Welcome to *CLC Main Workbench* — a software package supporting your daily bioinformatics work.

We strongly encourage you to read this user manual in order to get the best possible basis for working with the software package.

This software is for research purposes only.

1.1 Contact information

The *CLC Main Workbench* is developed by:

CLC bio A/S
Science Park Aarhus
Finlandsgade 10-12
8200 Aarhus N
Denmark

<http://www.clcbio.com>

VAT no.: DK 28 30 50 87

Telephone: +45 70 22 55 09

Fax: +45 70 22 55 19

E-mail: info@clcbio.com

If you have questions or comments regarding the program, you are welcome to contact our support function:

E-mail: support@clcbio.com

1.2 Download and installation

The *CLC Main Workbench* is developed for Windows, Mac OS X and Linux. The software for either platform can be downloaded from <http://www.clcbio.com/download>.

1.2.1 Program download

The program is available for download on <http://www.clcbio.com/download>.

Before you download the program you are asked to fill in the **Download** dialog.

In the dialog you must choose:

- Which operating system you use
- Whether you would like to receive information about future releases

Depending on your operating system and your Internet browser, you are taken through some download options.

When the download of the installer (an application which facilitates the installation of the program) is complete, follow the platform specific instructions below to complete the installation procedure. ¹

1.2.2 Installation on Microsoft Windows

Starting the installation process is done in one of the following ways:

¹ You must be connected to the Internet throughout the installation process.

If you have downloaded an installer:

Locate the downloaded installer and double-click the icon.
The default location for downloaded files is your desktop.

If you are installing from a CD:

Insert the CD into your CD-ROM drive.
Choose the "Install CLC Main Workbench" from the menu displayed.

Installing the program is done in the following steps:

- On the welcome screen, click **Next**.
- Read and accept the License agreement and click **Next**.
- Choose where you would like to install the application and click **Next**.
- Choose a name for the Start Menu folder used to launch *CLC Main Workbench* and click **Next**.
- Choose if *CLC Main Workbench* should be used to open CLC files and click **Next**.
- Choose where you would like to create shortcuts for launching *CLC Main Workbench* and click **Next**.
- Choose if you would like to associate .clc files to *CLC Main Workbench*. If you check this option, double-clicking a file with a "clc" extension will open the *CLC Main Workbench*.
- Wait for the installation process to complete, choose whether you would like to launch *CLC Main Workbench* right away, and click **Finish**.

When the installation is complete the program can be launched from the Start Menu or from one of the shortcuts you chose to create.

1.2.3 Installation on Mac OS X

Starting the installation process is done in one of the following ways:

If you have downloaded an installer:

Locate the downloaded installer and double-click the icon.
The default location for downloaded files is your desktop.

If you are installing from a CD:

Insert the CD into your CD-ROM drive and open it by double-clicking on the CD icon on your desktop.

Launch the installer by double-clicking on the "*CLC Main Workbench*" icon.

Installing the program is done in the following steps:

- On the welcome screen, click **Next**.
- Read and accept the License agreement and click **Next**.

- Choose where you would like to install the application and click **Next**.
- Choose if *CLC Main Workbench* should be used to open CLC files and click **Next**.
- Choose whether you would like to create desktop icon for launching *CLC Main Workbench* and click **Next**.
- Choose if you would like to associate .clc files to *CLC Main Workbench*. If you check this option, double-clicking a file with a "clc" extension will open the *CLC Main Workbench*.
- Wait for the installation process to complete, choose whether you would like to launch *CLC Main Workbench* right away, and click **Finish**.

When the installation is complete the program can be launched from your Applications folder, or from the desktop shortcut you chose to create. If you like, you can drag the application icon to the dock for easy access.

1.2.4 Installation on Linux with an installer

Navigate to the directory containing the installer and execute it. This can be done by running a command similar to:

```
# sh CLCMainWorkbench_6_JRE.sh
```

If you are installing from a CD the installers are located in the "linux" directory.

Installing the program is done in the following steps:

- On the welcome screen, click **Next**.
- Read and accept the License agreement and click **Next**.
- Choose where you would like to install the application and click **Next**.
For a system-wide installation you can choose for example /opt or /usr/local. If you do not have root privileges you can choose to install in your home directory.
- Choose where you would like to create symbolic links to the program
DO NOT create symbolic links in the same location as the application.
Symbolic links should be installed in a location which is included in your environment PATH. For a system-wide installation you can choose for example /usr/local/bin. If you do not have root privileges you can create a 'bin' directory in your home directory and install symbolic links there. You can also choose not to create symbolic links.
- Wait for the installation process to complete and click **Finish**.

If you choose to create symbolic links in a location which is included in your PATH, the program can be executed by running the command:

```
# clcmainwb6
```

Otherwise you start the application by navigating to the location where you choose to install it and running the command:

```
# ./clcmainwb6
```

1.2.5 Installation on Linux with an RPM-package

Navigate to the directory containing the rpm-package and install it using the rpm-tool by running a command similar to:

```
# rpm -ivh CLCMainWorkbench_6_JRE.rpm
```

If you are installing from a CD the rpm-packages are located in the "RPMS" directory. Installation of RPM-packages usually requires root-privileges.

When the installation process is finished the program can be executed by running the command:

```
# clcmainwb6
```

1.3 System requirements

The system requirements of *CLC Main Workbench* are these:

- Windows XP, Windows Vista, Windows 7, Windows 8, Windows Server 2003 or Windows Server 2008
- Mac OS X 10.6 or later. However, Mac OS X 10.5.8 is supported on 64-bit Intel systems.
- Linux: Red Hat 5 or later. SUSE 10 or later.
- 32 or 64 bit
- 256 MB RAM required
- 512 MB RAM recommended
- 1024 x 768 display recommended

1.4 Licenses

When you have installed *CLC Main Workbench*, and start it for the first time, you will meet the license assistant, shown in figure 1.1.

Please note that to install a license, you must be running the program in administrative mode ².

The following options are available. They will be described in detail in the following sections.

- **Request an evaluation license.** The license is a fully functional, time-limited license (see below).
- **Download a license.** When you purchase a license, you will get a license ID from CLC bio. Using this option, you will get a license based on this ID.
- **Import a license from a file.** If CLC bio has provided a license file, or if you have downloaded a license from our web-based licensing system, you can import it using this option.

²"How to do this differs for different operating systems. To run the program in administrator mode on Windows Vista, or 7, right-click the program shortcut and choose "Run as Administrator."

Figure 1.1: The license assistant showing you the options for getting started.

- **Upgrade license.** If you already have used a previous version of *CLC Main Workbench*, and you are entitled to upgrading to the new *CLC Main Workbench 6.8*, select this option to get a license upgrade.
- **Configure license server connection.** If your organization has a license server, select this option to connect to the server.

Select an appropriate option and click **Next**.

If for some reason you don't have access to getting a license, you can click the **Limited Mode** button (see section 1.4.6).

1.4.1 Request an evaluation license

We offer a fully functional demo version of *CLC Main Workbench* to all users, free of charge.

Each user is entitled to 30 days demo of *CLC Main Workbench*. If you need more time for evaluating, another two weeks of demo can be requested.

When you select to request an evaluation license, you will see the dialog shown in figure 1.2.

In this dialog, there are two options:

- **Direct download.** The workbench will attempt to contact the online CLC Licenses Service, and download the license directly. This method requires internet access from the workbench.
- **Go to license download web page.** The workbench will open a Web Browser with the License Download web page when you click **Next**. From there you will be able to download your license as a file and import it. This option allows you to get a license, even though the Workbench does not have direct access to the CLC Licenses Service.

Figure 1.2: Choosing between direct download or download web page.

If you select the first option, and it turns out that you do not have internet access from the Workbench (because of a firewall, proxy server etc.), you will be able to click **Previous** and use the other option instead.

Direct download

Selecting the first option takes you to the dialog shown in figure 1.3.

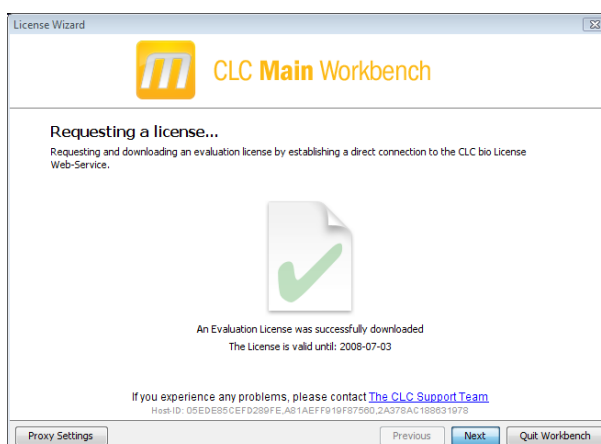

Figure 1.3: A license has been downloaded.

A progress for getting the license is shown, and when the license is downloaded, you will be able to click **Next**.

Go to license download web page

Selecting the second option, *Go to license download web page*, opens the license web page as shown in 1.4.

Click the **Request Evaluation License** button, and you will be able to save the license on your computer, e.g. on the Desktop.

Back in the Workbench window, you will now see the dialog shown in 1.5.

Click the **Choose License File** button and browse to find the license file you saved before (e.g. on your Desktop). When you have selected the file, click **Next**.

Figure 1.4: The license web page where you can download a license.

Figure 1.5: Importing the license downloaded from the web site.

Accepting the license agreement

Regardless of which option you chose above, you will now see the dialog shown in figure 1.6.

Figure 1.6: Read the license agreement carefully.

Please read the License agreement carefully before clicking **I accept these terms** and **Finish**.

1.4.2 Download a license

When you purchase a license, you will get a license ID from CLC bio. Using this option, you will get a license based on this ID. When you have clicked **Next**, you will see the dialog shown in 1.7.

At the top, enter the ID (paste using Ctrl+V or ⌘ + V on Mac).

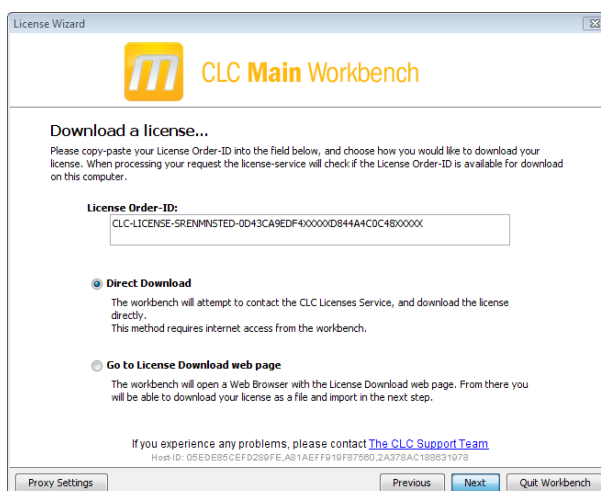

Figure 1.7: Entering a license ID provided by CLC bio (the license ID in this example is artificial).

In this dialog, there are two options:

- **Direct download.** The workbench will attempt to contact the online CLC Licenses Service, and download the license directly. This method requires internet access from the workbench.
- **Go to license download web page.** The workbench will open a Web Browser with the License Download web page when you click **Next**. From there you will be able to download your license as a file and import it. This option allows you to get a license, even though the Workbench does not have direct access to the CLC Licenses Service.

If you select the first option, and it turns out that you do not have internet access from the Workbench (because of a firewall, proxy server etc.), you will be able to click **Previous** and use the other option instead.

Direct download

Selecting the first option takes you to the dialog shown in figure 1.8.

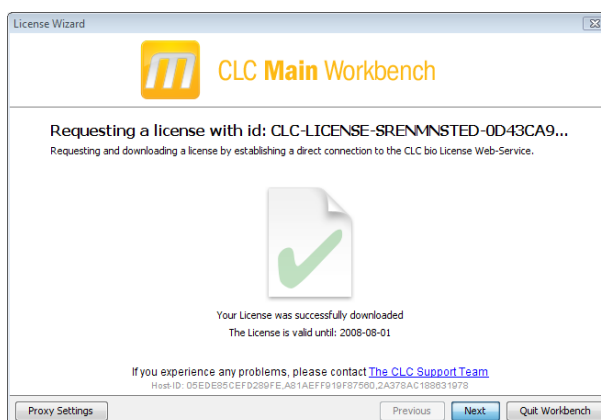

Figure 1.8: A license has been downloaded.

A progress for getting the license is shown, and when the license is downloaded, you will be able to click **Next**.

Go to license download web page

Selecting the second option, *Go to license download web page*, opens the license web page as shown in 1.9.

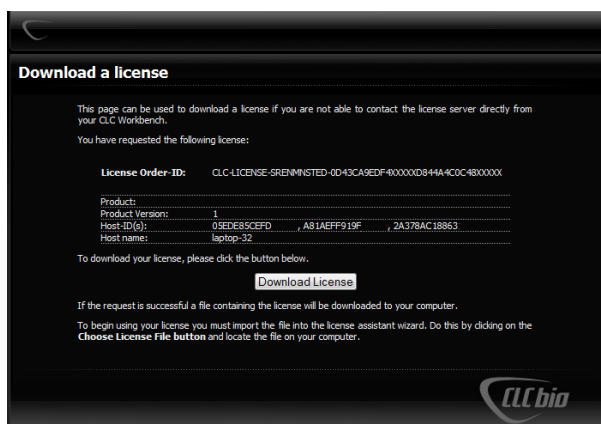

Figure 1.9: The license web page where you can download a license.

Click the **Request Evaluation License** button, and you will be able to save the license on your computer, e.g. on the Desktop.

Back in the Workbench window, you will now see the dialog shown in 1.10.

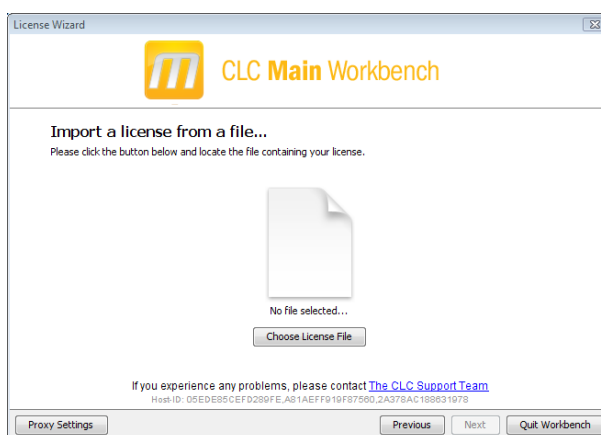

Figure 1.10: Importing the license downloaded from the web site.

Click the **Choose License File** button and browse to find the license file you saved before (e.g. on your Desktop). When you have selected the file, click **Next**.

Accepting the license agreement

Regardless of which option you chose above, you will now see the dialog shown in figure 1.11.

Please read the License agreement carefully before clicking **I accept these terms** and **Finish**.

1.4.3 Import a license from a file

If you are provided a license file instead of a license ID, you will be able to import the file using this option.

Figure 1.11: Read the license agreement carefully.

When you have clicked **Next**, you will see the dialog shown in 1.12.

Figure 1.12: Selecting a license file .

Click the **Choose License File** button and browse to find the license file provided by CLC bio. When you have selected the file, click **Next**.

Accepting the license agreement

Regardless of which option you chose above, you will now see the dialog shown in figure 1.13.

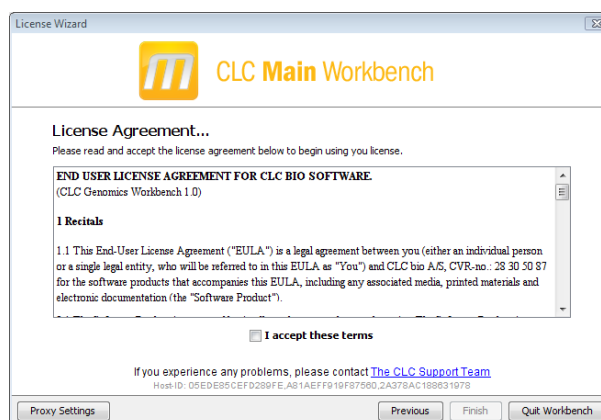

Figure 1.13: Read the license agreement carefully.

Please read the License agreement carefully before clicking **I accept these terms** and **Finish**.

1.4.4 Upgrade license

If you already have used a previous version of *CLC Main Workbench*, and you are entitled to upgrading to the new *CLC Main Workbench 6.8*, select this option to get a license upgrade.

When you click **Next**, the workbench will search for a previous installation of *CLC Main Workbench*. It will then locate the old license.

If the Workbench succeeds to find an existing license, the next dialog will look as shown in figure 1.14.

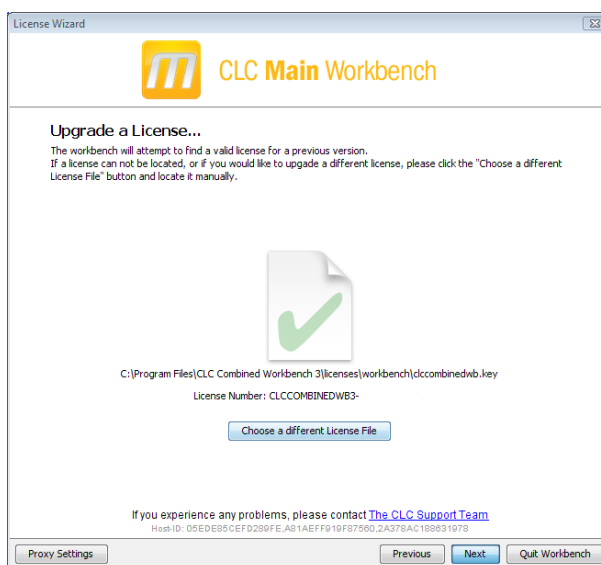

Figure 1.14: An old license is detected.

When you click **Next**, the Workbench checks on CLC bio's web server to see if you are entitled to upgrade your license.

Note! If you should be entitled to get an upgrade, and you do not get one automatically in this process, please contact support@clcbio.com.

In this dialog, there are two options:

- **Direct download.** The workbench will attempt to contact the online CLC Licenses Service, and download the license directly. This method requires internet access from the workbench.
- **Go to license download web page.** The workbench will open a Web Browser with the License Download web page when you click **Next**. From there you will be able to download your license as a file and import it. This option allows you to get a license, even though the Workbench does not have direct access to the CLC Licenses Service.

If you select the first option, and it turns out that you do not have internet access from the Workbench (because of a firewall, proxy server etc.), you will be able to click **Previous** and use the other option instead.

Direct download

Selecting the first option takes you to the dialog shown in figure 1.15.

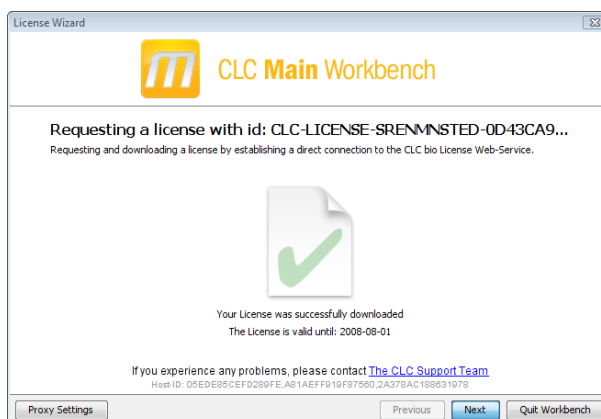

Figure 1.15: A license has been downloaded.

A progress for getting the license is shown, and when the license is downloaded, you will be able to click **Next**.

Go to license download web page

Selecting the second option, *Go to license download web page*, opens the license web page as shown in 1.16.

Figure 1.16: The license web page where you can download a license.

Click the **Request Evaluation License** button, and you will be able to save the license on your computer, e.g. on the Desktop.

Back in the Workbench window, you will now see the dialog shown in 1.17.

Click the **Choose License File** button and browse to find the license file you saved before (e.g. on your Desktop). When you have selected the file, click **Next**.

Accepting the license agreement

Regardless of which option you chose above, you will now see the dialog shown in figure 1.18.

Please read the License agreement carefully before clicking **I accept these terms** and **Finish**.

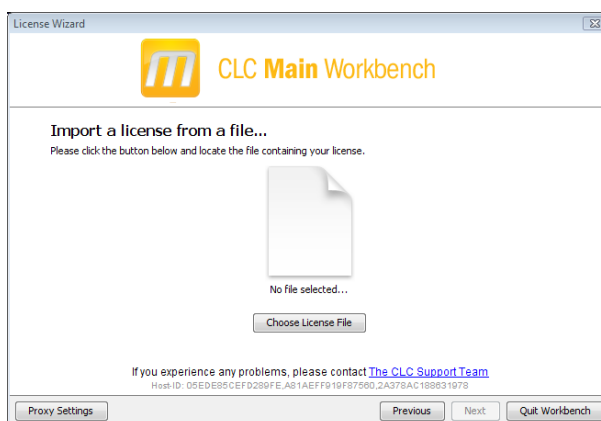

Figure 1.17: Importing the license downloaded from the web site.

Figure 1.18: Read the license agreement carefully.

1.4.5 Configure license server connection

If your organization has installed a license server, you can use a floating license. The license server has a set of licenses that can be used on all computers on the network. If the server has e.g. 10 licenses, it means that maximum 10 computers can use a license *simultaneously*. When you have selected this option and click **Next**, you will see the dialog shown in figure 1.19.

This dialog lets you specify how to connect to the license server:

- **Connect to a license server.** Check this option if you wish to use the license server.
- **Automatically detect license server.** By checking this option you do not have to enter more information to connect to the server.
- **Manually specify license server.** There can be technical limitations which mean that the license server cannot be detected automatically, and in this case you need to specify more options manually:
 - **Host name.** Enter the address for the licenser server.
 - **Port.** Specify which port to use.
- **Disable license borrowing on this computer.** If you do not want users of the computer to borrow a license (see section 1.4.5), you can check this option.

Figure 1.19: Connecting to a license server.

Borrow a license

A floating license can only be used when you are connected to the license server. If you wish to use the *CLC Main Workbench* when you are not connected to the server, you can *borrow* a license. Borrowing a license means that you take one of the floating licenses available on the server and borrow it for a specified amount of time. During this time period, there will be one less floating license available on the server.

At the point where you wish to borrow a license, you have to be connected to the license server. The procedure for borrowing is this:

1. Click **Help | License Manager** to display the dialog shown in figure 1.22.
2. Use the checkboxes to select the license(s) that you wish to borrow.
3. Select how long time you wish to borrow the license, and click **Borrow Licenses**.
4. You can now go offline and work with *CLC Main Workbench*.
5. When the borrow time period has elapsed, you have to connect to the license server again to use *CLC Main Workbench*.
6. When the borrow time period has elapsed, the license server will make the floating license available for other users.

Note that the time period is not the period of time that you actually use the Workbench.

Note! When your organization's license server is installed, license borrowing can be turned off. In that case, you will not be able to borrow licenses.

No license available...

If all the licenses on the server are in use, you will see a dialog as shown in figure 1.20 when you start the Workbench.

Figure 1.20: No more licenses available on the server.

In this case, please contact your organization's license server administrator. To purchase additional licenses, contact sales@clcbio.com.

You can also click the **Limited Mode** button (see section 1.4.6).

If your connection to the license server is lost, you will see a dialog as shown in figure 1.21.

Figure 1.21: Unable to contact license server.

In this case, you need to make sure that you have access to the license server, and that the server is running. However, there may be situations where you wish to use another license, or see information about the license you currently use. In this case, open the license manager:

Help | License Manager (📄)

The license manager is shown in figure 1.22.

Besides letting you borrow licenses (see section 1.4.5), this dialog can be used to:

- See information about the license (e.g. what kind of license, when it expires)
- Configure how to connect to a license server (**Configure License Server** the button at the lower left corner). Clicking this button will display a dialog similar to figure 1.19.
- Upgrade from an evaluation license by clicking the **Upgrade license** button. This will display the dialog shown in figure 1.1.

Figure 1.22: The license manager.

If you wish to switch away from using a floating license, click **Configure License Server** and choose not to connect to a license server in the dialog. When you restart *CLC Main Workbench*, you will be asked for a license as described in section 1.4.

1.4.6 Limited mode

We have created the limited mode to prevent a situation where you are unable to access your data because you do not have a license. When you run in limited mode, a lot of the tools in the Workbench are not available, but you still have access to your data (also when stored in a *CLC Bioinformatics Database*). When running in limited mode, the functionality is equivalent to the *CLC Sequence Viewer* (see section A).

To get out of the limited mode and run the Workbench normally, restart the Workbench. When you restart the Workbench will try to find a proper license and if it does, it will start up normally. If it can't find a license, you will again have the option of running in limited mode.

1.5 About CLC Workbenches

In November 2005 CLC bio released two Workbenches: *CLC Free Workbench* and *CLC Protein Workbench*. *CLC Protein Workbench* is developed from the free version, giving it the well-tested user friendliness and look & feel. However, the *CLC Protein Workbench* includes a range of more advanced analyses.

In March 2006, *CLC DNA Workbench* (formerly *CLC Gene Workbench*) and *CLC Main Workbench* were added to the product portfolio of CLC bio. Like *CLC Protein Workbench*, *CLC DNA Workbench* builds on *CLC Free Workbench*. It shares some of the advanced product features of *CLC Protein Workbench*, and it has additional advanced features. *CLC Main Workbench* holds all basic and advanced features of the *CLC Workbenches*.

In June 2007, *CLC RNA Workbench* was released as a sister product of *CLC Protein Workbench*

and *CLC DNA Workbench*. *CLC Main Workbench* now also includes all the features of *CLC RNA Workbench*.

In March 2008, the *CLC Free Workbench* changed name to *CLC Sequence Viewer*.

In June 2008, the first version of the *CLC Genomics Workbench* was released due to an extraordinary demand for software capable of handling sequencing data from the new high-throughput sequencing systems like 454, Illumina Genome Analyzer and SOLiD.

For an overview of which features all the applications include, see <http://www.clcbio.com/features>.

In December 2006, CLC bio released a **Software Developer Kit** which makes it possible for anybody with a knowledge of programming in Java to develop plug-ins. The plug-ins are fully integrated with the CLC Workbenches and the Viewer and provide an easy way to customize and extend their functionalities.

