comma-separated .txt or .csv file as expression array samples if the following requirements are met:

1. the first non-empty line of the file contains text. All entries, except the first, will be used as sample names
2. the following (non-empty) lines contain the same number of entries as the first non-empty line. The requirements to these are that the first entry should be a string (this will be used as the feature ID) and the remaining entries should contain numbers (which will be used as expression values — one per sample). Empty entries are not allowed, but NaN values are allowed.
3. the file contains at least two samples.

An example of this format is shown below:

```
FeatureID;sample1;sample2;sample3
gene1;200;300;23
gene2;210;30;238
gene3;230;50;23
gene4;50;100;235
gene5;200;300;23
gene6;210;30;238
gene7;230;50;23
gene8;50;100;235
```

This will be imported as three samples with eight genes in each sample.

Download a this example as a file here: [http://www.resources.qiagenbioinformatics.com/madata/CustomExpressionData.txt](http://www.resources.qiagenbioinformatics.com/madata/CustomExpressionData.txt)

K.5.2 Generic annotation file for expression data format

The CLC Genomics Workbench will import a tab, semicolon or comma-separated .txt or .csv file as an annotation file if the following is met:

1. It has a line which can serve as a valid header line. In order to do this, the line should have a number of headers where at least two are among the valid column headers in the Column header column below.
2. It contains one of the PROBE_ID headers (that is: 'Probe Set ID', 'Feature ID', 'ProbelID' or 'Probe_Id').
The importer will import an annotation table with a column for each of the valid column headers (those in the **Column header** column below). Columns with invalid headers will be ignored.

Note that some column headers are alternatives so that only one of the alternative columns headers should be used.

When adding annotations to an experiment, you can specify the column in your annotation file containing the relevant identifiers. These identifiers are matched to the feature ids already present in your experiment. When a match is found, the annotation is added to that entry in the experiment. In other words, at least one column in your annotation file must contain identifiers matching the feature identifiers in the experiment, for those annotations to be applied.

A simple example of an annotation file is shown here:

<table>
<thead>
<tr>
<th>Probe Set ID</th>
<th>Gene Symbol</th>
<th>Gene Ontology Biological Process</th>
</tr>
</thead>
<tbody>
<tr>
<td>1367452_at</td>
<td>Sumo2</td>
<td>0006464 // protein modification process // not recorded</td>
</tr>
<tr>
<td>1367453_at</td>
<td>Cdc37</td>
<td>0051726 // regulation of cell cycle // not recorded</td>
</tr>
<tr>
<td>1367454_at</td>
<td>Copb2</td>
<td>0006810 // transport // 0016044 // membrane organization //</td>
</tr>
</tbody>
</table>

Download this example plus a more elaborate one here:

http://www.resources.qiagenbioinformatics.com/madata/SimpleCustomAnnotation.csv

http://www.resources.qiagenbioinformatics.com/madata/FullCustomAnnotation.csv

To meet requirements imposed by special functionalities in the workbench, there are a number of further restrictions on the contents of the entries of the columns:

**Download sequence functionality** In the experiment table, you can click a button to download sequence. This uses the contents of the **PUBLIC_ID** column, so this column must be present for the action to work and should contain the NCBI accession number.

**Annotation tests** The annotation tests can make use of several entries in a column as long as a certain format is used. The tests assume that entries are separated by /// and it interprets all that appears before // as the actual entry and all that appears after // within an entry as comments. Example:

/// 0000001 // comment1 /// 0000008 // comment2 /// 0003746 // comment3

The annotation tests will interpret this as three entries (0000001, 0000008, and 0003746) with the according comments.

The most common column headers are summarized below:

<table>
<thead>
<tr>
<th>Column header in imported file (alternatives separated by commas)</th>
<th>Label in experiment table</th>
<th>Description (tool tip)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Probe Set ID, Feature ID, ProbeID, Probe_Id, transcript_cluster_id</td>

Appendix L

Custom codon frequency tables

You can edit the list of codon frequency tables used by CLC Genomics Workbench.

Note! Please be aware that this process needs to be handled carefully, otherwise you may have to re-install the Workbench to get it to work.

In the Workbench installation folder under res, there is a folder named codonfreq. This folder contains all the codon frequency tables organized into subfolders in a hierarchy. In order to change the tables, you simply add, delete or rename folders and the files in the folders. If you wish to add new tables, please use the existing ones as template. In existing tables, the "_number" at the end of the "cftbl" file name is the number of CDSs that were used for calculation, according to the http://www.kazusa.or.jp/codon/ site.

When creating a custom table, it is not necessary to fill in all fields as only the codon information (e.g. 'GCG' in the example below) and the counts (e.g. 47869.00) are used when doing reverse translation:

Name: Rattus norvegicus GeneticCode: 1 Ala GCG 47869.00 6.86 0.10 Ala GCA 109203.00 15.64 0.23 ....

In particular, the amino acid type is not used: in order to use an alternative genetic code, it must be specified in the 'GeneticCode' line instead.

Restart the Workbench to have the changes take effect.
## Comparison of track comparison tools

This section of the manual provides an overview about comparison, filtering and annotation tools that work with tracks.