In April 2012, *CLC Protein Workbench*, *CLC DNA Workbench* and *CLC RNA Workbench* were discontinued, and all customers with an valid license were offered to upgrade to *CLC Main Workbench*.

All our software will be improved continuously. If you are interested in receiving news about updates, you should register your e-mail and contact data on <http://www.clcbio.com>, if you haven't already registered when you downloaded the program.

1.5.1 New program feature request

The CLC team is continuously improving the *CLC Main Workbench* with our users' interests in mind. Therefore, we welcome all requests and feedback from users as well as suggestions for new features or more general improvements to the program on support@clcbio.com.

1.5.2 Getting help

If you encounter a problem or need help understanding how the *CLC Main Workbench* works, you can contact our customer support:

Help | Contact Support

This will open a dialog to enter your contact information and a text field for entering the question or problem you have.

You can also attach some data if that can be used to explain the problem.

When you send the support request, it will include some technical information about your installation that can be useful for answering your question. Our support staff will contact you by email shortly (learn more about our support services at <http://www.clcbio.com/support/>).

Start in safe mode

If the program becomes unstable on start-up, you can start it in **Safe mode**. This is done by pressing and holding down the Shift button while the program starts.

When starting in safe mode, the user settings (e.g. the settings in the **Side Panel**) are deleted

and cannot be restored. Your data stored in the **Navigation Area** is not deleted. When started in safe mode, some of the functionalities are missing, and you will have to restart the *CLC Main Workbench* again (without pressing Shift).

1.5.3 CLC Sequence Viewer vs. Workbenches

The advanced analyses of the commercial workbenches, *CLC Genomics Workbench* and *CLC Main Workbench* are not present in *CLC Sequence Viewer*. Likewise, some advanced analyses are available in *CLC Genomics Workbench* but not in *CLC Main Workbench*. All types of basic and advanced analyses are available in *CLC Genomics Workbench*.

However, the output of the commercial workbenches can be viewed in all other workbenches. This allows you to share the result of your advanced analyses from e.g. *CLC Main Workbench*, with people working with e.g. *CLC Sequence Viewer*. They will be able to view the results of your analyses, but not redo the analyses.

The CLC Workbenches and the *CLC Sequence Viewer* are developed for Windows, Mac and Linux platforms. Data can be exported/imported between the different platforms in the same easy way as when exporting/importing between two computers with e.g. Windows.

1.6 When the program is installed: Getting started

CLC Main Workbench includes an extensive **Help** function, which can be found in the **Help** menu of the program's **Menu bar**. The **Help** can also be shown by pressing F1. The help topics are sorted in a table of contents and the topics can be searched.

Tutorials describing hands-on examples of how to use the individual tools and features of the *CLC Main Workbench* can be found at <http://www.clcbio.com/support/tutorials/>. We also recommend our **Online presentations** where a product specialist from CLC bio demonstrates our software. This is a very easy way to get started using the program. Read more about video tutorials and other online presentations here: <http://www.clcbio.tv/>.

1.6.1 Quick start

When the program opens for the first time, the background of the workspace is visible. In the background are three quick start shortcuts, which will help you getting started. These can be seen in figure 1.23.

Figure 1.23: Three available Quick start short cuts, available in the background of the workspace.

The function of the three quick start shortcuts is explained here:

- **Import data.** Opens the **Import** dialog, which you let you browse for, and import data from your file system.

- **New sequence.** Opens a dialog which allows you to enter your own sequence.
- **Read tutorials.** Opens the tutorials menu with a number of tutorials. These are also available from the **Help** menu in the **Menu bar**.

1.6.2 Import of example data

It might be easier to understand the logic of the program by trying to do simple operations on existing data. Therefore *CLC Main Workbench* includes an example data set.

When downloading *CLC Main Workbench* you are asked if you would like to import the example data set. If you accept, the data is downloaded automatically and saved in the program. If you didn't download the data, or for some other reason need to download the data again, you have two options:

You can click **Install Example Data**  in the **Help** menu of the program. This installs the data automatically. You can also go to <http://www.clcbio.com/download> and download the example data from there.

If you download the file from the website, you need to import it into the program. See chapter 7 for more about importing data.

1.7 Plug-ins

When you install *CLC Main Workbench*, it has a standard set of features. However, you can upgrade and customize the program using a variety of plug-ins.

As the range of plug-ins is continuously updated and expanded, they will not be listed here. Instead we refer to <http://www.clcbio.com/plugin-ins> for a full list of plug-ins with descriptions of their functionalities.

1.7.1 Installing plug-ins

Plug-ins are installed using the plug-in manager³:

Help in the Menu Bar | Plug-ins and Resources... 

or **Plug-ins**  **in the Toolbar**

The plug-in manager has four tabs at the top:

- **Manage Plug-ins.** This is an overview of plug-ins that are installed.
- **Download Plug-ins.** This is an overview of available plug-ins on CLC bio's server.
- **Manage Resources.** This is an overview of resources that are installed.
- **Download Resources.** This is an overview of available resources on CLC bio's server.

To install a plug-in, click the **Download Plug-ins** tab. This will display an overview of the plug-ins that are available for download and installation (see figure 1.24).

³In order to install plug-ins on Windows Vista, the Workbench must be run in administrator mode: Right-click the program shortcut and choose "Run as Administrator". Then follow the procedure described below.

Figure 1.24: The plug-ins that are available for download.

Clicking a plug-in will display additional information at the right side of the dialog. This will also display a button: **Download and Install**.

Click the plug-in and press **Download and Install**. A dialog displaying progress is now shown, and the plug-in is downloaded and installed.

If the plug-in is not shown on the server, and you have it on your computer (e.g. if you have downloaded it from our web-site), you can install it by clicking the **Install from File** button at the bottom of the dialog. This will open a dialog where you can browse for the plug-in. The plug-in file should be a file of the type ".cpa".

When you close the dialog, you will be asked whether you wish to restart the *CLC Main Workbench*. The plug-in will not be ready for use until you have restarted.

1.7.2 Uninstalling plug-ins

Plug-ins are uninstalled using the plug-in manager:

Help in the Menu Bar | Plug-ins and Resources... (📁)

or **Plug-ins** (📁) in the Toolbar

This will open the dialog shown in figure 1.25.

The installed plug-ins are shown in this dialog. To uninstall:

Click the plug-in | Uninstall

If you do not wish to completely uninstall the plug-in but you don't want it to be used next time you start the Workbench, click the **Disable** button.

When you close the dialog, you will be asked whether you wish to restart the workbench. The plug-in will not be uninstalled until the workbench is restarted.

Figure 1.25: The plug-in manager with plug-ins installed.

1.7.3 Updating plug-ins

If a new version of a plug-in is available, you will get a notification during start-up as shown in figure 1.26.

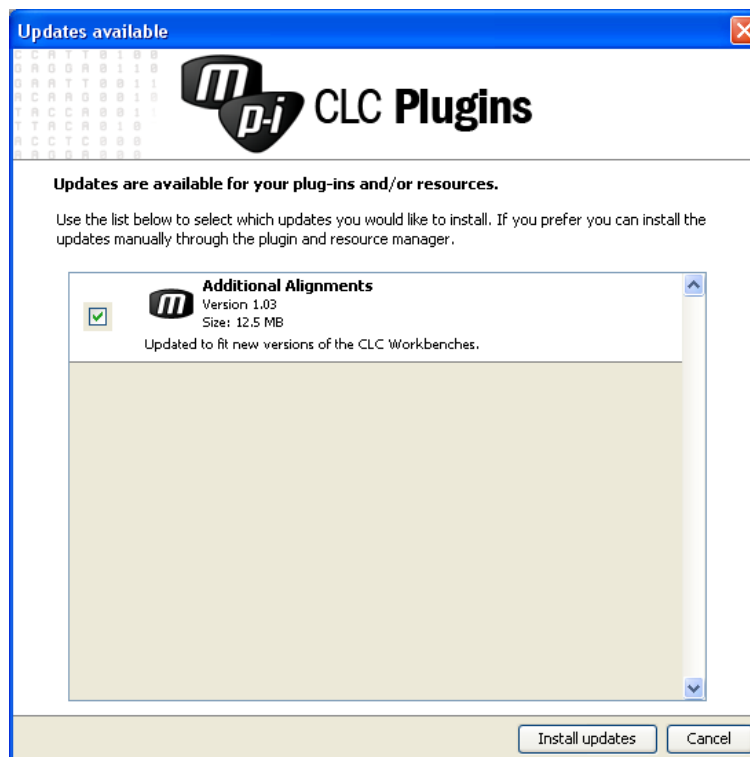

Figure 1.26: Plug-in updates.

In this list, select which plug-ins you wish to update, and click **Install Updates**. If you press

Cancel you will be able to install the plug-ins later by clicking **Check for Updates** in the Plug-in manager (see figure 1.25).

1.7.4 Resources

Resources are downloaded, installed, un-installed and updated the same way as plug-ins. Click the **Download Resources** tab at the top of the plug-in manager, and you will see a list of available resources (see figure 1.27).

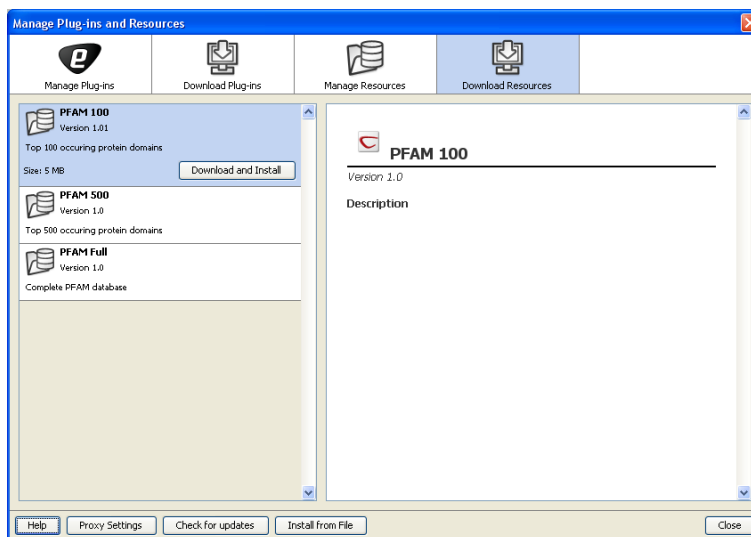

Figure 1.27: Resources available for download.

Currently, the only resources available are PFAM databases (for use with *CLC Genomics Workbench* and *CLC Main Workbench*).

Because procedures for downloading, installation, uninstallation and updating are the same as for plug-ins see section 1.7.1 and section 1.7.2 for more information.

1.8 Network configuration

If you use a proxy server to access the Internet you must configure *CLC Main Workbench* to use this. Otherwise you will not be able to perform any online activities (e.g. searching GenBank). *CLC Main Workbench* supports the use of a HTTP-proxy and an anonymous SOCKS-proxy.

To configure your proxy settings, open *CLC Main Workbench*, and go to the **Advanced**-tab of the **Preferences** dialog (figure 1.28) and enter the appropriate information. The **Preferences** dialog is opened from the **Edit** menu.

You have the choice between a HTTP-proxy and a SOCKS-proxy. *CLC Main Workbench* only supports the use of a SOCKS-proxy that does not require authorization.

You can select whether the proxy should be used also for FTP and HTTPS connections.

Exclude hosts can be used if there are some hosts that should be contacted directly and not through the proxy server. The value can be a list of hosts, each separated by a |, and in addition a wildcard character * can be used for matching. For example: *.foo.com|localhost.

Figure 1.28: Adjusting proxy preferences.

If you have any problems with these settings you should contact your systems administrator.

1.9 The format of the user manual

This user manual offers support to Windows, Mac OS X and Linux users. The software is very similar on these operating systems. In areas where differences exist, these will be described separately. However, the term "right-click" is used throughout the manual, but some Mac users may have to use Ctrl+click in order to perform a "right-click" (if they have a single-button mouse).

The most recent version of the user manuals can be downloaded from <http://www.clcbio.com/usermanuals>.

The user manual consists of four parts.

- The **first part** includes the introduction and some tutorials showing how to apply the most significant functionalities of *CLC Main Workbench*.
- The **second part** describes in detail how to operate all the program's basic functionalities.
- The **third part** digs deeper into some of the bioinformatic features of the program. In this part, you will also find our "Bioinformatics explained" sections. These sections elaborate on the algorithms and analyses of *CLC Main Workbench* and provide more general knowledge of bioinformatic concepts.
- The **fourth part** is the Appendix and Index.

Each chapter includes a short table of contents.

1.9.1 Text formats

In order to produce a clearly laid-out content in this manual, different formats are applied:

- A feature in the program is in bold starting with capital letters. (Example: **Navigation Area**)

- An explanation of how a particular function is activated, is illustrated by "|" and bold. (E.g.: **select the element | Edit | Rename**)

2.21.2 The Toolbox way of finding restriction sites	109

This chapter contains tutorials representing some of the features of *CLC Main Workbench*. The first tutorials are meant as a short introduction to operating the program. The last tutorials give examples of how to use some of the main features of *CLC Main Workbench*.  **Watch video tutorials at <http://www.clcbio.tv>.**

2.1 Tutorial: Getting Started

This brief tutorial will take you through the most basic steps of working with the CLC Workbenches. The tutorial introduces the user interface, shows how to create a folder, and demonstrates how to import your own existing data into the program. The *CLC Main Workbench* will be used to illustrate these functions.

When you open *CLC Main Workbench* for the first time, the user interface looks like figure 2.1.

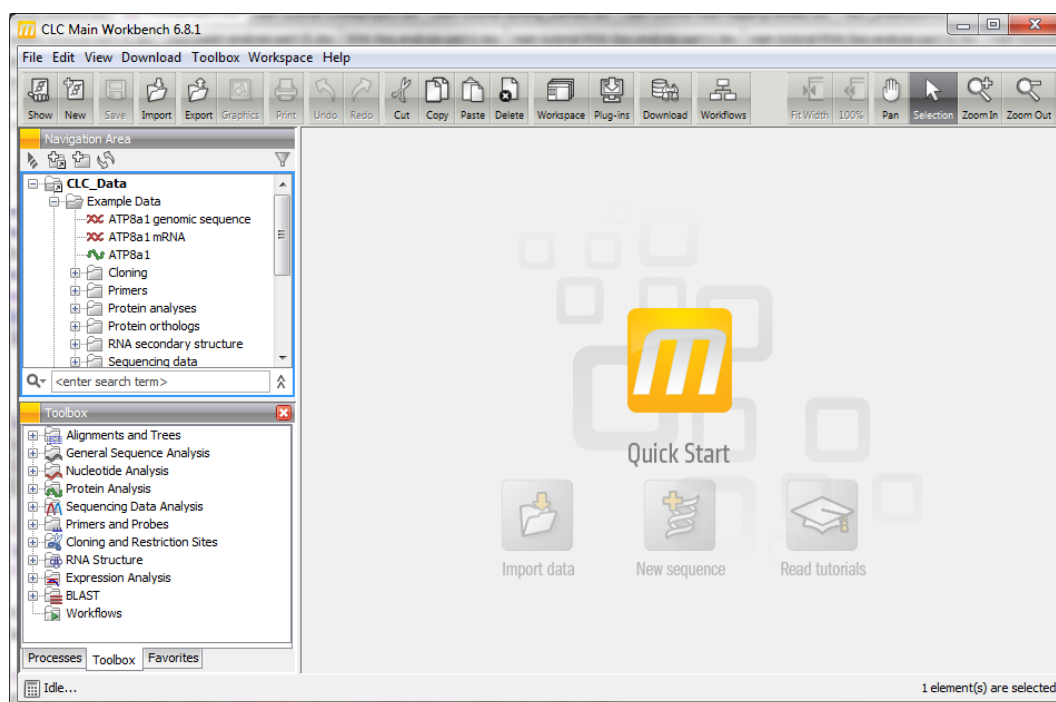

Figure 2.1: The user interface as it looks when you start the program for the first time. (Windows version of **CLC Main Workbench**. The interface is similar for Mac and Linux.)

At this stage, the important issues are the **Navigation Area** and the **View Area**.

The **Navigation Area** to the left is where you keep all your data for use in the program. Most analyses of *CLC Main Workbench* require that the data is saved in the **Navigation Area**. There

are several ways to get data into the **Navigation Area**, and this tutorial describes how to import existing data.

The **View Area** is the main area to the right. This is where the data can be 'viewed'. In general, a **View** is a display of a piece of data, and the **View Area** can include several **Views**. The **Views** are represented by tabs, and can be organized e.g. by using 'drag and drop'.

2.1.1 Creating a a folder

When *CLC Main Workbench* is started there is one element in the **Navigation Area** called **CLC_Data**¹. This element is a **Location**. A location points to a folder on your computer where your data for use with *CLC Main Workbench* is stored.

The data in the location can be organized into folders. Create a folder:

File | New | Folder (📁)
or **Ctrl + Shift + N** (⌘ + Shift + N on Mac)

Name the folder 'My folder' and press **Enter**.

2.1.2 Import data

Next, we want to import a sequence called NC_010473.gbk (GenBank format). Data can be downloaded from <http://www.clcbio.com/downloads> under "EXAMPLE DATA", Roche/454 pyrosequencing genome data from *E. coli* commensal strain K-12. (This file is chosen for demonstration purposes only - you may have another file on your desktop, which you can use to follow this tutorial. You can import all kinds of files.)

In order to import the NC_010473.gbk file:

Select 'My folder' | Import (📁) **in the Toolbar | navigate to NC_010473.gbk file where you have saved it | Select**

The sequence is imported into the folder that was selected in the **Navigation Area**, before you clicked **Import**. Double-click the sequence in the **Navigation Area** to view it. The final result looks like figure 2.2.

2.2 Tutorial: View Sequence

This brief tutorial will take you through some different ways to display a sequence in the program. The tutorial introduces zooming on a sequence, dragging tabs, and opening selection in new view.

We will be working with the sequence called *pcDNA3-atp8a1* located in the 'Cloning' folder in the Example data. Double-click the sequence in the **Navigation Area** to open it. The sequence is displayed with annotations above it. (See figure 2.3).

As default, *CLC Main Workbench* displays a sequence with annotations (colored arrows on the sequence like the green promoter region annotation in figure 2.3) and zoomed to see the residues.

¹If you have downloaded the example data, this will be placed as a folder in *CLC_Data*

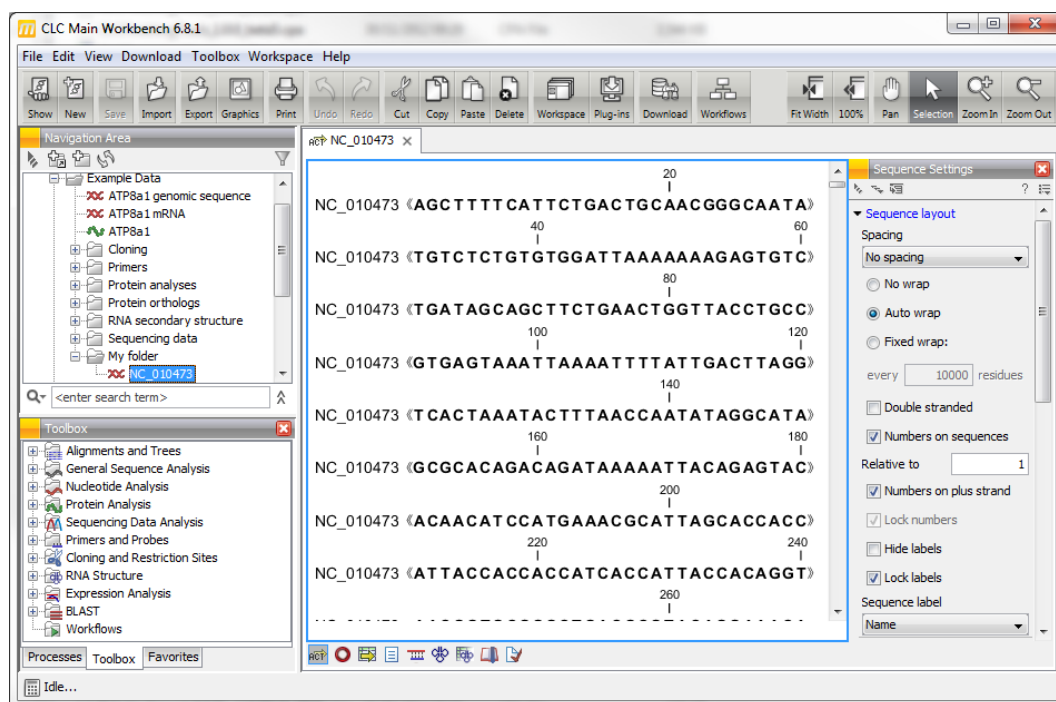

Figure 2.2: The NC_010473 file is imported and opened.

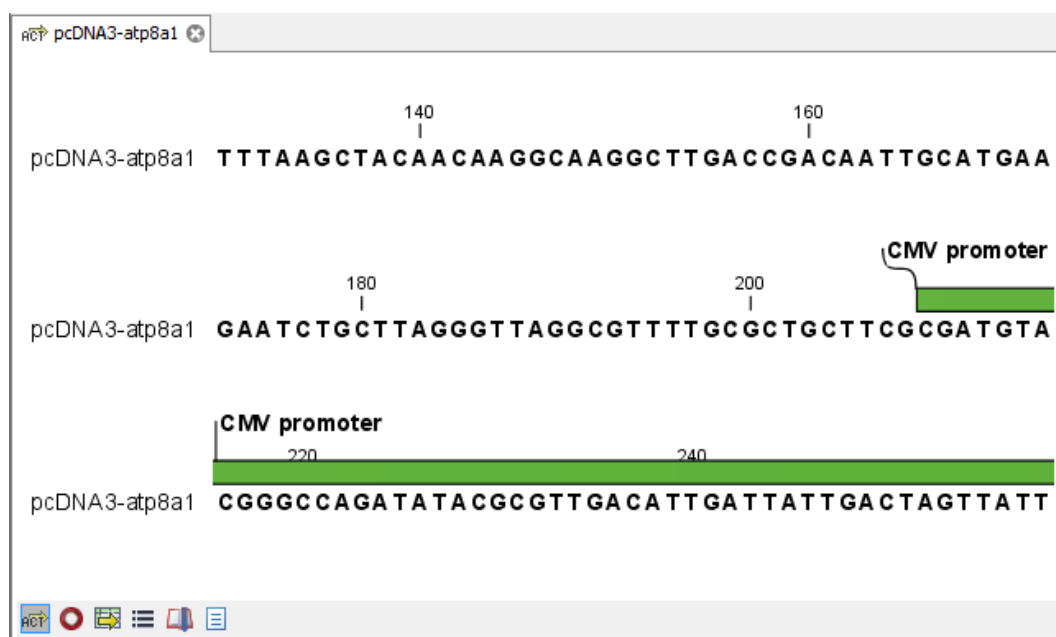

Figure 2.3: Sequence pcDNA3-atp8a1 opened in a view.

In this tutorial we want to have an overview of the whole sequence. Hence;

click Zoom Out (🔍) in the Toolbar | click the sequence until you can see the whole sequence

This sequence is circular, which is indicated by << and >> at the beginning and the end of the sequence.

In the following we will show how the same sequence can be displayed in two different views - one linear view and one circular view. First, zoom in to see the residues again by using the **Zoom**

In  or the **100%** . Then we make a split view by:

press and hold the Ctrl-button on the keyboard (⌘ on Mac) | click Show as Circular  at the bottom of the view

This opens an additional view of the vector with a circular display, as can be seen in figure 2.4.

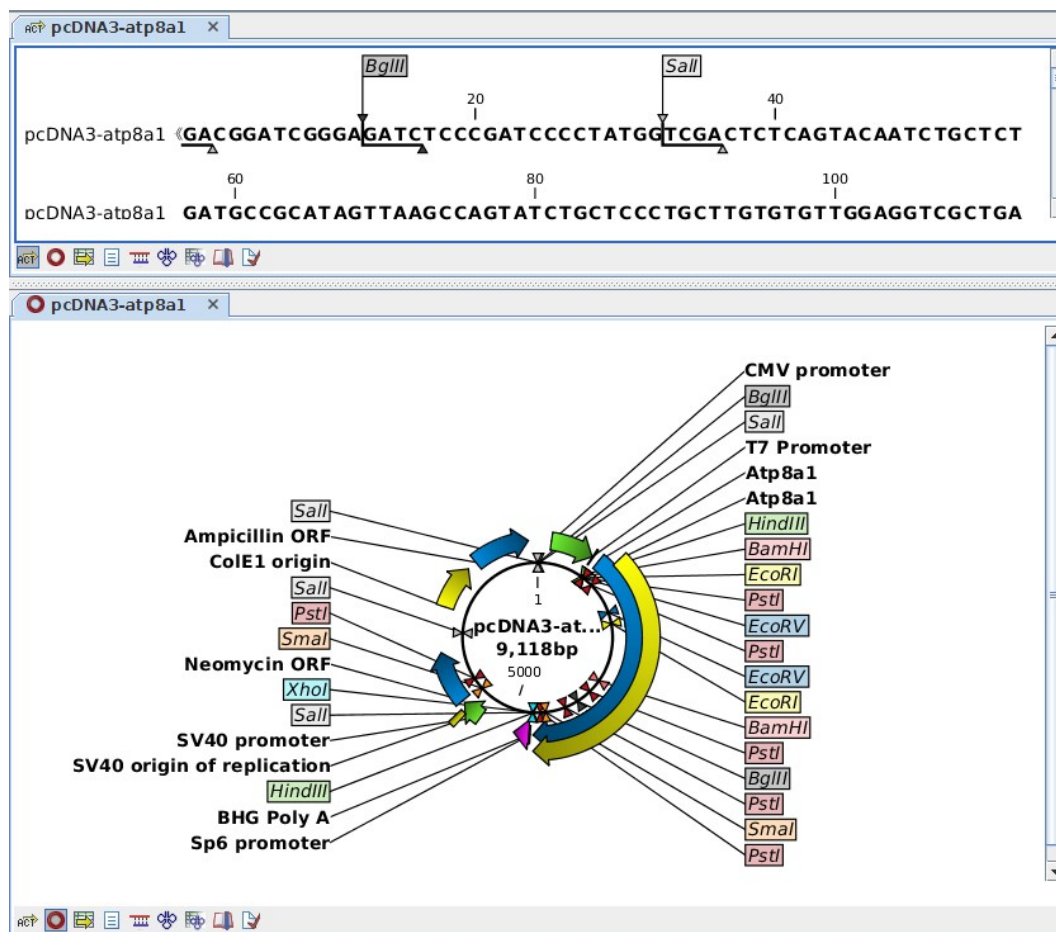

Figure 2.4: The resulting two views which are split horizontally.

Make a selection on the circular sequence (remember to switch to the **Selection**  tool in the tool bar) and note that this selection is also reflected in the linear view above.

2.3 Tutorial: Side Panel Settings

This brief tutorial will show you how to use the **Side Panel** to change the way your sequences, alignments and other data are shown. You will also see how to save the changes that you made in the **Side Panel**.

Open the protein alignment located under *Protein orthologs* in the **Example data**. The initial view of the alignment has colored the residues according to the Rasmol color scheme, and the alignment is automatically wrapped to fit the width of the view (shown in figure 2.5).

Now, we are going to modify how this alignment is displayed. For this, we use the settings in the **Side Panel** to the right. All the settings are organized into groups, which can be expanded

Figure 2.5: The protein alignment as it looks when you open it with background color according to the Rasmol color scheme and automatically wrapped.

/ collapsed by clicking the name of the group. The first group is **Sequence Layout** which is expanded by default.

First, select **No wrap** in the **Sequence Layout**. This means that each sequence in the alignment is kept on the same line. To see more of the alignment, you now have to scroll horizontally.

Next, expand the **Annotation Layout** group and select **Show Annotations**. Set the **Offset** to "More offset" and set the **Label** to "Stacked".

Expand the **Annotation Types** group. Here you will see a list of the types annotation that are carried by the sequences in the alignment (see figure 2.6).

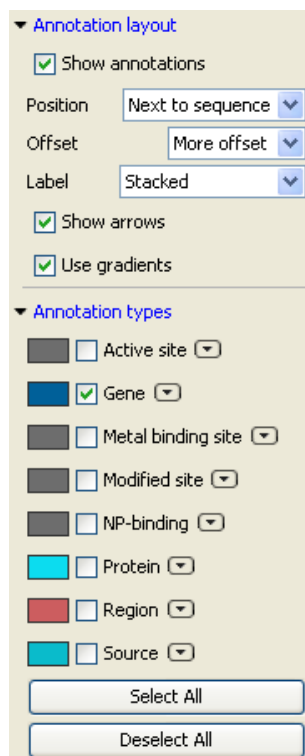

Figure 2.6: The Annotation Layout and the Annotation Types in the Side Panel.

Check the "Region" annotation type, and you will see the regions as red annotations on the sequences.

Next, we will change the way the residues are colored. Click the **Alignment Info** group and under **Conservation**, check "Background color". This will use a gradient as background color for the residues. You can adjust the coloring by dragging the small arrows above the color box.

2.3.1 Saving the settings in the Side Panel

Now the alignment should look similar to figure 2.7.

Figure 2.7: The alignment when all the above settings have been changed.

At this point, if you just close the view, the changes made to the **Side Panel** will not be saved. This means that you would have to perform the changes again next time you open the alignment. To save the changes to the **Side Panel**, click the **Save/Restore Settings** button (⚙️) at the top of the **Side Panel** and click **Save Settings** (see figure 2.8).

Figure 2.8: Saving the settings of the Side Panel.

This will open the dialog shown in figure 2.9.

Figure 2.9: Dialog for saving the settings of the Side Panel.

In this way you can save the current state of the settings in the **Side Panel** so that you can apply

them to alignments later on. If you check **Always apply these settings**, these settings will be applied every time you open a view of the alignment.

Type "My settings" in the dialog and click **Save**.

2.3.2 Applying saved settings

When you click the **Save/Restore Settings** button (☰) again and select **Apply Saved Settings**, you will see "My settings" in the menu together with some pre-defined settings that the *CLC Main Workbench* has created for you (see figure 2.10).

Figure 2.10: Menu for applying saved settings.

Whenever you open an alignment, you will be able to apply these settings. Each kind of view has its own list of settings that can be applied.

At the bottom of the list you will see the "CLC Standard Settings" which are the default settings for the view.

2.4 Tutorial: GenBank Search and Download

The workbench allows you to search the NCBI GenBank database directly from the program, giving you the opportunity to both open, view, analyze and save the search results without using any other applications. To conduct a search in NCBI GenBank from the workbench you must be connected to the Internet.

This tutorial shows how to find a complete human hemoglobin DNA sequence in a situation where you do not know the accession number of the sequence.

To start the search:

Download | Search for Sequences at NCBI (🌐)

This opens the search view. We are searching for a DNA sequence, hence:

Nucleotide

Now we are going to adjust parameters for the search. By clicking **Add search parameters** you activate an additional set of fields where you can enter search criteria. Each search criterion consists of a drop down menu and a text field. In the drop down menu you choose which part of the NCBI database to search, and in the text field you enter what to search for:

Click Add search parameters until three search criteria are available | choose Organism in the first drop down menu | write 'human' in the adjoining text field | choose All Fields in the second drop down menu | write 'hemoglobin' in the adjoining text field | choose All Fields in the third drop down menu | write 'complete' in the adjoining text field

The screenshot shows the NCBI search interface. At the top, there are radio buttons for 'Nucleotide' (selected) and 'Protein'. Below this, there are three search criteria added, each with a dropdown menu set to 'All Fields' and a text input field. The first criterion is 'human', the second is 'hemoglobin', and the third is 'complete'. There are 'Add search parameters' and 'Start search' buttons. Below the search area, there is a 'Filter:' field and a 'Rows: 50' indicator. The main area displays a table of search results with columns for 'Accession', 'Definition', and 'Modification Date'. The table lists several entries, including 'Aspergillus niger contig AN08c0110, complete genome' and 'Homo sapiens hemoglobin, gamma G, mRNA (cDNA clone)'. At the bottom, there are buttons for 'Download and Open', 'Download and Save', and 'Open at NCBI'. A 'Total number of hits: 215' is shown with a 'more...' link.

Accession	Definition	Modification Date

Figure 2.11: NCBI search view.

Click **Start search** (🔍) to commence the search in NCBI.

2.4.1 Searching for matching objects

When the search is complete, the list of hits is shown. If the desired complete human hemoglobin DNA sequence is found, the sequence can be viewed by double-clicking it in the list of hits from the search. If the desired sequence is not shown, you can click the 'More' button below the list to see more hits.

2.4.2 Saving the sequence

The sequences which are found during the search can be displayed by double-clicking in the list of hits. However, this does not save the sequence. You can save one or more sequence by selecting them and:

click Download and Save

or **drag the sequences into the Navigation Area**

2.5 Tutorial: Microarray-Based Expression Analysis Part I: Getting Started

This tutorial is the first part of a series of tutorials about expression analysis. Expression analysis often requires advanced skills in statistics, but this tutorial is intended to show a straight-forward example of how to identify and interpret the differentially expressed genes in samples from two different tissues. If you are familiar with the statistical concepts and issues within expression

analysis, you may find this tutorial too simplistic, but we have favored a simple and quick introduction over an exhaustive and more "correct" explanation.

The data comes from a study of gene expression in tissues from cardiac left ventricle and diaphragm muscle of rats [van Lunteren et al., 2008]. During this series of tutorials, you will see how to import and set up the data in an experiment with two groups (part I), to perform quality checks on the data (part II), to perform statistics and clustering to identify and visualize differentially expressed genes (part III), and finally to use annotations to categorize and interpret patterns among the differentially expressed genes in a biological context (part IV).

2.5.1 Importing array data

First, import the data set which can be downloaded from the Gene Expression Omnibus (GEO) database at NCBI: <http://www.ncbi.nlm.nih.gov/geo/query/acc.cgi?acc=GSE6943&targ=gsm&form=text&view=data>. After download, click **Import** (📁) in the Tool bar and select the file. You will now have 12 arrays in your **Navigation Area** as shown in figure 2.12.

Figure 2.12: 12 microarrays have been imported.

2.5.2 Grouping the samples

The next step is to tell the *CLC Main Workbench* how the 12 samples are related.

This is done by setting up an **Experiment** (📁). An **Experiment** is the central data type when analyzing expression data in the *CLC Main Workbench*. It includes a set of samples and information about how the samples are related (which groups they belong to). The **Experiment** is also used to accumulate calculations like t-tests and clustering.

First step is to set up the experiment:

Toolbox | Transcriptomics Analysis (📁) | Set Up Experiment (📁)

Select the 12 arrays that you have imported (see figure 2.13).

Note that we use "samples" as the general term for both microarray-based expression values and sequencing-based expression values. Clicking **Next** shows the dialog in figure 2.14.

Here you define the number of groups in the experiment. Since we compare heart tissue with

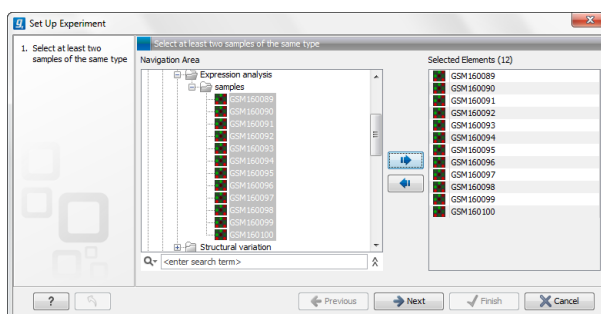

Figure 2.13: Select the 12 microarrays that have been imported.

Figure 2.14: Defining the number of groups.

diaphragm tissue, we use a two-group comparison. Leave it as **Unpaired**. Clicking **Next** shows the dialog in figure 2.15.

Figure 2.15: Naming the groups.

Name the first group **Heart** and the second group **Diaphragm** and click **Next** (see figure 2.16).

Here you see a list of all the samples you chose in figure 2.13. Now select the first 6 samples (by clicking in the group column of the first sample and while holding down the mouse button you drag and select the other five samples), right-click and select **Heart**. Select the last 6 samples, right-click and select **Diaphragm**. In this way you define which group each sample belongs to.

Click **Finish** and the experiment will be created. Note that the information from samples located in the **Navigation Area** is copied into the experiment, so they now exist independently of each other.

Figure 2.16: Assigning the samples to groups.

2.5.3 The experiment table

Once it is created, the experiment will be opened in a table as shown in figure 2.17.

Feature ID	Experiment					GSM160089		GSM160090	
	Total prese...	Range (orig...	IQR (origin...	Difference (...	Fold Chang...	Expression ...	Presence call	Expression ...	Presence call
1367452_at	12	862,00	470,50	464,82	1,19	2.532,90 P		2.518,60 P

1367461_at	12	485,70	280,20	184,35	1,29	507,00 P		610,30 P	
1367462_at	12	1.032,50	309,70	268,23	1,08	3.207,50 P		3.371,30 P	
1367463_at	12	1.621,60	510,00	701,97	1,21	3.510,30 P		3.050,30 P	
1367464_at	12	317,70	202,00	-111,67	-1,13	797,70 P		1.038,90 P	
1367465_at	12	699,00	196,80	257,50	1,22	1.103,10 P		1.281,80 P	
1367466_at	12	265,50	122,50	-54,67	-1,04	1.385,10 P		1.321,30 P	
1367467_at	12	1.780,60	453,40	414,95	1,12	3.561,60 P		3.838,40 P	
1367468_at	12	572,60	480,60	439,67	1,73	656,30 P		658,20 P	
1367469_at	12	1.726,80	664,10	-317,50	-1,07	5.676,30 P		5.730,20 P	

Figure 2.17: The experiment table.

The table includes the expression values for each sample and in addition a few extra values have been calculated such as the range, the IQR (Interquartile Range), fold change and difference values and the present counts for the whole experiment and the individual groups (note that absent/present calls are not available on all kinds of data).

Save the experiment and you are ready to proceed to the expression analysis tutorial part II.

2.6 Tutorial: Microarray-Based Expression Analysis Part II: Quality Control

This tutorial is the second part of a series of tutorials about expression analysis. We continue working with the data set introduced in the first tutorial.

In this tutorial we will examine various methods to perform quality control of the data.

2.6.1 Transformation

First we inspect to what extent the variance in expression values depends on the mean. For this we create an **MA Plot**:

Toolbox | Transcriptomics Analysis (📁) | **General Plots | Create MA Plot** (📊)

Since the MA plot compares two samples, we will start out selecting two of the 12 arrays and click **Finish**. This will show a plot similar to the one shown in figure 2.18.

Figure 2.18: MA plot before transformation.

The X axis shows the mean expression level of a feature on the two arrays and the Y axis shows the difference in expression levels for a feature on the two arrays. From the plot shown in figure 2.18 it is clear that the variance increases with the mean. To remove some of the dependency, we want to **transform** the data:

Toolbox | Transcriptomics Analysis (📁) | **Transformation and Normalization | Transform** (📈)

Select the same two arrays as used for the plot, click **Next**, choose **Log 2** transformation and click **Finish**. Now create an MA plot again as described above, but when you click **Next** you can see that you now also have the option to choose **Transformed expression values** (see figure 2.19).

Figure 2.19: Select the transformed expression values.

Select the transformed values. You will see that these three selection boxes; Original, Transformed and Normalized expression values are used several places when expression values are used in a calculation.

Click **Finish**.

This will result in a quite different plot as shown in figure 2.20.

The much more symmetric and even spread indicates that the dependence of the variance on the mean is not as strong as it was before transformation.

Figure 2.20: MA plot after transformation.

We have now only transformed the values of the two samples used for the MA plot. Hence, we need to transform the expression values within the entire experiment, as we will use the transformed data in the further analysis. To transform the entire experiment:

Toolbox | Transcriptomics Analysis (🇧🇷) | Transformation and Normalization | Transform (📈)

Select the experiment created in the first part of this tutorial series, click **Next**, choose **Log 2** transformation and click **Finish**.

If you open the table, you will see that all the samples have an extra column with transformed expression values (figure 2.21).

Feature ID	Experiment			GSM160089		GSM160090	
	Total prese...	IQR - Expre...	IQR - Trans...	Expression ...	Presence call	Expression ...	Presence call
1367452_at	12	470,50	0,08	2.532,90 P	3,40	2.518,60 P	
1367453_at	12	430,80	0,05	3.464,20 P	3,54	3.197,40 P	
1367454_at	12	349,10	0,09	1.620,80 P	3,21	1.870,50 P	
1367455_at	12	1.352,90	0,12	5.512,50 P	3,74	4.103,90 P	
1367456_at	12	1.264,20	0,11	6.090,80 P	3,78	5.352,20 P	
1367457_at	12	319,00	0,15	1.093,90 P	3,04	1.134,30 P	
1367458_at	12	148,90	0,19	347,80 P	2,54	223,90 P	
1367459_at	12	2.434,30	0,12	7.665,80 P	3,88	7.415,90 P	
1367460_at	12	557,00	0,08	3.155,70 P	3,50	2.946,90 P	
1367461_at	12	280,20	0,16	507,00 P	2,71	610,30 P	
1367462_at	12	309,70	0,04	3.207,50 P	3,51	3.371,30 P	
1367463_at	12	510,00	0,06	3.510,30 P	3,55	3.050,30 P	
1367464_at	12	202,00	0,10	797,70 P	2,90	1.038,90 P	

Figure 2.21: Transformed expression values have been added to the table.

There is also an extra column for transformed group means and transformed IQR.

2.6.2 Comparing spread and distribution

In order to perform meaningful statistical analysis and inferences from the data, you need to ensure that the samples are comparable. Systematic differences between the samples that are

likely to be due to noise (e.g. differences in sample preparation and processing) rather than true biological variability should be removed. To examine and compare the overall distribution of the transformed expression values in the samples you may use a **Box plot** (📊):

Toolbox | Transcriptomics Analysis (📁) | Quality Control | Create Box Plot (📊)

Select the experiment and click **Next**. Choose the **Transformed expression values** and **Finish**.

The box plot is shown in figure 2.22.

Figure 2.22: A box plot of the 12 samples in the experiment, colored by group.

This plot looks very good because none of the samples stands out from the rest. If you compare this plot to the one shown in figure 2.23 from another data set, you can see the difference.

Figure 2.23: A box plot showing one sample that stands out from the rest.

The second sample from the left has a distribution that is quite different from the others. If you have a data set like this, then you should consider removing the bad quality sample.

2.6.3 Group differentiation

The next step in the quality control is to check whether the overall variability of the samples reflect their grouping. In other words we want the replicates to be relatively homogenous and

distinguishable from the samples of the other group.

First, we perform a **Principal Component Analysis (PCA)**:

Toolbox | Transcriptomics Analysis (🇺🇸) | **Quality Control | Principal Component Analysis** (📊)

Select the experiment and click **Next. Finish**. This will create a PCA plot as shown in figure 2.24).

Figure 2.24: A principal component analysis colored by group.

The plot shows the projection of the samples onto the two-dimensional space spanned by the first and second principal component. (These are the orthogonal directions in which the data exhibits the largest and second-largest variability).

The dots are colored according to the groups, and they also group very nicely in the plot. There is only one outlier - to see which sample it is, place the mouse cursor on the dot for a second, and you will see that it is the *GSM160090* from the *Heart* group.

You can display this information in the plot using the settings in the **Side Panel** to the right of the view:

Dot properties | select GSM160090 in the drop-down box | Show names

In this way you can control the coloring and dot types of the different samples and groups (see figure 2.25).

In order to complement the principal component analysis, we will also do a hierarchical clustering of the samples to see if the samples cluster in the groups we expect:

Toolbox | Transcriptomics Analysis (🇺🇸) | **Quality Control | Hierarchical Clustering of Samples** (📊)

Select the experiment and click **Next**. Leave the parameters at their default and click **Finish**.

This will display a heat map showing the clustering of samples at the bottom (see figure 2.26).

Figure 2.25: Naming the outlier.

Figure 2.26: Sample clustering.

The two overall groups formed are identical to the grouping in the experiment. You can double-check by placing your mouse on the name of the sample - that will show which group it belongs to.

Since both the principal component analysis and the hierarchical clustering confirms the grouping of the samples, we have no reason to be sceptical about the quality of the samples and we conclude that the data is OK.

Note that the heat map is not a new element to be stored in the **Navigation Area** - it is just another way of looking at the experiment (note the buttons to switch between different views in figure 2.27).

Figure 2.27: Different views on an experiment.

In part III of the tutorial series we will be looking into the different views in more detail.

To summarize this part about quality control, it looks like the data have good quality, and we are now ready to proceed to the next step where we do some statistical analysis to see which genes are differentially expressed.

2.7 Tutorial: Microarray-Based Expression Analysis Part III: Differentially Expressed Genes

This tutorial is the third part of a series of tutorials about expression analysis. We continue working with the data set introduced in the first tutorial.

In this tutorial we will identify and investigate the genes that are differentially expressed.

2.7.1 Statistical analysis

First we will carry out some statistical tests that we will use to identify the genes that are differentially expressed between the two groups:

Toolbox | Transcriptomics Analysis (🇺🇸) | Statistical Analysis | On Gaussian Data (🇺🇸)

Select the experiment created in part I of the tutorials and click **Next**. Leave the parameters at the default and click **Next** again. You will now see a dialog as shown in figure 2.28.

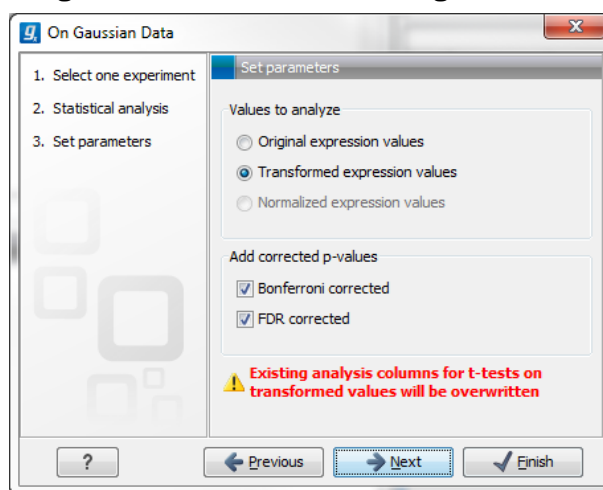

Figure 2.28: Statistical analysis.

As shown in figure 2.28 select the transformed expression values and check the two corrected p-values as well. You can read more about what they mean by clicking the **Help** (?) button in the dialog.

When you press **Finish**, a number of extra columns will be added to your experiment. For this analysis we will use the FDR p-value which is a measure that allows us to control how big a proportion of false positives (genes that we think are differentially expressed but really are not) we are willing to accept.

Click the **FDR p-value correction** column to sort it with the lowest values at the top. If you scroll down to values around $5E-4$ you can clearly see the difference between using the FDR p-value and

the Bonferroni-corrected p-value which is much stricter (p-values approaching 1 - see figure 2.29).

Figure 2.29: FDR p-values compared to Bonferroni-corrected p-values.

2.7.2 Filtering p-values

To do a more refined selection of the genes that we believe to be differentially expressed, we use the advanced filter located at the top of the experiment table. Click the **Advanced Filter** (🔍) button and you will see that the simple text-based filter is now replaced with a more advanced filter. Select **Diaphragm vs Heart transformed - FDR p-value correction** in the first drop-down box, select **<** in the next, and enter 0.0005 (or 0,0005 depending on your locale settings). Click **Apply** or press **Enter**.

This will filter the table so that only values below 0.0005 are shown (see figure 2.30).

Feature ID	Experiment										t-test: Heart vs Diaphragm transformed values

Figure 2.30: Filtering on FDR p-values.

You can see that 1471 genes fulfilled this criterion (marked with a red circle).

2.7.3 Inspecting the volcano plot

Another way of looking at this data is to click the **Volcano Plot** (🌋) at the bottom of the view. Press and hold the Ctrl key while you click (⌘ on Mac).

This will make a split view of the experiment table and the volcano plot as shown in figure 2.31.

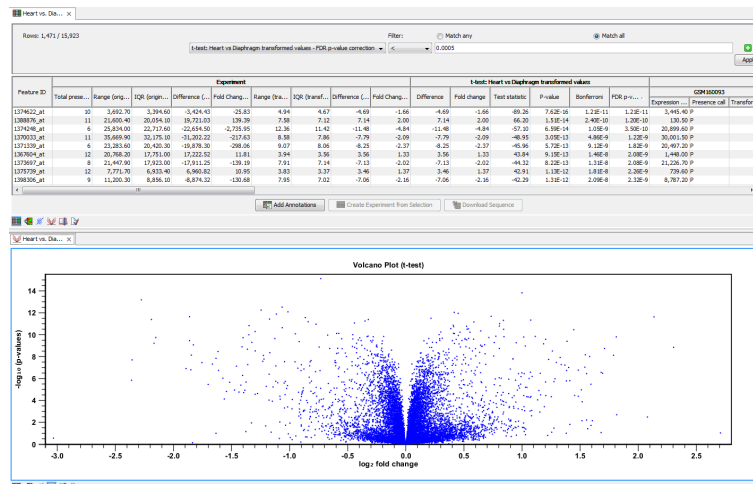

Figure 2.31: Split view of volcano plot and experiment table.

The volcano plot shows the difference between the means of the two groups on the X axis and the $-\log_{10}$ p-values on the Y axis.

If you now select the genes in the table (click in the table and press **Ctrl + A** / **⌘ + A** on Mac), you can see that the corresponding dots are selected in the volcano plot (see figure 2.32).

Figure 2.32: Volcano plot where selected dots are colored red.

2.7.4 Filtering absent/present calls and fold change

Besides filtering on low p-values, we may also take the absent/present status of the features into consideration. The absent/present status is assigned by the Affymetrix software. There can be a number of reasons why a gene is called *absent*, and sometimes it is simply because the signal is very weak. When a gene is called absent, we may not wish to include it in the list of differentially expressed genes, so we want to filter these out as well.

This can be done in several ways - in our approach we say that for any gene there must not be more than one absent call in each group. Thus, we add more criteria to the filter by clicking

the **Add search criterion** (+) button twice and enter the limit for present calls as shown in figure 2.33.

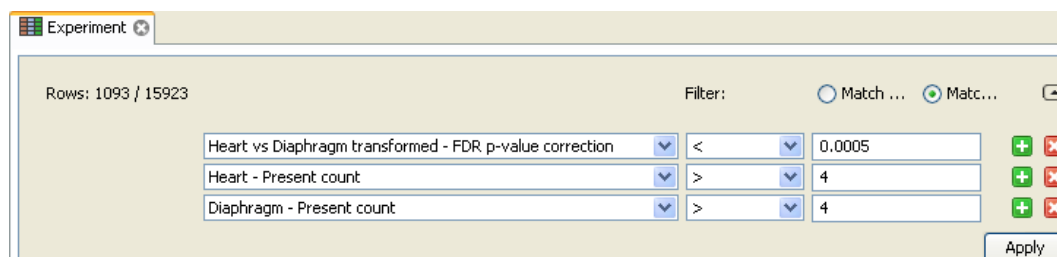

Figure 2.33: Filtering genes where at least 5 out of 6 calls in each group are present.

Before applying this filter, 1471 genes were selected, and this list is now reduced to 1093.

Often the results of microarray experiments are verified using other methods such as QPCR, and then we may want to filter out genes that exhibit differences in expression that are so small that we will not be able to verify them with another method. This is done by adding one last criterion to the filter: Difference should have an absolute value higher than 2 (as we are working with log transformed data, the group mean difference is really the *fold change*, so this filter means that we require a fold change above 2).

This final filtering is shown in figure 2.34.

Figure 2.34: The absolute value of group mean difference should be larger than 2.

Note that the **abs value >** is important because the difference could be negative as well as positive.

The result is that we end up with a list of 142 genes that are likely candidates to exhibit differential expression in the two groups.

Click one of the rows and press Ctrl + A (⌘ + A on Mac) to select the 142 genes. You can now inspect the selection in the volcano plot below as shown in figure 2.35.

2.7.5 Saving the gene list

Before we proceed to the final part of the tutorials, we save the list of genes; click **Create Experiment from Selection** (📄)

This will create a new experiment based on the selection. **Save** (💾) the new experiment next to the old one.

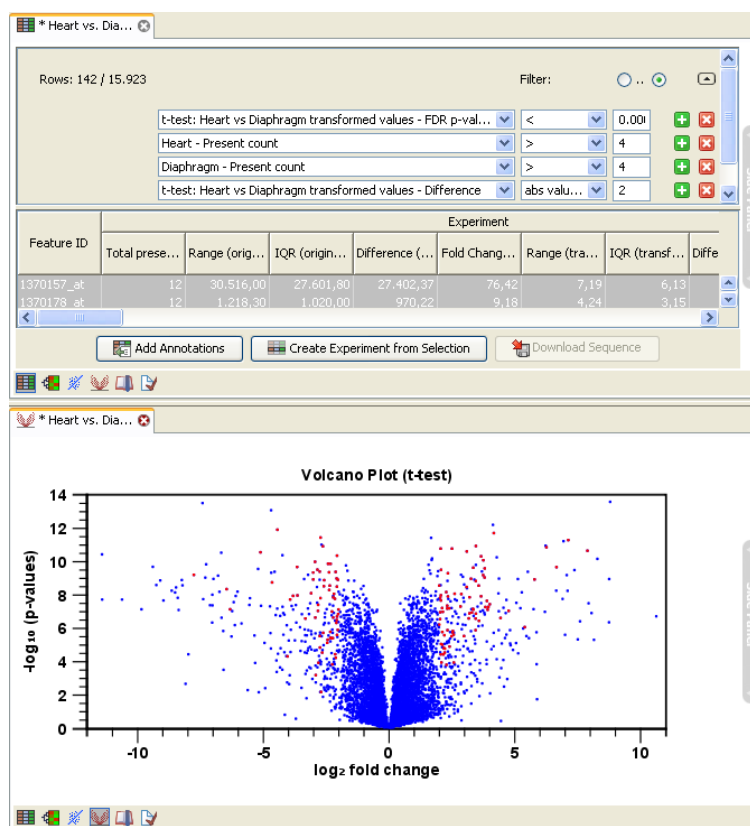

Figure 2.35: 142 genes out of 15923 selected.

2.8 Tutorial: Microarray-Based Expression Analysis Part IV: Annotation Test

This tutorial is the fourth and final part of a series of tutorials about expression analysis. We continue working with the data set introduced in the first tutorial and analyzed in part two and three.

In this tutorial we will annotate the gene list and use the annotations to see if there is a pattern in the biological annotations of the genes in the list of candidate differentially expressed genes.

We use two different methods for annotation testing: Hypergeometric Tests on Annotations and Gene Set Enrichment Analysis (GSEA).

2.8.1 Importing and adding the annotations

First step is to import an annotation file used to annotate the arrays. In this case, the data were produced using an Affymetrix chip, and the annotation file can be downloaded from the web site <http://www.affymetrix.com/support/technical/annotationfilesmain.affx>. You can access the file by search for **RAE230A**. Note that you have to sign up in order to download the file (this is a free service).

To import the annotation file, click **Import** (📁) in the Tool bar and select the file.

Next, annotate the experiment with the annotation file:

Toolbox | Transcriptomics Analysis (📁) | Annotation Test | Add Annotations (📁)

Select the experiment created in the previous tutorial and the annotation file  and click **Next** and **Finish**.

2.8.2 Inspecting the annotations

When you look in the **Side Panel** of the experiment, there are a lot of options to show and hide columns in the table. This can be done on several levels. At the **Annotation level** you find a list of all the annotations. Some are shown per default, others you will have to click to show.

An important annotation is the **Gene title** which describes the gene and is much more informative than the Feature ID.

Further down the list you find the annotation type **GO biological process**. We will use this annotation in the next two analyses.

2.8.3 Processes that are over or under represented in the small list

The first annotation test will show whether any of the GO biological processes are over-represented in our small list of 142 differentially expressed genes relate to the full set of genes measured:

Toolbox | Transcriptomics Analysis | Annotation Test | Hypergeometric Tests on Annotations

Select the two experiments (the original full experiment and the small subset of 142 genes) and click **Next**. Select **GO biological process** and **Transformed expression values** (see figure 2.36).

Figure 2.36: Testing on GO biological process.

Click **Next** and **Finish** to perform the test. The result is shown in figure 2.37.

This table lists the GO categories according to p-values for this test. If you take number 2, carbohydrate metabolic process, there are 104 genes in this category in the full set, if the subset was randomly chosen you would have expected 1 gene to be in the subset. But because there are 7 genes in this subset, this process is over-represented and given a p-value of 2.63E-5.

Category	Description	Full set	In subset	Expected i...	Observed ...	p-value
0005977	glycogen me...	19	5	0	5	3,32E-7
0005975	carbohydrat...	104	7	1	6	2,03E-5

0060048	cardiac musc...	19	3	0	3	4,55E-4
0048738	cardiac musc...	6	2	0	2	9,56E-4
0006807	nitrogen com...	8	2	0	2	1,77E-3
0051924	regulation of...	10	2	0	2	2,81E-3
0005978	glycogen bio...	11	2	0	2	3,41E-3
0002026	regulation of...	12	2	0	2	4,07E-3
0001974	blood vessel ...	16	2	0	2	7,25E-3
0002318	myeloid prog...	1	1	0	1	8,12E-3
0006603	phosphocrea...	1	1	0	1	8,12E-3
0042424	catecholamin...	1	1	0	1	8,12E-3
0031275	regulation of...	1	1	0	1	8,12E-3
0046439	L-cysteine m...	1	1	0	1	8,12E-3

Figure 2.37: The result of testing on GO biological process.

2.8.4 A different approach: Gene Set Enrichment Analysis (GSEA)

The hypergeometric tests on annotations uses a pre-defined subset of differentially expressed genes as a starting point and compares the annotations in this list to those of the genes in the full experiment. The exact limit for this subset is somewhat arbitrary - in our case we could have chosen a p-value less than 0.005 instead of 0.0005 and it would lead to a different result.

Furthermore, only the most apparently differentially expressed genes are used in the subset - one could easily imagine that other categories would be significant based on more genes with e.g. lower fold change or higher p-values.

The Gene Set Enrichment Analysis (GSEA) does not take an *a priori* defined list of differentially expressed genes and compares it to the full list - it uses a single experiment. It ranks the genes on p-value and analyzes whether there are some categories that are over-represented in the top of the list.

Toolbox | Transcriptomics Analysis (📄) | Annotation Test | Gene Set Enrichment Analysis (GSEA) (📊)

Select the original full experiment and click **Next**. In this step, make sure the **GO biological process** is chosen (see figure 2.38).

Click **Next** and select the **Transformed expression values**. Click **Finish**. The result is shown in figure 2.39.

The table is sorted on the lower tail so that the GO categories where up-regulated genes in the first group are over-represented are placed at the top, and the GO categories where up-regulated genes in the second group are over-represented are placed at the bottom.

Note that we could have chosen to filter away genes with less reliable measurements from the experiment (as shown in the previous tutorial) before subjecting it to the GSEA analysis in order to limit noise and aim for a more robust result.

Figure 2.38: Gene set enrichment analysis based on GO biological process.

Category	Description	Size	Test statistic	Lower tail	Upper tail
0006412	translation	204	-13,92	0,00	1,00

Figure 2.39: The result of a gene set enrichment analysis based on GO biological process.

2.9 Tutorial: Align Sequences

This tutorial outlines some of the alignment functionality of the *CLC Main Workbench*. In addition to creating alignments of nucleotide or peptide sequences, the software offers several ways to view alignments. The alignments can then be used for building phylogenetic trees.

Sequences must be available via the **Navigation Area** to be included in an alignment. If you have sequences open in a View that you have not saved, then you just need to select the view tab and press **Ctrl + S** (or **⌘ + S** on Mac) to save them.

In this tutorial six protein sequences from the Example data folder will be aligned. (See figure 2.110).

To align the sequences:

select the sequences from the 'Protein' folder under 'Sequences' | Toolbox | Alignments and Trees (📁) | Create Alignment (🔍)

Figure 2.40: Six protein sequences in 'Sequences' from the 'Protein orthologs' folder of the Example data.

2.9.1 The alignment dialog

This opens the dialog shown in figure 2.111.

Figure 2.41: The alignment dialog displaying the six protein sequences.

It is possible to add and remove sequences from **Selected Elements** list. Since we had already selected the eight proteins, just click **Next** to adjust parameters for the alignment.

Clicking **Next** opens the dialog shown in figure 2.112.

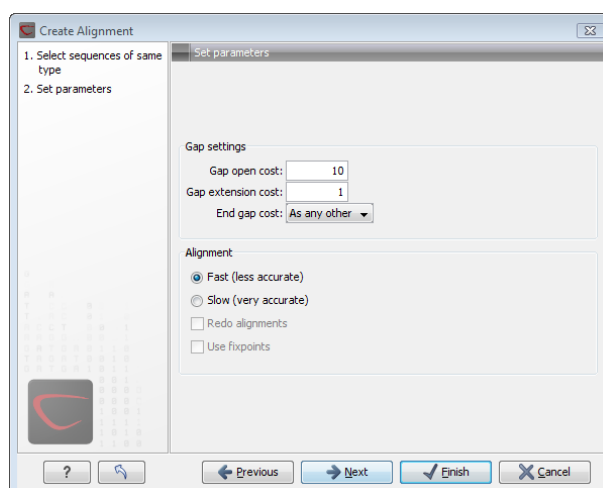

Figure 2.42: The alignment dialog displaying the available parameters which can be adjusted.

Leave the parameters at their default settings. An explanation of the parameters can be found

by clicking the help button (?). Alternatively, a tooltip is displayed by holding the mouse cursor on the parameters.

Click **Finish** to start the alignment process which is shown in the **Toolbox** under the **Processes** tab. When the program is finished calculating it displays the alignment (see fig. 2.113):

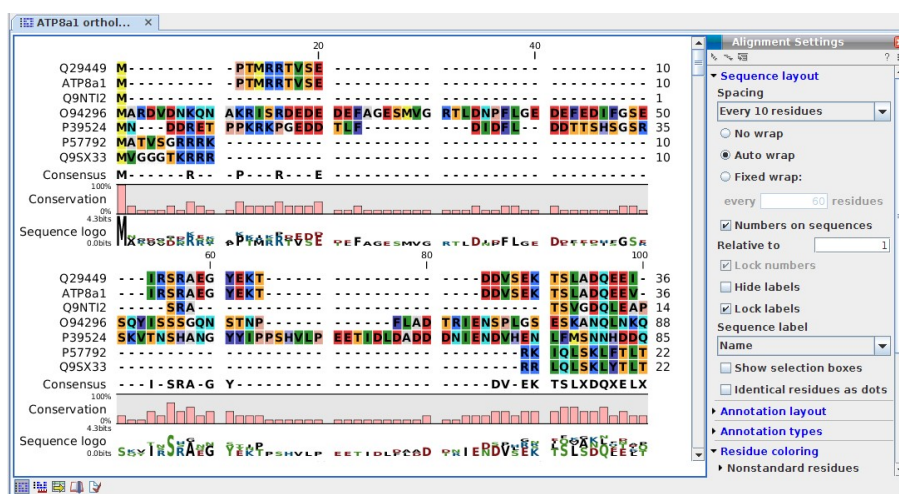

Figure 2.43: The resulting alignment.

Note! The new alignment is not saved automatically.

To save the alignment, drag the tab of the alignment view into the **Navigation Area**.

Installing the Additional Alignments plugin gives you access to two other alignment algorithms: ClustalW (Windows/Mac/Linux) and Muscle (Windows/Mac/Linux). The Additional Alignments Module can be downloaded from <http://www.clcbio.com/plugins>. Note that you will need administrative privileges on your system to install it.

2.10 Tutorial: Assembly

In this tutorial, you will see how to assemble data from automated sequencers into a contig and how to find and inspect any conflicts that may exist between different reads.

This tutorial shows how to assemble sequencing data generated by conventional "Sanger" sequencing techniques using the *CLC Main Workbench*. For high-throughput sequencing data, we refer to the *CLC Genomics Workbench* (see <http://www.clcbio.com/genomics>).

The data used in this tutorial are the sequence reads in the "Sequencing reads" folder in the "Sequencing data" folder of the **Example data** in the **Navigation Area**. If you do not have the example data, please go to the **Help** menu to import it.

2.10.1 Trimming the sequences

The first thing to do when analyzing sequencing data is to trim the sequences. Trimming serves a dual purpose: it both takes care of parts of the reads with poor quality, and it removes potential vector contamination. Trimming the sequencing data gives a better result in the further analysis.

Select the 9 sequences and click **Next**.

In this dialog, you will be able to specify how this trimming should be performed.

For this data, we wish to use a more stringent trimming, so we set the limit of the quality score trim to 0.02 (see figure 2.44).

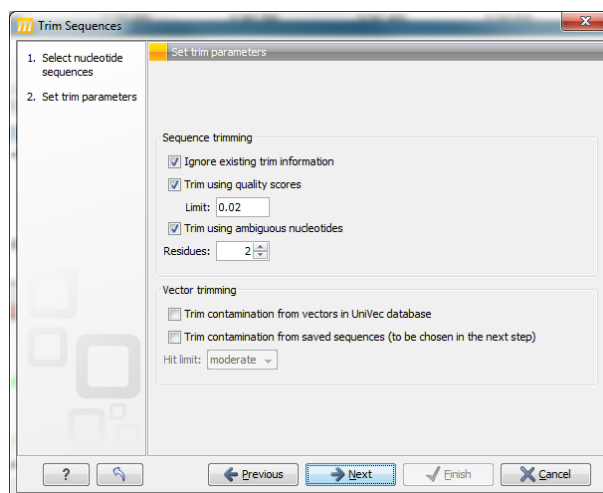

Figure 2.44: Specifying how sequences should be trimmed. A stringent trimming of 0.02 is used in this example.

There is no vector contamination in these data, so we only trim for poor quality.

If you place the mouse cursor on the parameters, you will see a brief explanation.

Click **Next** and choose to **Save** the results.

When the trimming is performed, the parts of the sequences that are trimmed are actually annotated, not removed (see figure 2.45). By choosing **Save**, the Trim annotations will be saved directly to the sequences, without opening them for you to view first.

Figure 2.45: Trimming creates annotations on the regions that will be ignored in the assembly process.

These annotated parts of the sequences will be ignored in the subsequent assembly.

A natural question is: Why not simply delete the trimmed regions instead of annotating them? In some cases, deleting the regions would do no harm, but in other cases, these regions could potentially contain valuable information, and this information would be lost if the regions were deleted instead of annotated. We will see an example of this later in this tutorial.

2.10.2 Assembling the sequencing data

The next step is to assemble the sequences. This is the technical term for aligning the sequences where they overlap and reverse the reverse reads to make a contiguous sequence (also called a

contig).

In this tutorial, we will use assembly to a reference sequence. This can be used when you have a reference sequence that you know is similar to your sequencing data.

Toolbox | Sequencing Data Analysis (AA) | Assemble Sequences to Reference (MW)

In the first dialog, select the nine sequencing reads and click **Next** to go to the second step of the assembly where you select the reference sequence.

Click the **Browse and select** button (📁) and select the "ATP8a1 mRNA (reference)" from the "Sequencing data" folder (see figure 2.46). You can leave the other options in this window set to their defaults.

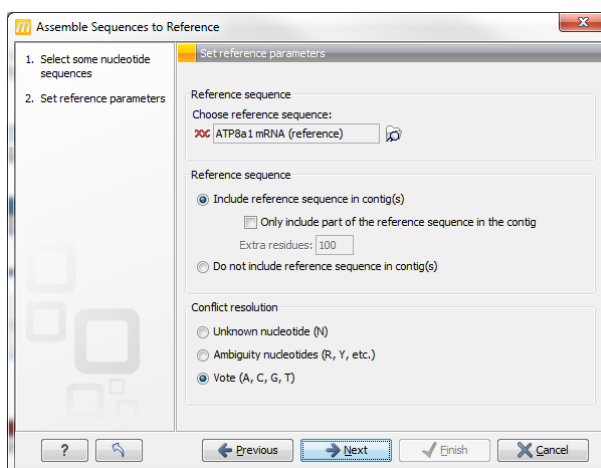

Figure 2.46: The "ATP8a1 mRNA (reference)" sequence selected as reference sequence for the assembly.

Click **Next** and choose to use the trim information (that you have just added).

Click **Finish** and the assembly process will begin.

2.10.3 Getting an overview of the contig

The result of the assembly is a **Contig** which is an alignment of the nine reads to the reference sequence. Click **Fit width** (📏) to see an overview of the contig. To help you determine the coverage, display a coverage graph (see figure 2.47):

Alignment info in Side Panel | Coverage | Graph

This overview can be an aid in determining whether coverage is satisfactory, and if not, which regions a new sequencing effort should focus on. Next, we go into the details of the contig.

2.10.4 Finding and editing conflicts

Click **Zoom to 100%** (🔍) to zoom in on the residues at the beginning of the contig. Click the **Find Conflict** button at the top of the **Side Panel** or press the **Space** key to find the first position where there is disagreement between the reads (see figure 2.48).

In this example, the first read has a "T" (marked with a light-pink background color), whereas the second line has a gap. In order to determine which of the reads we should trust, we assess the

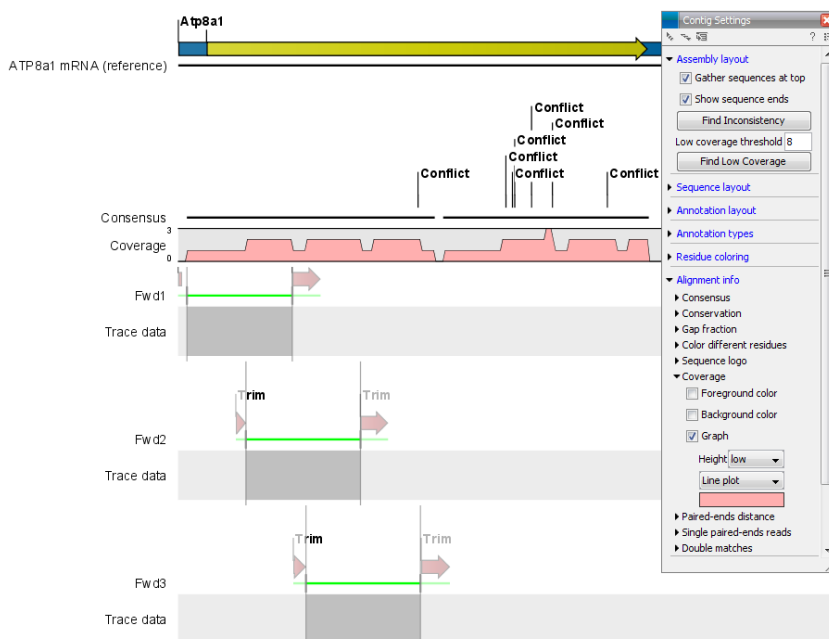

Figure 2.47: An overview of the contig with the coverage graph.

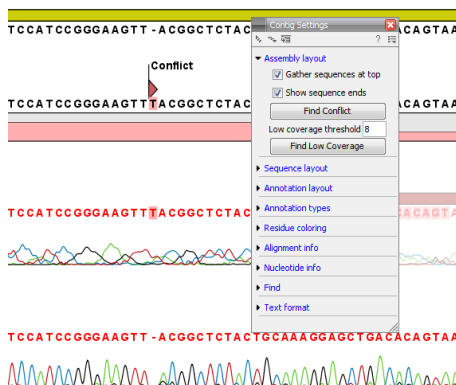

Figure 2.48: Using the Find Conflict button highlights conflicts.

quality of the read at this position.

A quick look at the regularity of the peaks of read "Rev2" compared to "Rev3" indicates that we should trust the "Rev2" read. In addition, you can see that we are close to the end of the end of "Rev3", and the quality of the chromatogram traces is often low near the ends.

Based on this, we decide not to trust "Rev3". To correct the read, select the "T" in the "Rev3" sequence by placing the cursor to the left of it and dragging the cursor across the T. Press **Delete** (🗑️).

This will resolve the conflict.

2.10.5 Including regions that have been trimmed off

Clicking the **Find Conflict** button again will find the next conflict.

This is the beginning of a stretch of gaps in the consensus sequence. This is because the reads have been trimmed at this position. However, if you look at the read at the bottom, *Fwd2*, you

can see that a lot of the peaks actually seem to be fine, so we could just as well include this information in the contig.

If you scroll a little to the right, you can see where the trimmed region begins. To include this region of Fwd2 in the contig, move the vertical slider at position 2073 to the left (see figure 19.21).

Figure 2.49: *Dragging the edge of the trimmed region.*

You will now see how the gaps in the consensus sequence are replaced by real sequence information.

Note that you can only move the sliders when you are zoomed in to see the sequence residues.

2.10.6 Inspecting the traces

Clicking the **Find Conflict** button again will find the next conflict.

Here both reads are different than the reference sequence. We now inspect the traces in more detail. In order to see the details, we zoom in on this position:

Zoom in using the Tool Bar zoom function (🔍) | Click the selected base | Click again three times

Now you have zoomed in on the trace (see figure 2.50).

Figure 2.50: *Now you can see all the details of the traces.*

This gives more space between the residues, but if we would like to inspect the peaks even more, simply drag the peaks up and down with your mouse (see figure 19.2).

Figure 2.51: *Grab the traces to scale.*

2.10.7 Synonymous substitutions?

In this case we have sequenced the coding part of a gene. Often you want to know what a variation like this would mean on the protein level. To do this, show the translation along the contig:

Nucleotide info in the Side Panel | Translation | Show | Select ORF/CDS in the Frame box

The result is shown in figure 2.52.

Figure 2.52: *Showing the translation along the contig.*

You can see that the variation is on the third base of the codon coding for threonine, so this is a synonymous substitution. That is why the T is colored yellow. If it was a non-synonymous substitution, it would be colored in red.

2.10.8 Getting an overview of the conflicts

Browsing the conflicts by clicking the **Find Conflict** button is useful in many cases, but you might also want to get an overview of all the conflicts in the entire contig. This is easily achieved by showing the contig in a table view:

Press and hold the Ctrl-button (⌘ on Mac) | Click Show Table (📄) at the bottom of the view

This will open a table showing the conflicts. You can right-click the **Note** field and enter your own comment. In this dialog, enter a new text in the **Name** and click **OK**.

When you edit a comment, this is reflected in the conflict annotation on the consensus sequence. This means that when you use this sequence later on, you will easily be able to see the comments you have entered. The comment could be e.g. your interpretation of the conflict.

2.10.9 Documenting your changes

Whenever you make a change like deleting a "T", it will be noted in the contig's history. To open the history, click the fHistory (📖) icon at the bottom of the view.

In the history, you can see the details of each change (see figure 2.53).

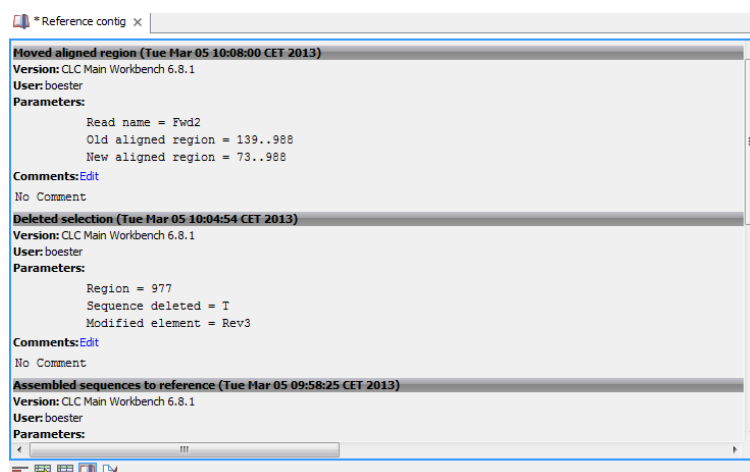

Figure 2.53: The history of the contig showing that a "T" has been deleted and that the aligned region has been moved.

2.10.10 Using the result for further analyses

When you have finished editing the contig, it can be saved, and you can also extract and save the consensus sequence:

Right-click the name "Consensus" | Open Sequence | Save (💾)

This will make it possible to use this sequence for further analyses in the *CLC Main Workbench*. All the conflict annotations are preserved, and in the sequence's history, you will find a reference to the original contig. As long as you also save the original contig, you will always be able to go back to it by choosing the Reference contig in the consensus sequence's history (see figure 2.54).

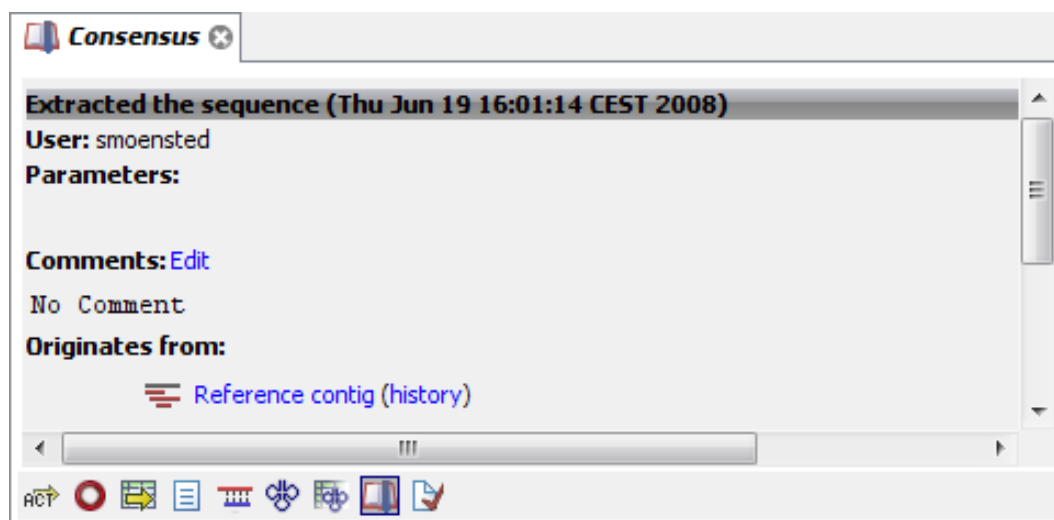

Figure 2.54: The history of the consensus sequence, which has been extracted from the contig. Clicking the blue text "Reference contig" will find and highlight the name of the saved contig in the Navigation Area. Clicking the blue text "history" to the right will open the history view of the earlier contig. From there, you can choose other views, such as the Read mapping view, of the contig.

2.11 Tutorial: In Silico Cloning Work Flow

In this tutorial, the goal is to make a virtual PCR-amplification of a gene using primers with restriction sites at the 5' ends, and to insert the gene in a multiple cloning site of an expression vector. We start off with a set of primers, a DNA template sequence and an expression vector loaded into the Workbench.

This tutorial will guide you through the following steps:

1. Adding restriction sites to the primers
2. Simulating the effect of PCR by creating the fragment to use for cloning.
3. Specifying restriction sites to use for cloning, and inserting the fragment into the vector

2.11.1 Locating the data to use

Open the `Example data` folder in the **Navigation Area**. Open the `Cloning` folder, and inside this folder, open the `Primers` folder.

If you do not have the example data, please go to the **Help** menu to import it.

The data to use in these folders is shown in figure 2.55.

Double-click the `ATP8a1 mRNA` sequence and zoom to **Fit Width** () and you will see the yellow annotation which is the coding part of the gene. This is the part that we want to insert into the `pcDNA4_TO` vector. The primers have already been designed using the primer design tool in *CLC Main Workbench* (to learn more about this, please refer to the Primer design tutorial).

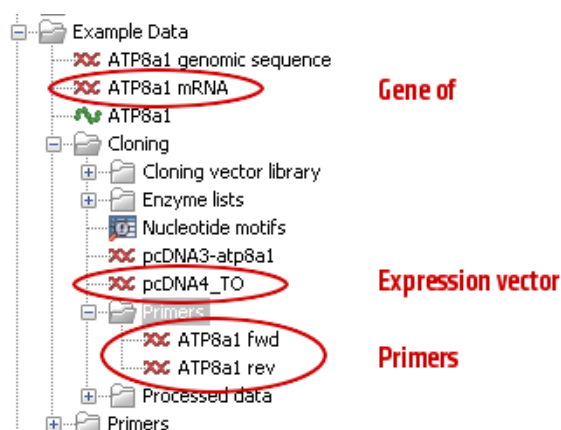

Figure 2.55: The data to use in this tutorial.

2.11.2 Add restriction sites to primers

First, we add restriction sites to the primers. In order to see which restriction enzymes can be used, we create a split view of the vector and the fragment to insert. In this way we can easily make a visual check to find enzymes from the multiple cloning site in the vector that do not cut in the gene of interest. To create the split view:

double-click the pcDNA4_TO sequence | View | Split Horizontally (☰)

Note that this can also be achieved by simply dragging the pcDNA4_TO sequence into the lower part of the open view.

Switch to the **Circular** (⊙) view at the bottom of the view.

Zoom in (🔍) on the multiple cloning site downstream of the green CMV promoter annotation. You should now have a view similar to the one shown in figure 2.56.

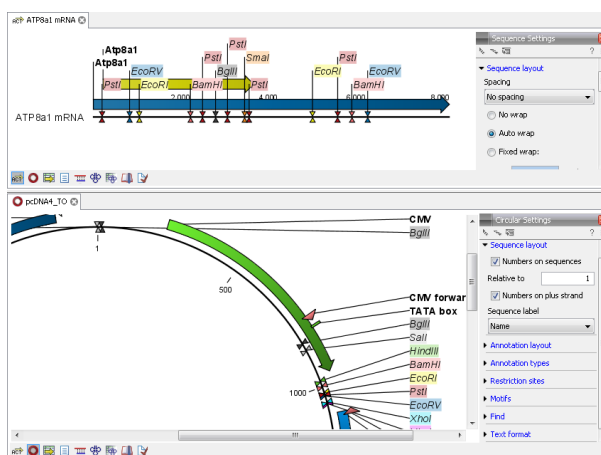

Figure 2.56: Check cut sites.

By looking at the enzymes we can see that both *HindIII* and *XhoI* cut in the multi-cloning site of the vector and not in the *Atp8a1* gene. Note that you can add more enzymes to the list in the **Side Panel** by clicking **Manage Enzymes** under the **Restriction Sites** group.

Close both views and open the *ATP8a1 fwd* primer sequence. When it opens, double-click the name of the sequence to make a selection of the full sequence. If you do not see the whole

sequence turn purple, please make sure you have the Selection Tool chosen, and not one of the other tools available from the top right side of the Workbench (e.g. Pan, Zooming tools, etc.)

Once the sequence is selected, right-click and choose to **Insert Restriction Site Before Selection** as shown in figure 2.57.

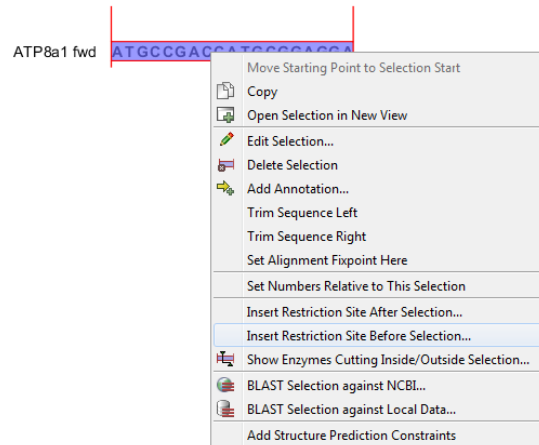

Figure 2.57: Adding restriction sites to a primer.

In the **Filter** box enter *HindIII* and click on it. At the bottom of the dialog, add a few extra bases 5' of the cut site (this is done to increase the efficiency of the enzyme) as shown figure 21.14.

Figure 2.58: Adding restriction sites to a primer.

Click **OK** and the sequence will be inserted at the 5' end of the primer as shown in figure 2.59.

Figure 2.59: Adding restriction sites to a primer.

Perform the same process for the ATP8a1 rev primer, this time using *XhoI* instead. This time, you should also add a few bases at the 5' end as was done in figure 21.14 when inserting the *HindIII* site.

Note! The `ATP8a1_rev` primer is designed to match the negative strand, so the restriction site should be added at the 5' end of this sequence as well (**Insert Restriction Site before Selection**).

Save (📁) the two primers and close the views and you are ready for next step.

2.11.3 Simulate PCR to create the fragment

Now, we want to extract the PCR product from the template `ATP8a1 mRNA` sequence using the two primers with restriction sites.

In the *CLC Main Workbench*:

Toolbox | Primers and Probes (📁) | **Find Binding Sites and Create Fragments** (🔍)

In the *CLC Genomics Workbench*:

Toolbox | Molecular Biology Tools (🔍) | **Primers and Probes** (📁) | **Find Binding Sites and Create Fragments** (🔍)

Select the `ATP8a1 mRNA` sequence and click **Next**. In this dialog, use the **Browse** (📁) button to select the two primer sequences. Click **Next** and adjust the output options as shown in figure 2.60.

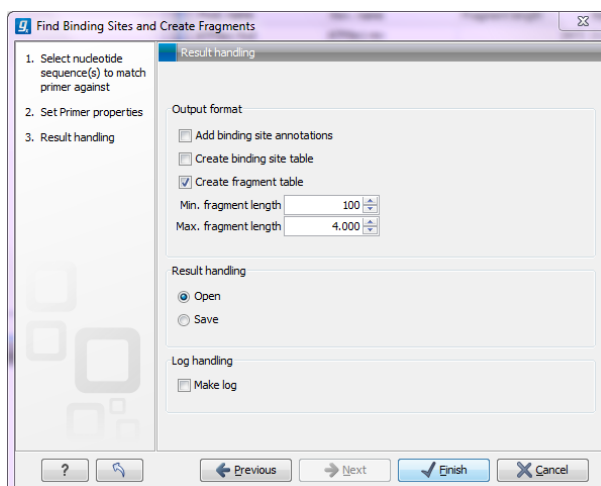

Figure 2.60: Creating the fragment table including fragments up to 4000 bp.

Click **Finish** and you will now see the fragment table displaying the PCR product.

In the **Side Panel** you can choose to show information about melting temperature for the primers.

Right-click the fragment and select **Open Fragment** as shown in figure 2.61.

Figure 2.61: Opening the fragment as a sequence.

This will create a new sequence representing the PCR product. **Save** (📁) the sequence in the *Cloning* folder and close the views. You do not need to save the fragment table.

2.11.4 Specify restriction sites and perform cloning

The final step in this tutorial is to insert the fragment into the cloning vector:

Toolbox in the Menu Bar | Cloning and Restriction Sites (🔗) | Cloning (🔗)

Select the **Fragment** (ATP8a1 mRNA (ATP8a1 fwd - ATP8a1 rev)) sequence you just saved and click **Next**. In this dialog, use the **Browse** (🔗) button to select pcDNA4_TO cloning vector also located in the **Cloning** folder. Click **Finish**.

You will now see the cloning editor where you will see the pcDNA4_TO vector in a circular view. Press and hold the **Ctrl** (⌘ on Mac) key while you click first the *HindIII* site and next the *XhoI* site (see figure 2.62).

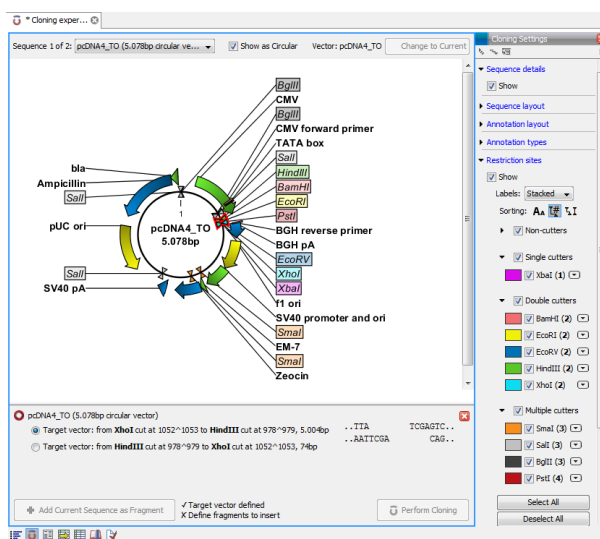

Figure 2.62: Press and hold the **Ctrl** key while you click first the *HindIII* site and next the *XhoI* site in the cloning vector.

At the bottom of the view you can now see information about how the vector will be cut open. Since the vector has now been split into two fragments, you can decide which one to use as the target vector. If you selected first the *HindIII* site and next the *XhoI* site, the *CLC Main Workbench* has already selected the right fragment as the target vector. If you click one of the vector fragments, the corresponding part of the sequence will be high-lighted.

Next step is to cut the fragment. At the top of the view you can switch between the sequences used for cloning (at this point it says pcDNA4_TO 5.078bp circular vector). Switch to the fragment sequence and perform the same selection of cut sites as before while pressing the **Ctrl** (⌘ on Mac) key. You should now see a view identical to the one shown in figure 2.63.

When this is done, the **Perform Cloning** (🔗) button at the lower right corner of the view is active because there is now a valid selection of both fragment and target vector. Click the **Perform Cloning** (🔗) button and you will see the dialog shown in figure 2.64.

This dialog lets you inspect the overhangs of the cut site, showing the vector sequence on each side and the fragment in the middle. The fragment can be reverse complemented by clicking the **Reverse complement fragment** (🔗) but this is not necessary in this case. Click **Finish** and your new construct will be opened.

When saving your work, there are two options:

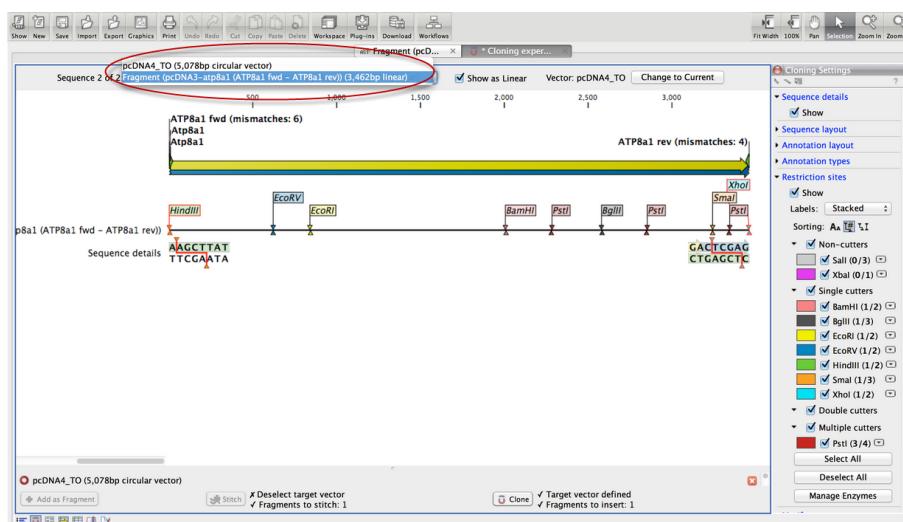

Figure 2.63: Change the view to display the fragment sequence. Press and hold the Ctrl key while you click first the HindIII site and next the XhoI site.

Figure 2.64: Showing the insertion point of the vector

- Save the Cloning Experiment. This is saved as a sequence list, including the specified cut sites. This is useful if you need to perform the same process again or double-check details.
- Save the construct shown in the circular view. This will only save the information on the particular sequence including details about how it was created (this can be shown in the **History** view).

You can, of course, save both. In that case, the history of the construct will point to the sequence list in its own history.

The construct is shown in figure 2.65.

2.12 Tutorial: Gateway Cloning

This tutorial will show you how to use the Workbench tool for in silico Gateway®Cloning. With this you can perform both standard (1 fragment) and multi-site Gateway Cloning. Here we focus on the 1-fragment cloning approach, but we provide tips to help you move onto multi-site Gateway Cloning easily.

For information on the Gateway Cloning system please visit:

<http://www.invitrogen.com/site/us/en/home/Products-and-Services/Applications/Cloning/Gateway-Cloning.html>.

After you have the Gateway Cloning vectors imported into your Workbench (section 2.12.1), you work through the three Gateway Cloning tools, which imitate the steps of the Gateway Cloning

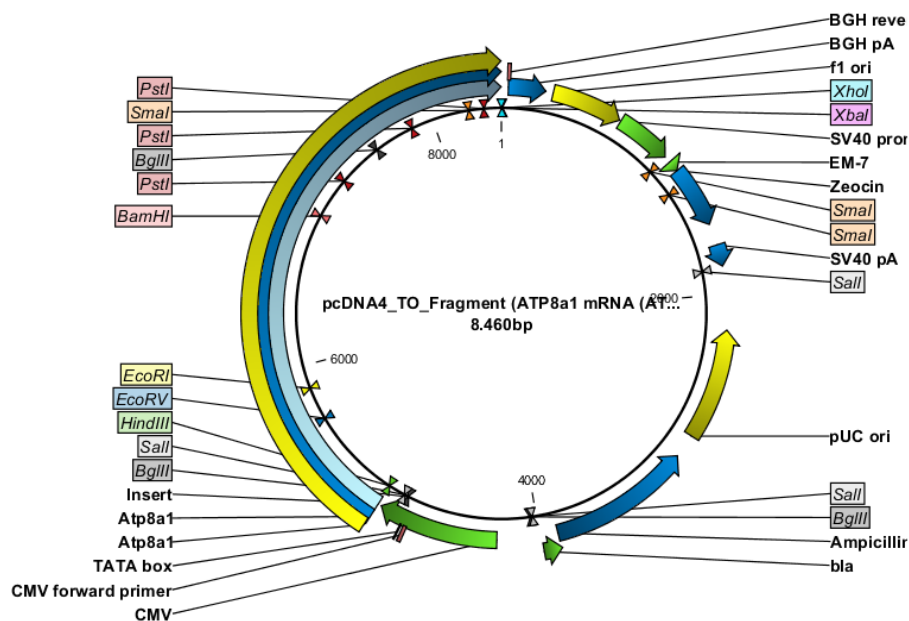

Figure 2.65: The *Atp8a1* gene inserted after the CMV promoter

lab procedure. You will:

- Add attB sites to the fragment of interest, as would be done in the lab using PCR. (Section 2.12.2)
- Construct an entry vector by an attB/attP recombination event (BP reaction) in which the attB-flanked fragment is exchanged for the attP-flanked sequence of the chosen donor vector. (Section 2.12.3)
- Construct the final expression vector by an attL/attR recombination event (LR reaction) in which the target fragment of the entry vector is exchanged for the attR-flanked sequence of a chosen destination vector. (Section 2.12.4)

2.12.1 Importing Gateway Cloning vectors

1. To perform the in silico Gateway Cloning we first need to import donor and destination vectors. A file of these can be downloaded from the Invitrogen web site:

<http://tools.invitrogen.com/downloads/Gatewayvectors.ma4>

2. Once downloaded, create a folder in your Workbench to import this file into.
3. Select this new folder by clicking on it.
4. Now, import the vector sequences into the Workbench using the **standard import tool**.

The vector sequences should now be imported into your new folder.

For future reference, information on the vectors for MultiSite Gateway Cloning can be found on the Invitrogens web site: <http://www.invitrogen.com/search/global/searchAction.action?query=MultiSite+Gateway%C2%AE+Vectors&resultPage=1&resultsPerPage=>

15&navigator=seproductcategorynavigator&modifier=DNA+Vectors%2FMultiSite+Gateway%26reg%3B+Vectors&seSeeallNavigator=true.

If you choose which type of MultiSite Cloning you wish to perform (number of fragments), then the relevant vectors can be listed. Vector information can then be downloaded from the linked areas on the site.

2.12.2 Adding attB sites

This step mimics the lab PCR procedure of adding attB sites to the target fragment making it eligible for recombination into the donor vector. The output can also include a set of primers, although we do not do that in this tutorial.

Our target fragment is the coding sequence (CDS) of ATP8a1, the mRNA of which is found in the standard example data you can download into the Workbench. If you do not already have the example data go to the **Help** menu in the Workbench, and choose to **Import Example Data**.

Now:

1. Extract the CDS sequence from the ATP8a1 mRNA file. To do this,
 - Double click on the sequence object called **ATP8a1 mRNA**. This opens it in the viewing area of the Workbench.
 - Right-click the CDS annotation, which by default will be coloured in yellow, and chose **Open annotation in New View**
 - Save the new data object that has just opened in the new view. There are different ways to do this. Two options are:
 - (a) Right click on the tab at the top of the new view, and choose Save As... from the menu that appears, or
 - (b) Move the cursor over the tab at the top of the new view, press the left mouse button. Keeping the mouse button down, drag the tab over into a folder in the Navigation area of the Workbench. The data will then be saved into that folder.
2. Add the attB sites. To do this,
 - Start the **Gateway Cloning** tool:
Toolbox | Cloning and Restriction Sites (📁) | Gateway Cloning | Add attB Sites (🔧)
 - In the wizard, select the ATP8a1 CDS fragment you just saved. When the wizard starts up, that fragment should be in the list of **Selected Elements**. If it is not, please select it in the wizard, and click on the right hand arrow to add it to the **Selected Elements** list.
 - Click on the button marked **Next**.
 - It is in this step of the wizard you choose the attB sites to be added to your fragment. This is shown in figure 2.66. The sites to choose depend on your choice of donor vector. We will be going with the default option of attB1 and attB2. This ensures compatibility with our downstream choice of donor vector, which will be **pDONR221**.
 - Click on the button marked **Next**.

Figure 2.66: Adding attB sites.

If you have selected more than one fragment these will all be given the same combination of attB sites. If you wish to add different combination of sites you will have to run the tool once for each combination.

3. Next you will be given the option to insert additional elements downstream and upstream of the first and second attB site, respectively. That is, to insert elements immediately 5 prime and 3 prime of the fragment.

We will add a Shine-Dalgarno site 5 prime of ATP8a1. Click in the field **Forward primer additions** and press on the keys Shift+F1 to bring up a list of elements you can choose from. Use either the mouse or the up and down arrow keys and enter to select the Shine-Dalgarno site. See figure 2.67.

4. Insert 8 random nucleotides after the Shine-Dalgarno sequence. This is done by simply typing in the bases. See figure 2.68. Doing this ensures that the spacing between the Shine-Dalgarno sequence and the initiation codon is correct.

You will find a preview of the final PCR product below. Any preset additional elements appear in green whereas the bases typed in manually are displayed in blue.

5. Click on the button marked **Next**.
6. In this step, you can choose the length of the template-specific part of your primers. See figure 2.69.

This template-specific fragment is joined with the attB site and any additional elements you choose to make up the primer. Here, we will just keep the defaults.

7. Click on the button marked **Next**.
8. Choose to **Save** the results. Uncheck the **create primer list** option as we will not be needing this in this tutorial. See figure 2.70.
9. Click on the button marked **Next** and choose where to **Save** the output.

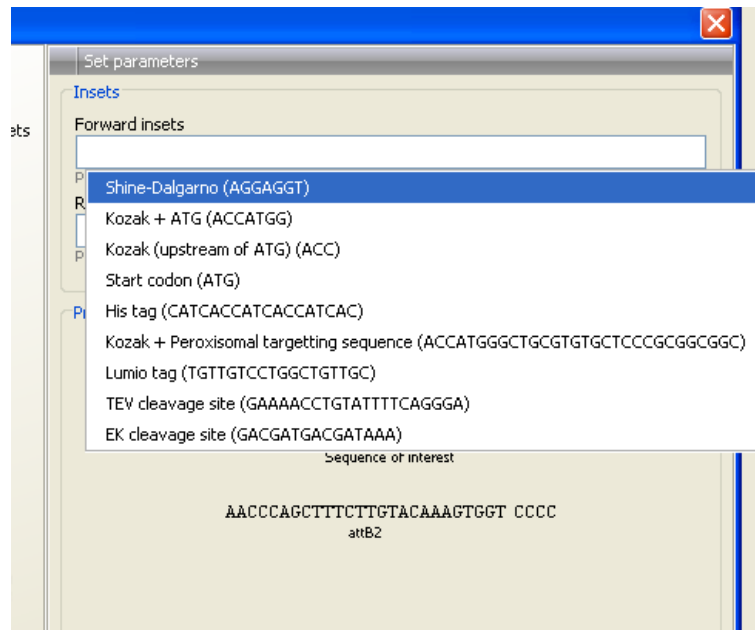

Figure 2.67: Choose Shine-Dalgarno.

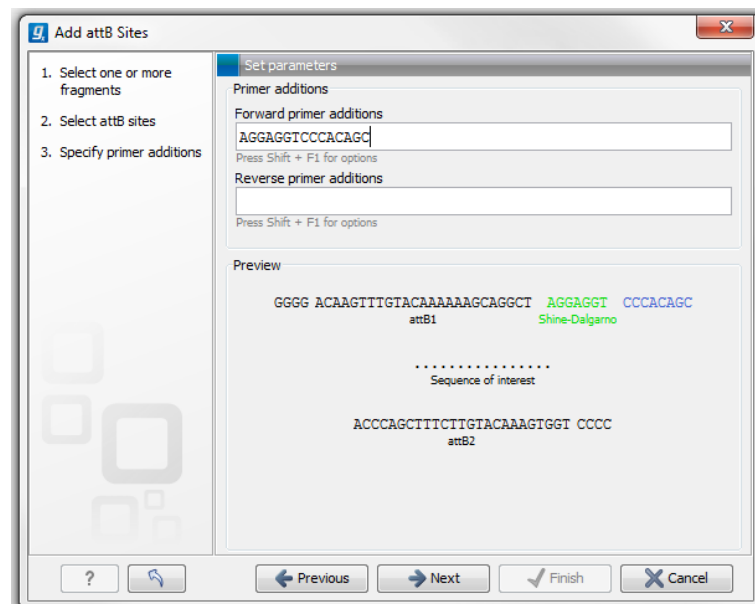

Figure 2.68: Add bases to ensure correct spacing between the Shine-Dalgarno sequence and the initiation codon.

10. Open up the result **ATP8a1 CDS (attB1 attB2)** to have a look. See figure 2.71.
11. In the side panel called **Sequenc Settings**, find the section called **Annotation types**. Click on it to expand it.
12. Click on the box beside **RBS** to mark it, so that the Shine-Dalgarno ribosomal binding site annotation is displayed. Note also that you can see annotations for primer regions and the attB sites.

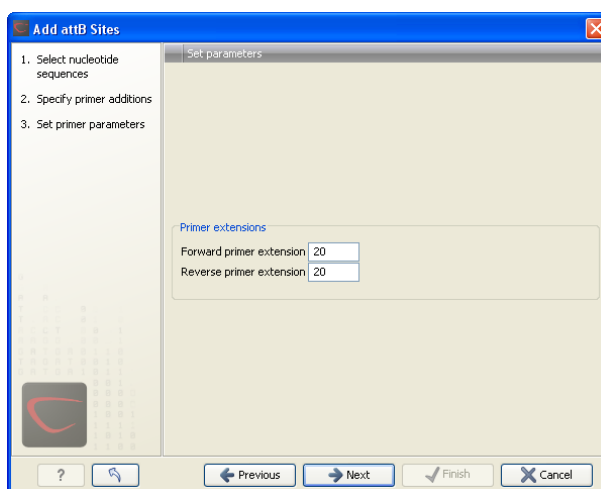

Figure 2.69: Set the appropriate primer lengths.

Figure 2.70: Choose to save your results.

2.12.3 Creation of an entry vector

This step recombines the attB-flanked ATP8a1 into the donor vector, which is **pDONR221**, resembling the BP-reaction carried out in the lab.

1. Choose **Create Entry Clone** from under the Gateway Cloning menu:
Toolbox | Cloning and Restriction Sites (📁) | Gateway Cloning | Create Entry Clone (🔄)
2. In the dialog select the result that you generated earlier: **ATP8a1 CDS (attB1 attB2)**. Then click on the button marked **Next**.
3. Click the **Browse button** (📁) and find the Gateway folder of vectors, which was previously imported.
4. Select donor vector **pDONR221** as shown in figure 2.72 and click on the button labelled **OK**.
5. Click on the button labelled **Next**.

Note: The Workbench only checks the chosen entry clone for valid attP sites. It does **not** check that these are compatible with the attB sites present in the fragment. You need to

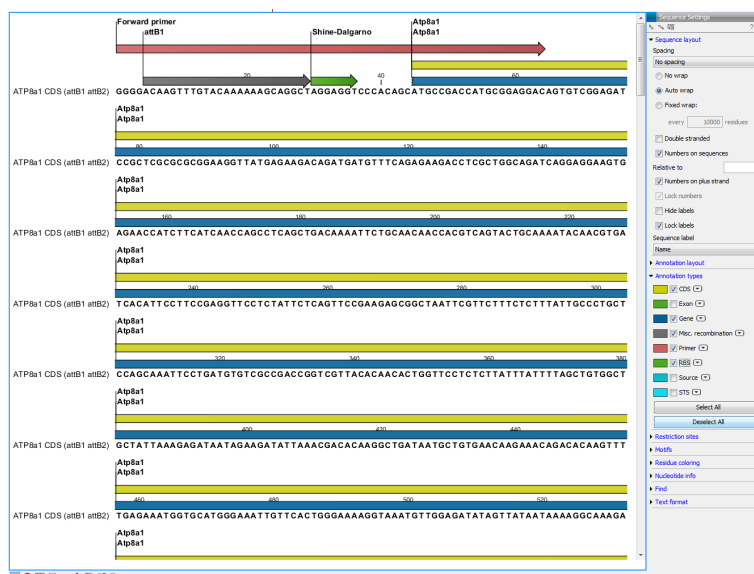

Figure 2.71: A view of the results: ATP8a1 CDS (attB1 attB2).

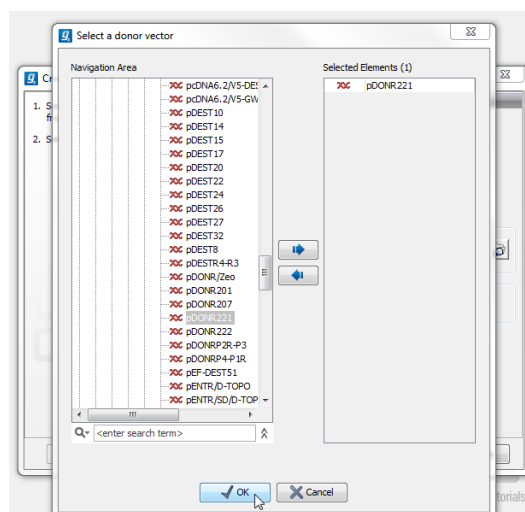

Figure 2.72: Select the donor vector, which in this case is pDONR221.

make sure that a valid entry vector is used for the attB-fragment of interest. If the right combination of attB and attP sites is not found, no entry clones will be produced.

6. Choose to **Save** the result and click on the button labelled **Next** to be able to specify where to save the results to.
7. Click on the button labelled **Finish**.
8. Open the output **pDONR221 (ATP8a1 CDS (attB1 attB2))** to have a look at it. To see a view like that shown in figure 2.73:
 - Go to circular view (🕒).
 - Check annotation type **RBS** in the side panel to get a better view. The attB/attP recombination event has resulted in the fragment of interest being inserted into the vector. The fragment is flanked by attL sites.

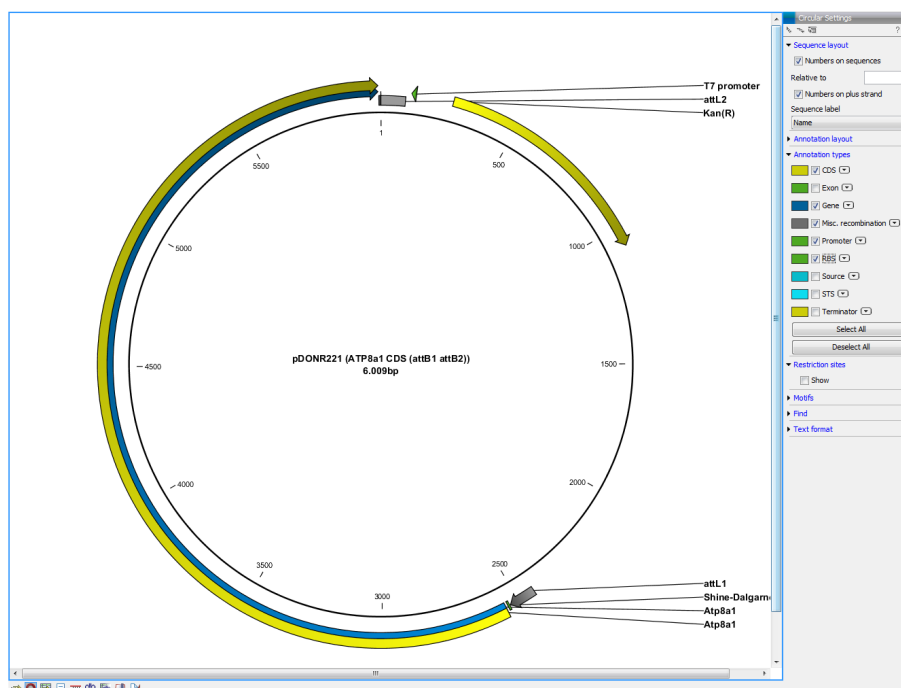

Figure 2.73: View the donor vector, pDONR221, after the entry clone is createdXXX.

If several fragments were selected for input (using the batch option), the output would be one entry clone per fragment, all based on the same donor vector.

2.12.4 Creating an expression vector (LR)

This last step in a Gateway Cloning workflow mimics the lab LR recombination reaction. That is, the fragment of interest is recombined from the entry vector into a destination vector (the LR reaction) to create the final expression vector.

In this tutorial we are carrying out a standard, single fragment Gateway Cloning task. Thus we will choose only one entry clone as input during this step. For MultiSite Gateway Cloning, we would choose all the entry clones to be joined in the final expression vector. Note though that if you do this, you need to ensure that the entry clones contain a valid combination of attL sites. For more information on this please have a look at the MultiSite Gateway explanation on the Invitrogen webpage:

<http://tools.invitrogen.com/downloads/gateway-multisite-seminar.html>

The steps to create an expression clone are:

1. Choose **Create Expression Clone** from under the Gateway Cloning menu:

Toolbox | Cloning and Restriction Sites (🔗) | Gateway Cloning | Create Expression Clone (🔗)

2. In the dialog box select the entry clone you created in the previous step and click on the button marked **Next**.
3. In the next window, click the **Browse** button and navigate to the Gateway vector folder. Select the destination vector: **pDEST14** and click on the button labelled **OK**.

4. Click on the button labelled **Next**.

The Workbench only checks for valid attR sites in the destination vectors. You, yourself, need to make sure that the attL and attR sites are compatible. If not, no expression clone will be created.

5. In the next window choose to open the result. If you would like to also have a look at the byproduct, check the corresponding box. Click on the button labelled **Finish**.

The output is the result of the recombination between the attL and attR sites. The fragment of interest is now inserted in the expression vector flanked by attB sites, see figure 2.74

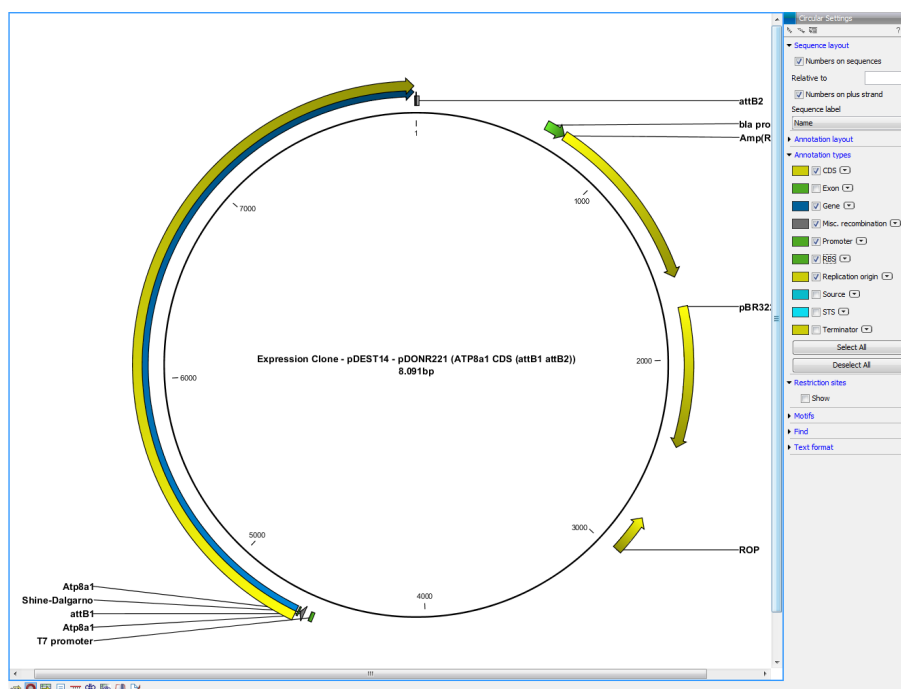

Figure 2.74: View the finished expression vector.

This concludes the Gateway Cloning tutorial. Below is a section outlining the general steps you could take in the case of MultiSite Gateway Cloning.

2.12.5 Short suggestion for a MultiSite Gateway Workflow using 2 fragments

The vectors mentioned in this section can be downloaded from Invitrogens web page:

<http://tools.invitrogen.com/downloads/Gatewayvectors.ma4>

1. Choose two fragments, which you would like to have in the final vector.
2. Create the following fragments:
 - Add attB1 and attB5r sites to sequence of interest 1 → sequence of interest 1 (attB1 attB5r)
 - Add attB5 and attB2 sites to sequence of interest 2 → sequence of interest 2 (attB5 attB2)

3. Create two entry vectors:

- sequence of interest 1 (attB1attB5r) + pDONR221-P1P5r
- sequence of interest 2 (attB5 attB2) + pDONR221-P5P2

4. Create the final expression vector by selecting:

- the first entry clone: pDONR221-P1P5r (fragment of interest 1(attB1 attB5r)), and
- the second entry clone: pDONR221-P1P5r (fragment of interest 1(attB1 attB5r))
- the destination vector: pDEST14

2.13 Tutorial: Primer Design

In this tutorial, you will see how to use the *CLC Main Workbench* to find primers for PCR amplification of a specific region.

We use the pcDNA3-atp8a1 sequence from the 'Primers' folder in the Example data. This sequence is the pcDNA3 vector with the atp8a1 gene inserted. In this tutorial, we wish design primers that would allow us to generate a PCR product covering the insertion point of the gene. This would let us use PCR to check that the gene is inserted where we think it is.

First, open the sequence in the Primer Designer:

Select the pcDNA3-atp8a1 sequence | Show (📄) | Primer Designer (🔍)

Now the sequence is opened and we are ready to begin designing primers.

2.13.1 Specifying a region for the forward primer

First zoom out to get an overview of the sequence by clicking **Fit Width** (📏). You can now see the blue gene annotation labeled Atp8a1, and just before that there is the green CMV promoter. This may be hidden behind restriction site annotations. Remember that you can always choose not to Show these by altering the settings in the right hand pane.

In this tutorial, we want the forward primer to be in a region between positions 600 and 900 - just before the gene (you may have to zoom in (🔍) to make the selection). Select this region, right-click and choose "Forward primer region here" (➡) (see figure 2.75).

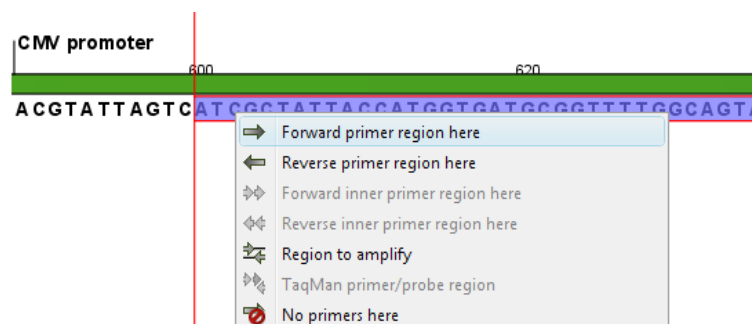

Figure 2.75: Right-clicking a selection and choosing "Forward primer region here".

This will add an annotation to this region, and five rows of red and green dots are seen below as shown in figure 2.76:

Figure 2.76: Five lines of dots representing primer suggestions. There is a line for each primer length - 18bp through to 22 bp.

2.13.2 Examining the primer suggestions

Each line consists of a number of dots, each representing the *starting point* of a possible primer. E.g. the first dot on the first line (primers of length 18) represents a primer starting at the dot's position and with a length of 18 nucleotides (shown as the white area in figure 2.77):

Figure 2.77: The first dot on line one represents the starting point of a primer that will anneal to the highlighted region.

Position the mouse cursor over a dot. A box will appear, providing data about this primer. Clicking the dot will select the region where that primer would anneal. (See figure 2.78):

Figure 2.78: Clicking the dot will select the corresponding primer region. Hovering the cursor over the dot will bring up an information box containing details about that primer.

Note that some of the dots are colored red. This indicates that the primer represented by this dot does not meet the requirements set in the **Primer parameters** (see figure 2.79):

The default maximum melting temperature is 58. This is the reason why the primer in figure 2.78 with a melting temperature of 58.55 does not meet the requirements and is colored red.

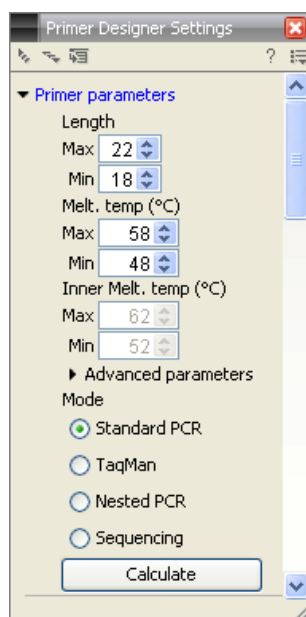

Figure 2.79: The Primer parameters.

If you raise the maximum melting temperature to 59, the primer will meet the requirements and the dot becomes green.

In figure 2.78 there is an asterisk (*) before the melting temperature. This indicates that this primer does not meet the requirements regarding melting temperature. In this way, you can easily see why a specific primer (represented by a dot) fails to meet the requirements.

By adjusting the **Primer parameters** you can define primers to meet your specific needs. Since the dots are dynamically updated, you can immediately see how a change in the primer parameters affects the number of red and green dots.

2.13.3 Calculating a primer pair

Until now, we have been looking at the forward primer. To mark a region for the reverse primer, make a selection from position 1200 to 1400 and:

Right-click the selection | Reverse primer region here (←)

The two regions should now be located as shown in figure 2.80:

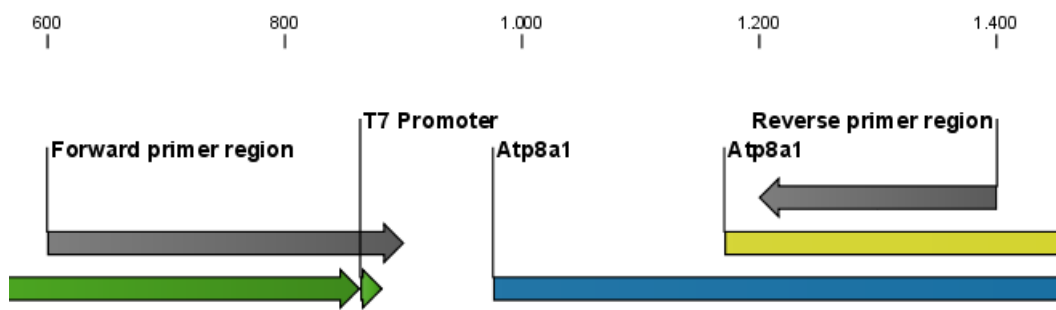

Figure 2.80: A forward and a reverse primer region.

Now, you can let *CLC Main Workbench* calculate all the possible primer pairs based on the **Primer**

parameters that you have defined:

Click the Calculate button (right hand pane) | Modify parameters regarding the combination of the primers (for now, just leave them unchanged) | Calculate

This will open a table showing the possible combinations of primers. To the right, you can specify the information you want to display, e.g. showing **Fragment length** (see figure 2.81):

Score	Pair annealing align (Fwd,Rev)	Fragment length...	Sequence Fwd	Melt. temp. Fwd	Sequence Rev	Melt. temp. Rev
62,56	GGTGGGAGGTCTATATAA AAGGAGATAAGAGTCAAGG	598,00	GGTGGGAGGTCTATATAA	48,572	GGAAGTGAAGATAGAGGAA	49,094
57,873	GGTGGGAGGTCTATATAA AAGGAGATAAGAGTCAAGG	598,00	GGTGGGAGGTCTATATAA	48,572	GGAAGTGAAGATAGAGGAA	49,566
55,921	GCGTGGATAGCGGTTTGA AGAACTAGTTGGTCCGAG	660,00	GCGTGGATAGCGGTTTGA	56,978	GAGGCTGGTTGATGAAGA	56,439

Figure 2.81: A list of primers. To the right are the Side Panel showing the available choices of information to display.

Clicking a primer pair in the table will make a corresponding selection on the sequence in the view above. At this point, you can either settle on a specific primer pair or save the table for later. If you want to use e.g. the first primer pair for your experiment, right-click this primer pair in the table and save the primers.

You can also mark the position of the primers on the sequence by selecting **Mark primer annotation on sequence** in the right-click menu (see figure 2.82):

This tutorial has shown some of the many options of the primer design functionalities of *CLC Main Workbench*. You can read much more using the program's **Help** function (?) or in the *CLC Main Workbench* user manual, linked to on this webpage: <http://www.clcbio.com/download>.

2.14 Tutorial: Working with Annotations

Annotations are the basis of many of the analyses in the Workbench. Once an annotation has been added to a sequence, it stays there even when the sequence is transformed to be part of an alignment, a BLAST result or a sequence list.

Because annotations are so fundamental to many of the tasks performed in the Workbench, there are a number of ways to browse, search for, view and edit annotations. This tutorial takes you through a lot of different areas of the Workbench to show some of the places where you can work with annotations.

2.14.1 Browsing and viewing annotations in sequence views

Open sequence *ATP8a1 mRNA* from the Example data by double-clicking the sequence. Click **Annotation types** in the **Side Panel** and you will see a list of the types of annotations on this sequence (shown in figure 2.83).

The image shows two screenshots of the Primer Designer software. The top screenshot displays a sequence view for 'pcDNA3-atp8a1' with annotations for 'T7 Promoter' and 'Atp8a1'. A right-click menu is open over a primer pair, with 'Mark Primer Annotation on Sequence' selected. The bottom screenshot shows a table of primers with columns for Score, Pair annealing align (Fwd, Rev), Fragment length, Sequence Fwd, Melt. temp. Fwd, Sequence Rev, and Melt. temp. Rev. A context menu is also visible over the table rows.

Score	Pair annealing align (Fwd, Rev)	Fragment length...	Sequence Fwd	Melt. temp. Fwd	Sequence Rev	Melt. temp. Rev
62,56	GCTGGGAGGCTCTATATAA AAGGAGATAAGAGTCAAGG			48,572	GGAAGTGAAGATAGAGGAA	49,094
57,873	GGTGGGAGGCTCTATATAA AAGGAGATAAGAGTCAAGG			48,572	GGAAGTGAAGATAGAGGA	49,566

Figure 2.82: The options available in the right-click menu. Here, "Mark primer annotation on sequence" has been chosen, resulting in two annotations on the sequence above (labeled "Oligo").

Click the *Exon* annotation type. This will show exon annotations on the sequence. As this sequence is very long, you cannot see the whole sequence, and the exons may therefore not be visible. In this situation, you can either Zoom out to find the annotations, or you can use the browse button (🔍) next to the annotation type to jump directly to one of the annotations (see figure 2.84).

Click *Exon 2*, and the beginning of the annotation will be visible in the view (see figure 2.85).

Annotations are displayed as arrows, going from left to right on the positive strand, and going from right to left on the negative strand. Placing your mouse cursor on the arrow will show additional information about the annotation. Try to place the mouse cursor on the blue gene annotation, and you can see more information about it (see figure 2.86).

This way of displaying and accessing annotations is similar for both circular views, alignments, and all other views displaying sequence residues.

2.14.2 Adding and editing annotations

You can add your own annotations to a sequence. A new annotation is most easily added if you first select a region on the sequence. In the upper view, select a region from residue 10 to 26 (see the status bar in the lower right corner of the Workbench). Then:

right-click the selection | Add Annotation (➡)

This will display a dialog where you can enter more information about the annotation. Enter *Test* as the name of the annotation (see figure 2.87).

Click **OK** and the annotation is added to the sequence (see figure 2.88).

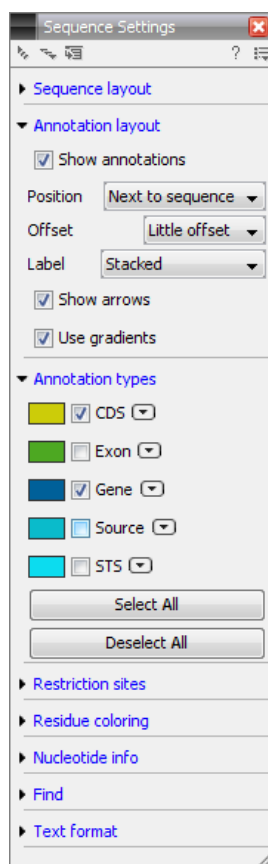

Figure 2.83: Annotation types of the *ATP8a1* mRNA sequence.

Figure 2.84: Click in the list to go directly to this annotation.

Now click the **Show Annotation Table**  icon at the bottom of the view. This will display a list of all the annotations on the sequence.

Enter *Test* into the **Filter** in the annotation table, and your newly added annotation will appear.

You can now double-click any of the **Name**, **Type** or **Region** fields to edit the annotation. Double-click the **Type** which is now "Misc. feature" and enter *My type* and press **Enter**.

The table should now look as shown in figure 2.89.

In this way, you can quickly edit annotations. If you double-click the **Qualifiers** cell, a dialog similar to the one in figure 2.87 will be shown.

Figure 2.85: The view jumps to the beginning of exon 2.

Figure 2.86: Information about the annotation.

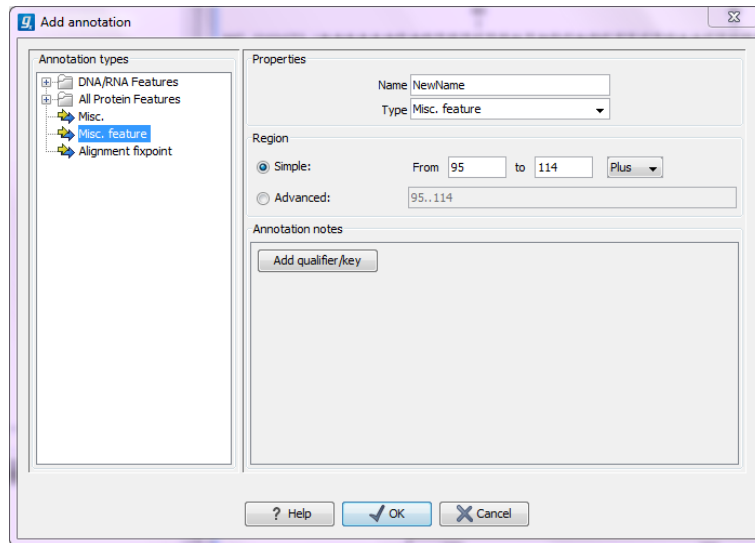

Figure 2.87: The Add Annotation dialog.

Figure 2.88: The annotation has been added.

2.14.3 Copying annotations

One of the more advanced features of the Workbench is the ability to copy and paste annotations. Annotations can be copied from one sequence to another or you can create a duplicate of the annotation by pasting it back on the same sequence. Because it is very easy to edit the region of the annotation, this can be a quick way of adding a number of similar annotations.

Select the *Test* annotation in the table | Copy (📄) | Paste (📄)

Double-click the region of the new annotation and type 30..46 and press **Enter**. You now have two annotations as shown in figure 2.90.

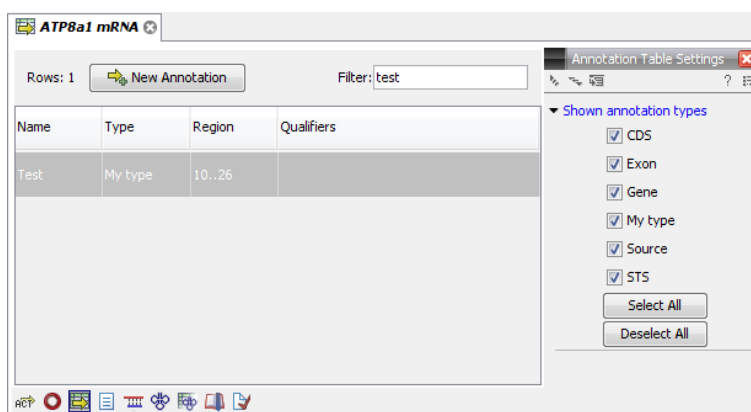

Figure 2.89: The type of the annotation is now My type.

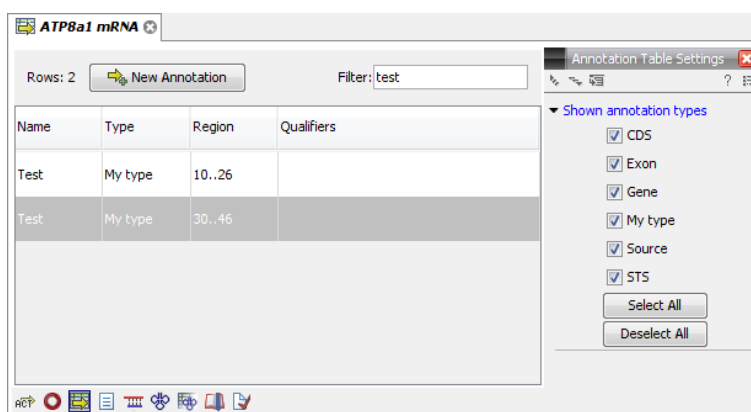

Figure 2.90: Two copies of the Test annotation.

2.15 Tutorial: BLAST Search

BLAST is an invaluable tool in bioinformatics. It has become central to identification of homologues and similar sequences, and can also be used for many other different purposes. This tutorial takes you through the steps of running a blast search in CLC Workbenches. If you plan to use BLAST for your research, we highly recommend that you read further about it. Understanding how BLAST works is key to setting up meaningful and efficient searches.

Suppose you are working with the ATP8a1 protein sequence which is a phospholipid-transporting ATPase expressed in the adult house mouse, *Mus musculus*. To obtain more information about this molecule you wish to query the peptides held in the Swiss-Prot* database to find homologous proteins in humans *Homo sapiens*, using the **Basic Local Alignment Search Tool** (BLAST) algorithm.

This tutorial involves running BLAST remotely using databases housed at the NCBI. Your computer must be connected to the internet to complete this tutorial.

2.15.1 Performing the BLAST search

Start out by:

select protein ATP8a1 | **Toolbox** | **BLAST** (📄) | **BLAST at NCBI** (🌐)

In **Step 1** you can choose which sequence to use as query sequence. Since you have already

chosen the sequence it is displayed in the **Selected Elements** list.

Click **Next**.

In **Step 2** (figure 2.91), choose the default BLAST program: **blastp: Protein sequence and database** and select the **Swiss-Prot** database in the **Database** drop down menu.

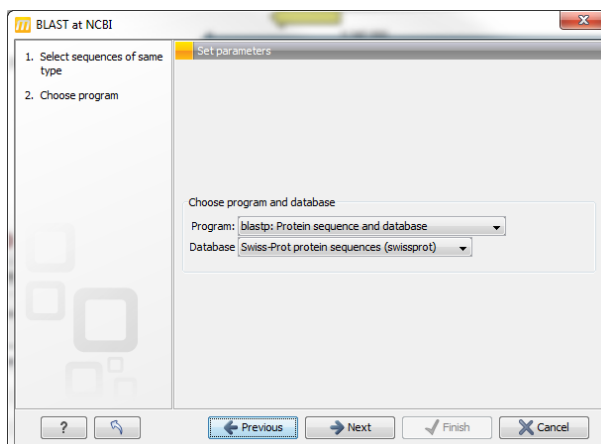

Figure 2.91: Choosing BLAST program and database.

Click **Next**.

In the **Limit by Entrez query** in **Step 3**, choose **Homo sapiens[ORGN]** from the drop down menu to arrive at the search configuration seen in figure 2.92. Including this term limits the query to proteins of human origin.

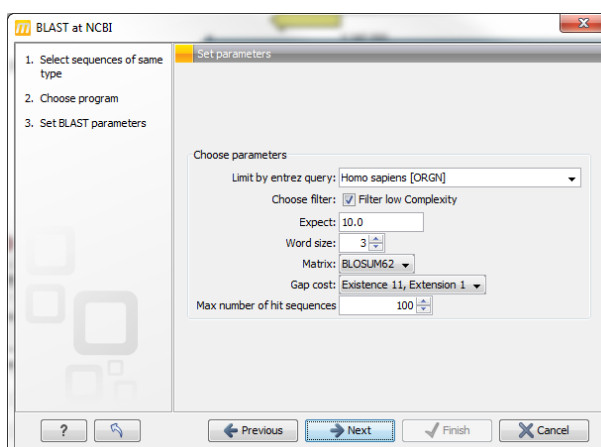

Figure 2.92: The BLAST search is limited to homo sapiens[ORGN]. The remaining parameters are left as default.

Choose to **Open** your results.

Click **Finish** to accept the parameter settings and begin the BLAST search.

The computer now contacts NCBI and places your query in the BLAST search queue. After a short while the result should be received and opened in a new view.

2.15.2 Inspecting the results

The output is shown in figure 2.93 and consists of a list of potential homologs that are sorted by their BLAST match-score and shown in descending order below the query sequence.

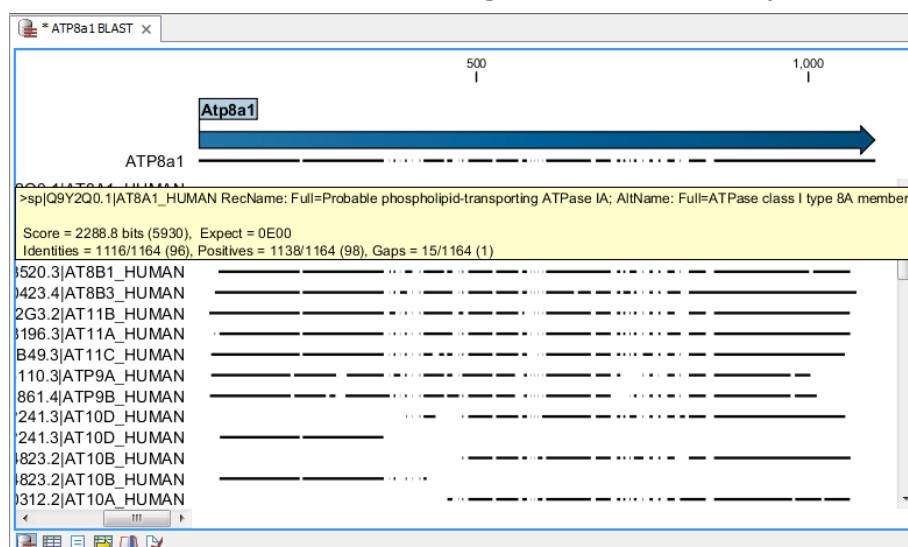

Figure 2.93: Output of a BLAST search. By holding the mouse pointer over the lines you can get information about the sequence.

Try placing your mouse cursor over a potential homologous sequence. You will see that a context box appears containing information about the sequence and the match-scores obtained from the BLAST algorithm.

The lines in the BLAST view are the actual sequences which are downloaded. This means that you can zoom in and see the actual alignment:

Zoom in using the Tool Bar zoom function (🔍) | Click in the BLAST view a number of times until you see the residues

Now we will focus our attention on sequence Q9Y2Q0 - the BLAST hit that is at the top of the list. To download the full sequence:

right-click the line representing sequence Q9Y2Q0 | Download Full Hit Sequence from NCBI

This opens the sequence. However, the sequence is not saved yet. Drag and drop the sequence into the **Navigation Area** to save it. This homologous sequence is now stored in the *CLC Main Workbench* and you can use it to gain information about the query sequence by using the various tools of the workbench, e.g. by studying its textual information, by studying its annotation or by aligning it to the query sequence.

2.15.3 Using the BLAST table view

As an alternative to the graphic BLAST view, you can click the Table View (📄) at the bottom. This will display a tabular view of the BLAST hits as shown in figure 2.94.

This view provides more statistics about the hits, and you can use the filter to search for e.g. a specific type of protein etc. If you wish to download several of the hit sequences, this is easily done in this view. Simply select the relevant sequences and drag them into a folder in the

Hit	Description	E-value	Score
Q9Y2Q0	RecName: Full=Probable phospholipid-transporting ATPase IA; AltName: Full=ATPase class I type 8A member 1; AltNa...	0.00	5,930.00
Q9NTI2	RecName: Full=Probable phospholipid-transporting ATPase IB; AltName: Full=ATPase class I type 8A member 2; AltNa...	0.00	4,147.00

Figure 2.94: Output of a BLAST search shown in a table.

Navigation Area.

2.16 Tutorial: Tips for Specialized BLAST Searches

Here, you will learn how to:

- Use BLAST to find the gene coding for a protein in a genomic sequence.
- Find primer binding sites on genomic sequences
- Identify remote protein homologues.

Following through these sections of the tutorial requires some experience using the Workbench, so if you get stuck at some point, we recommend going through the more basic tutorials first.

2.16.1 Locate a protein sequence on the chromosome

If you have a protein sequence but want to see the actual location on the chromosome this is easy to do using BLAST.

In this example we wish to map the protein sequence of the human arrestin domain-containing protein 5 (ARRDC5) protein to a chromosome. We know in advance that the ARRDC5 is located somewhere on chromosome 19.

Data used in this example can be downloaded from GenBank:

Download | Search for Sequences at NCBI ()

Human chromosome 19 (NC_000019) consists of 59128983 nucleotides and the ARRDC5 (NP_001073992) protein has 342 amino acids.

BLAST configuration

Next, conduct a local BLAST search:

Toolbox | BLAST | BLAST

Select the protein sequence as query sequence and click **Next**. Since you wish to BLAST a protein sequence against a nucleotide sequence, select **tblastn**, which will automatically translate the selected nucleotide sequence to database format.

Select the just downloaded chr19 sequence *NC_000019* as target. If you are used to BLAST, you will know that you usually have to create a BLAST database before BLASTing. However, the Workbench does this "on the fly" when one or more sequences have been selected.

Click **Next**, leave the parameters at their default, click **Next** again, and then **Finish**.

Inspect BLAST result

When the BLAST result appears make a split view so that both the table and graphical view is visible (see figure 2.95). This is done by pressing Ctrl (⌘ on Mac) while clicking the table view  at the bottom of the view.

In the side panel under BLAST table settings, select the same settings as shown in figure 2.95 by checking the relevant parameters under "Show column".

Now, sort the BLAST table view by clicking twice on the column header "% Positive". Then, press and hold the Ctrl button (⌘ on Mac) and click the header "Query start". You have now sorted the table first on % Positive hits and then on the start position of the query sequence. In the table you can see three hits with 97 - 100% positive (=similar residues) at different locations on the chromosome sequence (see figure 2.95).

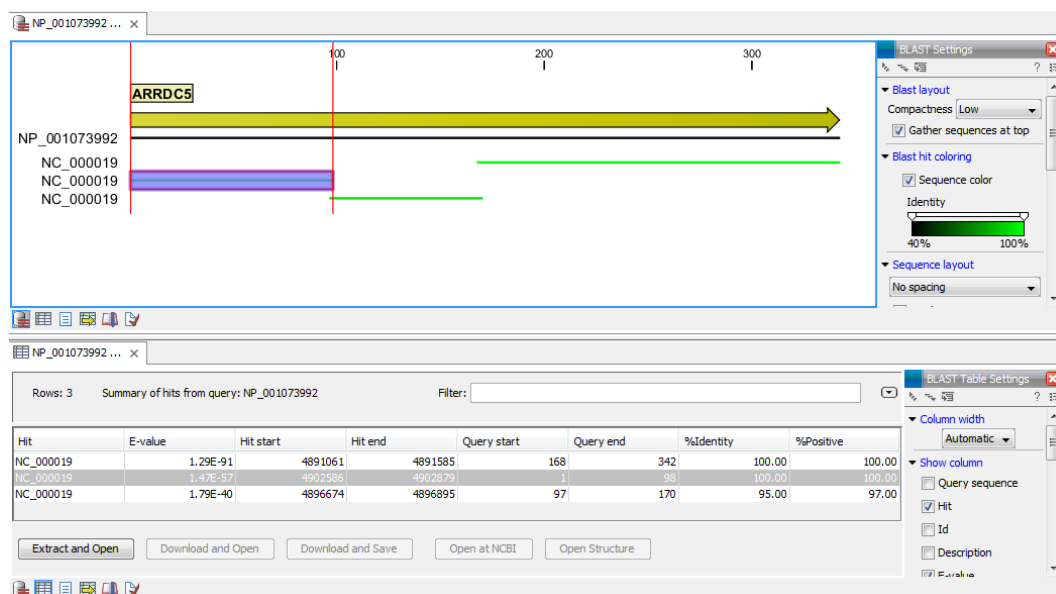

Figure 2.95: Placement of translated nucleotide sequence hits on the Human ARRDC5 protein.

Why did we find, on the protein level, three identical regions between our query protein sequence and nucleotide database?

The ARRDC5 gene is known to have three exons, which is in agreement with the three hits in the BLAST search. Each translated exon will hit the corresponding sequence on the chromosome.

If you place the mouse cursor on the sequence hits in the graphical view, you can see the reading

frame, which is -1, -3 and -3 for the three hits, respectively.

Verify the result

Open NC_0000019 in a view, and go to Hit position (4,902,879) and zoom to see the blue gene annotation. You can now see the exon structure of the ARRDC5 gene showing the three exons on the reverse strand (see figure 2.96).

Figure 2.96: ARRDC5 exon view.

If you wish to verify the result, make a selection covering the gene region and open it in a new view:

right-click | Open Selection in New View (📄+) | Save (💾)

Save the sequence and perform a new BLAST search:

- Use the new sequence as query.
- Use BLASTx
- Use the protein sequence, NP_001073992, as target sequence

Tip: In stead of using the protein sequence NP_001073992 as target sequence you can also use it as database. To do this, you first have to create a database:

Toolbox | BLAST (📄) | Create BLAST database (📄+)

Using the genomic sequence as query, the mapping of the protein sequence to the exons is visually very clear as shown in figure 2.97.

In theory you could use the chromosome sequence as query, but the performance would not be optimal: it would take a long time, and the computer might run out of memory.

In this example you have used well-annotated sequences where you could have searched for the name of the gene instead of using BLAST. However, there are other situations where you either do not know the name of the gene, or the genomic sequence is poorly annotated. In these cases, the approach described in this tutorial can be very productive.

2.16.2 BLAST for primer binding sites

You can adjust the BLAST parameters so it becomes possible to match short primer sequences against a larger sequence. Then it is easy to examine whether already existing lab primers can

Figure 2.97: Verification of the result: at the top a view of the whole BLAST result. At the bottom the same view zoomed in on exon 3 to show the amino acids.

be reused for other purposes, or if the primers you designed are specific.

Purpose	Program	Word size	Low complexity filter	Expect value
Standard BLAST	blastn	11	On	10
Primer search	blastn	7	Off	1000

These settings are shown in figure 2.98.

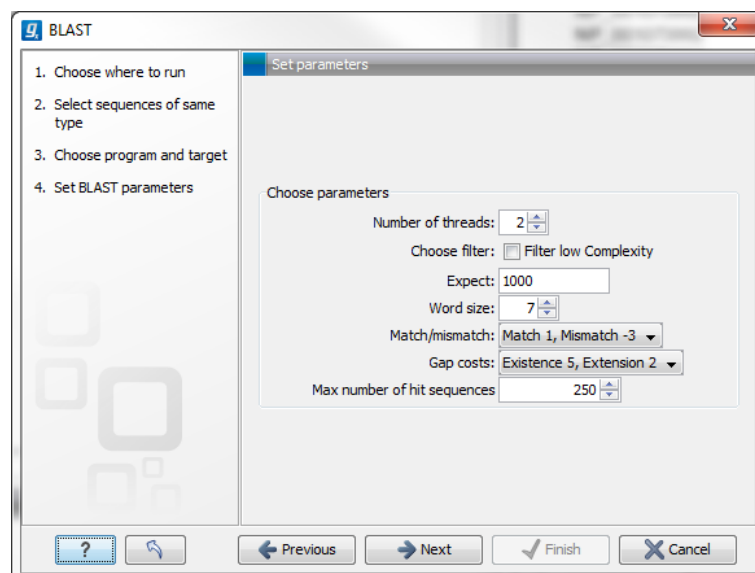

Figure 2.98: Settings for searching for primer binding sites.

2.16.3 Finding remote protein homologues

If you look for short identical peptide sequences in a database, the standard BLAST parameters will have to be reconfigured. Using the parameters described below, you are likely to be able to identify whether antigenic determinants will cross react to other proteins.

Purpose	Program	Word size	Low complexity filter	Expect value	Scoring matrix
Standard BLAST	blastp	3	On	10	BLSUM62
Remote homologues	blastp	2	Off	20000	PAM30

These settings are shown in figure 2.99.

Figure 2.99: Settings for searching for remote homologues.

2.16.4 Further reading

A valuable source of information about BLAST can be found at http://blast.ncbi.nlm.nih.gov/Blast.cgi?CMD=Web&PAGE_TYPE=BlastDocs&DOC_TYPE=ProgSelectionGuide.

Remember that BLAST is a heuristic method. This means that certain assumptions are made to allow searches to be done in a reasonable amount of time. Thus you cannot trust BLAST search results to be accurate. For very accurate results you should consider using other algorithms, such as Smith-Waterman. You can read "Bioinformatics explained: BLAST versus Smith-Waterman" here: <http://www.clcbio.com/BE>.

2.17 Tutorial: Proteolytic Cleavage Detection

This tutorial shows you how to find cut sites and see an overview of fragments when cleaving proteins with proteolytic cleavage enzymes.

Suppose you are working with protein ATP8a1 from the example data, and you wish to see where the enzyme *trypsin* will cleave the protein. Furthermore, you want to see details for the resulting fragments which are between 10 and 15 amino acids long.

select protein ATP8a1 | Toolbox | Protein Analysis () | Proteolytic Cleavage

This opens **Step 1** of the Proteolytic Cleavage dialog. In this step you can choose which sequences to include in the analysis. Since you have already chosen ATP8a1, click **Next**.

In this step you should select **Trypsin**. This is illustrated in figure 2.100.

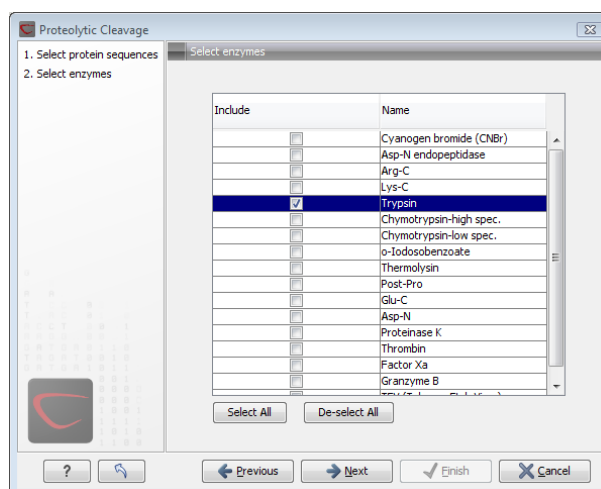

Figure 2.100: Selecting trypsin as the cleaving enzyme.

Click **Next** to go to **Step 3** of the dialog.

In **Step 3** you can adjust the parameters for which fragments of the cleavage you want to include in the table output of the analysis.

Type '10' in the Min. fragment length | Check the box: Max. fragment length | enter '15' in the corresponding text field

These parameter adjustments are shown in figure 2.101:

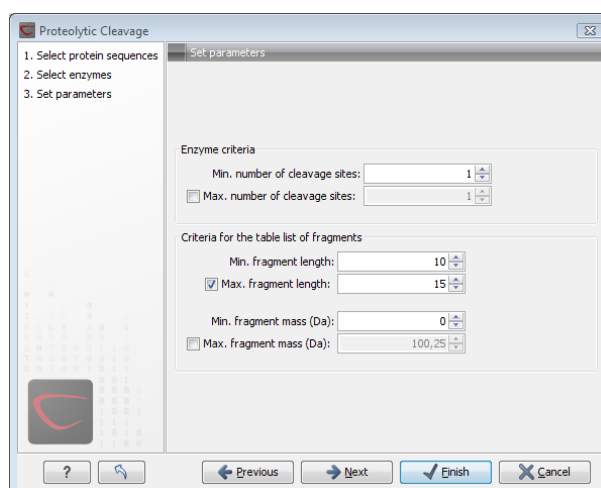

Figure 2.101: Adjusting the output from the cleavage to include fragments which are between 10 and 15 amino acids long.

Click **Finish** to make the analysis. The result of the analysis can be seen in figure 2.102

Note! The output of proteolytic cleavage is two related views. The sequence view displays annotations where the sequence is cleaved. The table view shows information about the fragments satisfying the parameters set in the dialog. Subsequently, if you have restricted the

Figure 2.102: The output of the proteolytic cleavage shows the cleavage sites as annotations in the protein sequence. The accompanying table lists all the fragments which are between 10 and 15 amino acids long.

fragment parameters, you might have more annotations on the sequence than fragments in the table.

If you conduct another proteolytic cleavage on the same sequence, the output consists of: (possibly) new annotations on the original sequence and an additional table view, listing all fragments.

2.18 Tutorial: Folding RNA Molecules

In this tutorial, you will learn how to predict the secondary structure of an RNA molecule. You will also learn how to use the powerful ways of viewing and interacting with graphical displays of the structure.

The sequence to be folded in this tutorial is a tRNA molecule with the characteristic secondary structure as shown in figure 2.103.

Figure 2.103: Secondary structure of a tRNA molecule.

The goal for this tutorial is to get a nice-looking graphic result of this structure.

The sequence we are working with is a mitochondrial tRNA molecule from *Drosophila melanogaster*. The name is AB009835, and can be found by searching GenBank:

This structure does not look like the one we expected (shown in figure 2.103). We now take a look at some of the other structures (we chose to compute 10 different structures) to see if we can find the classic tRNA structure. First, open a split view of the **Show Secondary Structure Table** (🔍):

Press and hold Ctrl (⌘ on Mac) | Show Secondary Structure Table (🔍)

You will now see a table displaying the ten structures. Selecting a structure in the table will display this structure in the view above. Select the second structure in the table. The views should now look like figure 2.107).

The figure shows a software interface with two main panels. The top panel, titled 'Secondary Structure 2D View S...', displays a 2D representation of a tRNA molecule. The molecule is shown as a series of connected circles representing nucleotides, with lines indicating base pairs. The overall structure is a classic tRNA shape. The energy value $\Delta G = -9.7 \text{ kcal/mol}$ is displayed above the structure. The bottom panel shows a table with 22 rows of structure data. The table has columns for Name, Created, ΔG , and Probability. The second row is selected, and its details are shown in a list on the right side of the bottom panel. The list includes elements like 'Stem with bifurcation at 1..70: $\Delta G = -8.6 \text{ kcal/mol}$ ', 'Stem base pairs at join(1..7,64..70): $\Delta G = -9.9 \text{ kcal/mol}$ ', 'Multi loop at 7..64: $\Delta G = 1.3 \text{ kcal/mol}$ ', 'Multi loop base pairs at join(7,64,10,22,25,39,46,63): $\Delta G = -1.1 \text{ kcal/mol}$ ', 'Multi loop arcs at join(8..9,23..24,40..45,63^64): $\Delta G = -1.1 \text{ kcal/mol}$ ', 'Stem with hairpin at 10..22: $\Delta G = 0.2 \text{ kcal/mol}$ ', 'Stem with hairpin at 25..39: $\Delta G = -1.9 \text{ kcal/mol}$ ', and 'Stem with hairpin at 46..63: $\Delta G = -1.4 \text{ kcal/mol}$ '.

Name	Created	ΔG	Probability
$\Delta G = -9.9 \text{ kcal/mol}$	26-11-2007 09:05:59	-9.9kcal/mol	6.69E-3
$\Delta G = -9.7 \text{ kcal/mol}$	26-11-2007 09:05:59	-9.7kcal/mol	4.98E-3
$\Delta G = -9.4 \text{ kcal/mol}$	26-11-2007 09:05:59	-9.4kcal/mol	3.06E-3
$\Delta G = -9.2 \text{ kcal/mol}$	26-11-2007 09:05:59	-9.2kcal/mol	2.21E-3
$\Delta G = -9.1 \text{ kcal/mol}$	26-11-2007 09:05:59	-9.1kcal/mol	1.88E-3
$\Delta G = -9.1 \text{ kcal/mol}$	26-11-2007 09:05:59	-9.1kcal/mol	1.88E-3
$\Delta G = -8.9 \text{ kcal/mol}$	26-11-2007 09:05:59	-8.9kcal/mol	1.36E-3
$\Delta G = -8.6 \text{ kcal/mol}$	26-11-2007 09:05:59	-8.6kcal/mol	8.35E-4
$\Delta G = -8.4 \text{ kcal/mol}$	26-11-2007 09:05:59	-8.4kcal/mol	6.03E-4
$\Delta G = -8.3 \text{ kcal/mol}$	26-11-2007 09:05:59	-8.3kcal/mol	5.13E-4

Figure 2.107: A split view showing the secondary structure table at the bottom and the Secondary structure 2D view at the top. (You might need to Zoom out to see the structure).

The secondary structure now looks very similar to figure 2.103. By adjusting the layout, we can make it look exactly the same: in the Side Panel of the 2D view, under **Secondary Structure**, choose the **Proportional** layout strategy. You will now see that the appearance of structure changes.

Next, zoom in on the structure to see the residues. This is easiest if you first close (✖) the table view at the bottom.

Zoom in (🔍) | Click the structure until you see the residues

If you wish to make some manual corrections of the layout of the structure, first select the **Pan** (🖱) mode in the Tool bar. Now place the mouse cursor on the opening of a stem, and a visual indication of the anchor point for turning the substructure will be shown (see figure 24.14).

Click and drag to rotate the part of the structure represented by the line going from the anchor point. In order to keep the bases in a relatively sequential arrangement, there is a restriction on how much the substructure can be rotated. The highlighted part of the circle represents the angle where rotating is allowed.

In figure 24.15, the structure shown in figure 24.14 has been modified by dragging with the

Figure 2.108: The blue circle represents the anchor point for rotating the substructure.

mouse.

Figure 2.109: The structure has now been rotated.

The view can of course be printed (🖨️) or exported as graphics (🖼️).

2.19 Tutorial: Align Protein Sequences

This tutorial outlines some of the alignment functionality of the *CLC Main Workbench*. In addition to creating alignments of nucleotide or peptide sequences, the software offers several ways to view alignments. The alignments can then be used for building phylogenetic trees.

Sequences must be available via the **Navigation Area** to be included in an alignment. If you have sequences open in a View that you have not saved, then you just need to select the view tab and press Ctrl + S (or ⌘ + S on Mac) to save them.

In this tutorial six protein sequences from the Example data folder will be aligned. (See figure 2.110).

To align the sequences:

Figure 2.110: Six protein sequences in 'Sequences' from the 'Protein orthologs' folder of the Example data.

select the sequences from the 'Protein' folder under 'Sequences' | Toolbox | Alignments and Trees () | Create Alignment ()

2.19.1 The alignment dialog

This opens the dialog shown in figure 2.111.

Figure 2.111: The alignment dialog displaying the six protein sequences.

It is possible to add and remove sequences from **Selected Elements** list. Since we had already selected the eight proteins, just click **Next** to adjust parameters for the alignment.

Clicking **Next** opens the dialog shown in figure 2.112.

Leave the parameters at their default settings. An explanation of the parameters can be found by clicking the help button (?). Alternatively, a tooltip is displayed by holding the mouse cursor on the parameters.

Click **Finish** to start the alignment process which is shown in the **Toolbox** under the **Processes** tab. When the program is finished calculating it displays the alignment (see fig. 2.113):

Note! The new alignment is not saved automatically.

To save the alignment, drag the tab of the alignment view into the **Navigation Area**.

Installing the Additional Alignments plugin gives you access to two other alignment algorithms: ClustalW (Windows/Mac/Linux) and Muscle (Windows/Mac/Linux). The Additional Alignments Module can be downloaded from <http://www.clcbio.com/plugins>. Note that you will need administrative privileges on your system to install it.

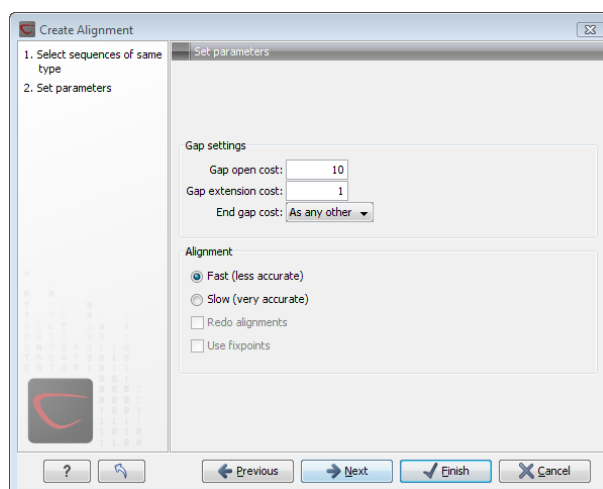

Figure 2.112: The alignment dialog displaying the available parameters which can be adjusted.

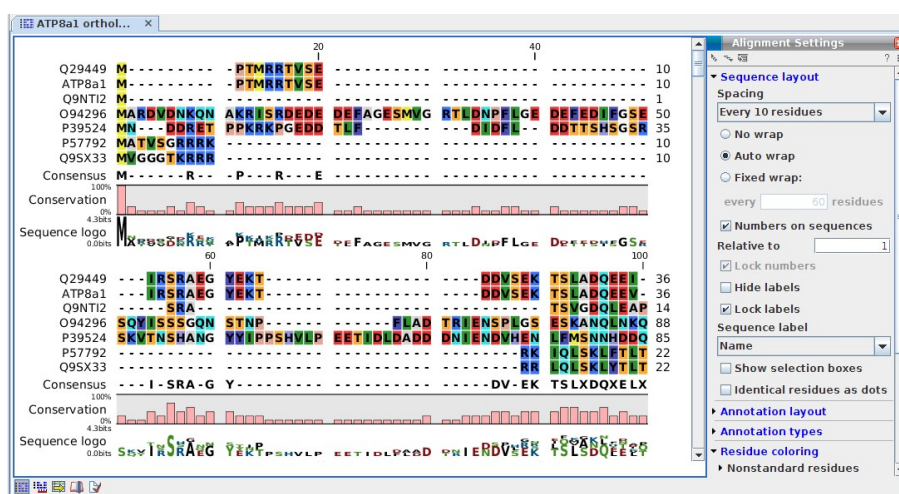

Figure 2.113: The resulting alignment.

2.20 Tutorial: Create and Modify a Phylogenetic Tree

You can make a phylogenetic tree from an existing alignment. (See how to create an alignment in the tutorial: "Align protein sequences").

We use the 'ATPase protein alignment' located in 'Protein orthologs' in the Example data. To create a phylogenetic tree:

click the 'ATPase protein alignment' in the Navigation Area | Toolbox | Alignments and Trees (🗂️) | Create Tree (🌳)

A dialog opens where you can confirm your selection of the alignment. Click **Next** to move to the next step in the dialog where you can choose between the neighbor joining and the UPGMA algorithms for making trees. You also have the option of including a bootstrap analysis of the result. Leave the parameters at their default, and click **Finish** to start the calculation, which can be seen in the **Toolbox** under the **Processes** tab. After a short while a tree appears in the **View Area** (figure 2.114).

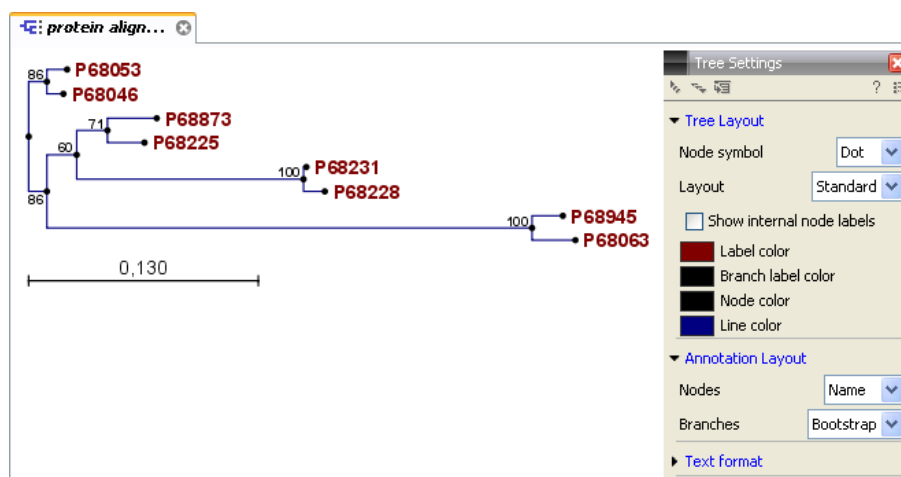

Figure 2.114: After choosing which algorithm should be used, the tree appears in the View Area. The Side panel in the right side of the view allows you to adjust the way the tree is displayed.

2.20.1 Tree layout

Using the **Side Panel** (in the right side of the view), you can change the way the tree is displayed.

Click **Tree Layout** and open the **Layout** drop down menu. Here you can choose between standard and topology layout. The topology layout can help to give an overview of the tree if some of the branches are very short.

When the sequences include the appropriate annotation, it is possible to choose between the accession number and the species names at the leaves of the tree. Sequences downloaded from GenBank, for example, have this information. The **Labels** preferences allows these different node annotations as well as different annotation on the branches.

The branch annotation includes the bootstrap value, if this was selected when the tree was calculated. It is also possible to annotate the branches with their lengths.

2.21 Tutorial: Find Restriction Sites

This tutorial will show you how to find restriction sites and annotate them on a sequence.

There are two ways of finding and showing restriction sites. In many cases, the dynamic restriction sites found in the **Side Panel** of sequence views will be useful, since it is a quick and easy way of showing restriction sites. In the **Toolbox** you will find the other way of doing restriction site analyses. This way provides more control of the analysis and gives you more output options, e.g. a table of restriction sites and a list of restriction enzymes that can be saved for later use. In this tutorial, the first section describes how to use the Side Panel to show restriction sites, whereas the second section describes the restriction map analysis performed from the **Toolbox**.

2.21.1 The Side Panel way of finding restriction sites

When you open a sequence, there is a **Restriction sites** setting in the **Side Panel**. By default, 10 of the most popular restriction enzymes are shown (see figure 2.115).

The restriction sites are shown on the sequence with an indication of cut site and recognition

Figure 2.115: Showing restriction sites of ten restriction enzymes.

sequence. In the list of enzymes in the **Side Panel**, the number of cut sites is shown in parentheses for each enzyme (e.g. *SalI* cuts three times). If you wish to see the recognition sequence of the enzyme, place your mouse cursor on the enzyme in the list for a short moment, and a tool tip will appear.

You can add or remove enzymes from the list by clicking the **Manage enzymes** button.

2.21.2 The Toolbox way of finding restriction sites

Suppose you are working with sequence 'ATP8a1 mRNA' from the example data, and you wish to know which restriction enzymes will cut this sequence exactly once and create a 3' overhang. Do the following:

select the ATP8a1 mRNA sequence | Toolbox in the Menu Bar | Cloning and Restriction Sites (🔧) | Restriction Site Analysis (✂️)

Click **Next** to set parameters for the restriction map analysis.

In this step first select **Use existing enzyme list** and click the **Browse for enzyme list** button (🔍). Select the 'Popular enzymes' in the Cloning folder under Enzyme lists.

Then write 3' into the filter below to the left. Select all the enzymes and click the **Add** button (➡️). The result should be like in figure 2.116.

Click **Next**. In this step you specify that you want to show enzymes that cut the sequence only once. This means that you should de-select the **Two restriction sites** checkbox.

Click **Next** and select that you want to **Add restriction sites as annotations on sequence** and **Create restriction map**. (See figure 2.117).

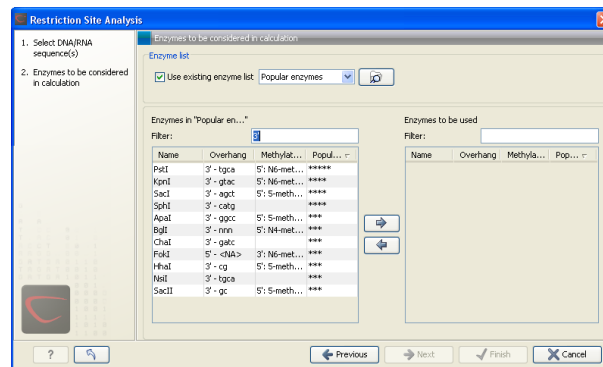

Figure 2.116: Selecting enzymes.

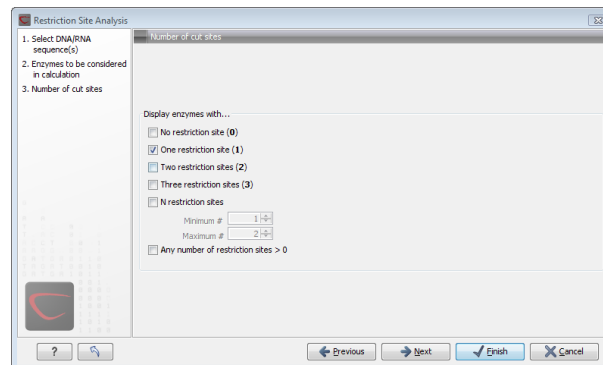

Figure 2.117: Selecting output for restriction map analysis.

Click **Finish** to start the restriction map analysis.

View restriction site

The restriction sites are shown in two views: one view is in a tabular format and the other view displays the sites as annotations on the sequence.

The result is shown in figure 2.118. The restriction map at the bottom can also be shown as a table of fragments produced by cutting the sequence with the enzymes:

Click the Fragments button () at the bottom of the view

In a similar way the fragments can be shown on a virtual gel:

Click the Gel button () at the bottom of the view

Figure 2.118: The result of the restriction map analysis is displayed in a table at the bottom and as annotations on the sequence in the view at the top.

Part II

Core Functionalities

Chapter 3

User interface

3.4.2 Select Workspace	125
3.4.3 Delete Workspace	126
3.5 List of shortcuts	126

This chapter provides an overview of the different areas in the user interface of *CLC Main Workbench*. As can be seen from figure 3.1 this includes a **Navigation Area, View Area, Menu Bar, Toolbar, Status Bar** and **Toolbox**.

A description of the **Navigation Area** is tightly connected to the data management features of *CLC Main Workbench* and can be found in section 4.1.

Figure 3.1: The user interface consists of the Menu Bar, Toolbar, Status Bar, Navigation Area, Toolbox, and View Area.

3.1 View Area

The **View Area** is the right-hand part of the screen, displaying your current work. The **View Area** may consist of one or more **Views**, represented by tabs at the top of the **View Area**.

This is illustrated in figure 3.2.

Figure 3.2: A View Area can enclose several views, each view is indicated with a tab (see right view, which shows protein P68225). Furthermore, several views can be shown at the same time (in this example, four views are displayed).

The tab concept is central to working with *CLC Main Workbench*, because several operations can be performed by dragging the tab of a view, and extended right-click menus can be activated from

the tabs.

This chapter deals with the handling of views inside a **View Area**. Furthermore, it deals with rearranging the views.

Section 3.2 deals with the zooming and selecting functions.

3.1.1 Open view

Opening a view can be done in a number of ways:

double-click an element in the Navigation Area

or **select an element in the Navigation Area | File | Show | Select the desired way to view the element**

or **select an element in the Navigation Area | Ctrl + O (⌘ + B on Mac)**

Opening a view while another view is already open, will show the new view in front of the other view. The view that was already open can be brought to front by clicking its tab.

Note! If you right-click an open tab of any element, click **Show**, and then choose a different view of the same element, this new view is automatically opened in a split-view, allowing you to see both views.

See section 4.1.5 for instructions on how to open a view using drag and drop.

3.1.2 Show element in another view

Each element can be shown in different ways. A sequence, for example, can be shown as linear, circular, text etc.

In the following example, you want to see a sequence in a circular view. If the sequence is already open in a view, you can change the view to a circular view:

Click Show As Circular (○) at the lower left part of the view

The buttons used for switching views are shown in figure 3.3).

Figure 3.3: The buttons shown at the bottom of a view of a nucleotide sequence. You can click the buttons to change the view to e.g. a circular view or a history view.

If the sequence is already open in a linear view (ACT), and you wish to see both a circular and a linear view, you can split the views very easily:

Press Ctrl (⌘ on Mac) while you | Click Show As Circular (○) at the lower left part of the view

This will open a split view with a linear view at the bottom and a circular view at the top (see 11.5).

You can also show a circular view of a sequence without opening the sequence first:

Select the sequence in the Navigation Area | Show (📄) | As Circular (○)

3.1.3 Close views

When a view is closed, the **View Area** remains open as long as there is at least one open view.

A view is closed by:

right-click the tab of the View | Close

or **select the view | Ctrl + W**

or **hold down the Ctrl-button | Click the tab of the view while the button is pressed**

By right-clicking a tab, the following close options exist. See figure 3.4

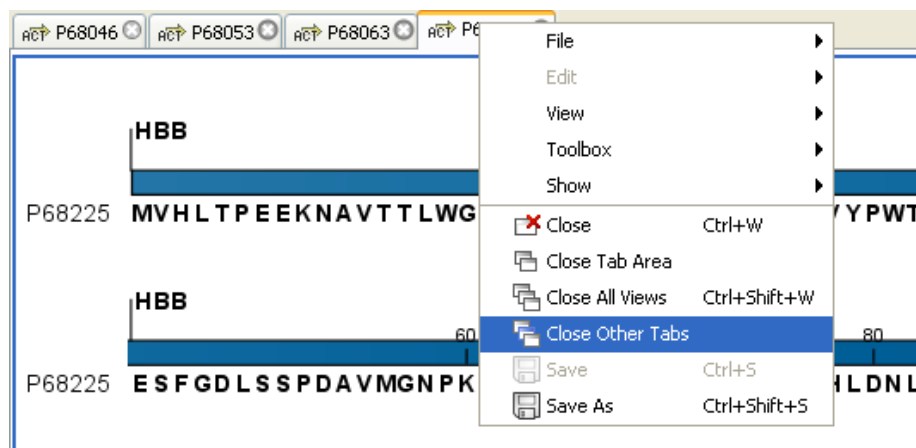

Figure 3.4: By right-clicking a tab, several close options are available.

- **Close.** See above.
- **Close Tab Area.** Closes all tabs in the tab area.
- **Close All Views.** Closes all tabs, in all tab areas. Leaves an empty workspace.
- **Close Other Tabs.** Closes all other tabs, in all tab areas, except the one that is selected.

3.1.4 Save changes in a view

When changes are made in a view, the text on the tab appears *bold and italic* (on Mac it is indicated by an * before the name of the tab). This indicates that the changes are not saved. The **Save** function may be activated in two ways:

Click the tab of the view you want to save | Save (📁) in the toolbar.

or **Click the tab of the view you want to save | Ctrl + S (⌘ + S on Mac)**

If you close a view containing an element that has been changed since you opened it, you are asked if you want to save.

When saving a new view that has not been opened from the Navigation Area (e.g. when opening a sequence from a list of search hits), a save dialog appears (figure 3.5).

In the dialog you select the folder in which you want to save the element.

After naming the element, press **OK**

Figure 3.5: Save dialog.

3.1.5 Undo/Redo

If you make a change in a view, e.g. remove an annotation in a sequence or modify a tree, you can undo the action. In general, **Undo** applies to all changes you can make when right-clicking in a view. **Undo** is done by:

Click undo (↶) in the Toolbar

or **Edit | Undo (↶)**

or **Ctrl + Z**

If you want to undo several actions, just repeat the steps above. To reverse the undo action:

Click the redo icon in the Toolbar

or **Edit | Redo (↷)**

or **Ctrl + Y**

Note! Actions in the **Navigation Area**, e.g. renaming and moving elements, cannot be undone. However, you can restore deleted elements (see section 4.1.7).

You can set the number of possible undo actions in the Preferences dialog (see section 5).

3.1.6 Arrange views in View Area

Views are arranged in the **View Area** by their tabs. The order of the **views** can be changed using drag and drop. E.g. drag the tab of one view onto the tab of another. The tab of the first view is now placed at the right side of the other tab.

If a tab is dragged into a view, an area of the view is made gray (see fig. 3.6) illustrating that the view will be placed in this part of the **View Area**.

The results of this action is illustrated in figure 3.7.

You can also split a **View Area** horizontally or vertically using the menus.

Splitting horizontally may be done this way:

right-click a tab of the view | View | Split Horizontally (≡)

Figure 3.6: When dragging a view, a gray area indicates where the view will be shown.

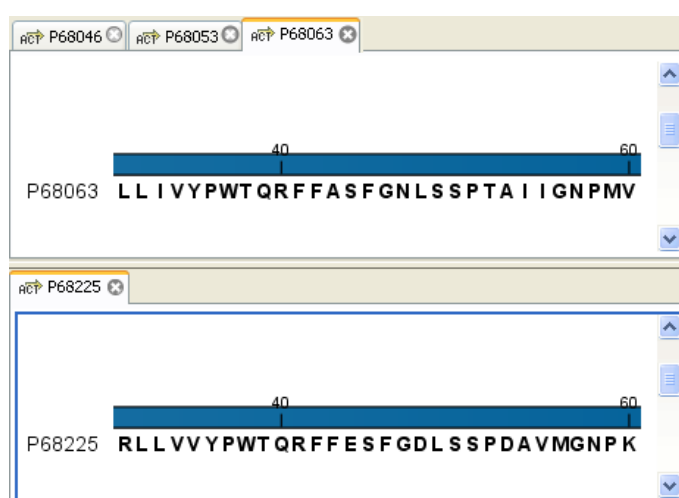

Figure 3.7: A horizontal split-screen. The two views split the View Area.

This action opens the chosen view below the existing view. (See figure 3.8). When the split is made vertically, the new view opens to the right of the existing view.

Splitting the **View Area** can be undone by dragging e.g. the tab of the bottom view to the tab of the top view. This is marked by a gray area on the top of the view.

Maximize/Restore size of view

The **Maximize/Restore View** function allows you to see a view in maximized mode, meaning a mode where no other **views** nor the **Navigation Area** is shown.

Maximizing a view can be done in the following ways:

select view | Ctrl + M

or **select view | View | Maximize/restore View** ()

or **select view | right-click the tab | View | Maximize/restore View** ()

or **double-click the tab of view**

Figure 3.8: A vertical split-screen.

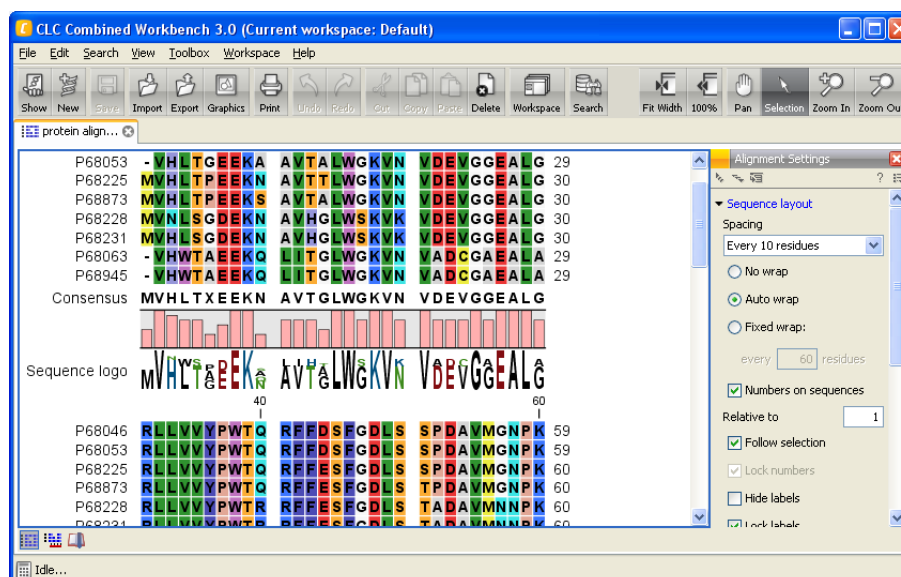

Figure 3.9: A maximized view. The function hides the Navigation Area and the Toolbox.

The following restores the size of the view:

Ctrl + M

or **View | Maximize/restore View** (☐)

or **double-click title of view**

3.1.7 Side Panel

The **Side Panel** allows you to change the way the contents of a view are displayed. The options in the **Side Panel** depend on the kind of data in the view, and they are described in the relevant sections about sequences, alignments, trees etc.

Side Panel are activated in this way:

select the view | Ctrl + U (⌘ + U on Mac)

or **right-click the tab of the view | View | Show/Hide Side Panel** (🔍)

Note! Changes made to the **Side Panel** will not be saved when you save the view. See how to save the changes in the **Side Panel** in chapter 5 .

The **Side Panel** consists of a number of groups of preferences (depending on the kind of data being viewed), which can be expanded and collapsed by clicking the header of the group. You can also expand or collapse all the groups by clicking the icons (🔍)/ (🔍) at the top.

3.2 Zoom and selection in View Area

The mode toolbar items in the right side of the **Toolbar** apply to the function of the mouse pointer. When e.g. **Zoom Out** is selected, you zoom out each time you click in a view where zooming is relevant (texts, tables and lists cannot be zoomed). The chosen mode is active until another mode toolbar item is selected. (**Fit Width** and **Zoom to 100%** do not apply to the mouse pointer.)

Figure 3.10: The mode toolbar items.

3.2.1 Zoom In

There are four ways of **Zooming In**:

Click Zoom In (🔍) in the toolbar | **click the location in the view that you want to zoom in on**

or **Click Zoom In** (🔍) in the toolbar | **click-and-drag a box around a part of the view | the view now zooms in on the part you selected**

or **Press '+' on your keyboard**

The last option for zooming in is only available if you have a mouse with a scroll wheel:

or **Press and hold Ctrl** (⌘ on Mac) | **Move the scroll wheel on your mouse forward**

When you choose the Zoom In mode, the mouse pointer changes to a magnifying glass to reflect the mouse mode.

Note! You might have to click in the view before you can use the keyboard or the scroll wheel to zoom.

If you press the **Shift** button on your keyboard while clicking in a **View**, the zoom function is reversed. Hence, clicking on a sequence in this way while the **Zoom In** mode toolbar item is selected, zooms out instead of zooming in.

3.2.2 Zoom Out

It is possible to zoom out, step by step, on a sequence:

Click Zoom Out () **in the toolbar** | **click in the view until you reach a satisfying zoomlevel**

or **Press '-' on your keyboard**

The last option for zooming out is only available if you have a mouse with a scroll wheel:

or **Press and hold Ctrl** () **on Mac** | **Move the scroll wheel on your mouse backwards**

When you choose the Zoom Out mode, the mouse pointer changes to a magnifying glass to reflect the mouse mode.

Note! You might have to click in the view before you can use the keyboard or the scroll wheel to zoom.

If you want to get a quick overview of a sequence or a tree, use the **Fit Width** function instead of the **Zoom Out** function.

If you press **Shift** while clicking in a **View**, the zoom function is reversed. Hence, clicking on a sequence in this way while the **Zoom Out** mode toolbar item is selected, zooms in instead of zooming out.

3.2.3 Fit Width

The **Fit Width** () function adjusts the content of the **View** so that both ends of the sequence, alignment, or tree is visible in the **View** in question. (This function does not change the mode of the mouse pointer.)

3.2.4 Zoom to 100%

The **Zoom to 100%** () function zooms the content of the **View** so that it is displayed with the highest degree of detail. (This function does not change the mode of the mouse pointer.)

3.2.5 Move

The Move mode allows you to drag the content of a **View**. E.g. if you are studying a sequence, you can click anywhere in the sequence and hold the mouse button. By moving the mouse you move the sequence in the **View**.

3.2.6 Selection

The Selection mode () is used for selecting in a **View** (selecting a part of a sequence, selecting nodes in a tree etc.). It is also used for moving e.g. branches in a tree or sequences in an alignment.

When you make a selection on a sequence or in an alignment, the location is shown in the bottom right corner of the screen. E.g. '23~24' means that the selection is between two residues. '23' means that the residue at position 23 is selected, and finally '23..25' means that 23, 24 and 25 are selected. By holding ctrl /  you can make multiple selections.

3.2.7 Changing compactness

There is a shortcut way of changing the compactness setting for read mappings:

or **Press and hold Alt key | Scroll using your mouse wheel or touchpad**

3.3 Toolbox and Status Bar

The **Toolbox** is placed in the left side of the user interface of *CLC Main Workbench* below the **Navigation Area**.

The **Toolbox** shows a **Processes tab** and a **Toolbox tab**.

3.3.1 Processes

By clicking the **Processes** tab, the **Toolbox** displays previous and running processes, e.g. an NCBI search or a calculation of an alignment. The running processes can be stopped, paused, and resumed by clicking the small icon (☐) next to the process (see figure 3.11).

Running and paused processes are not deleted.

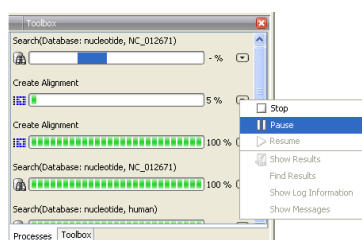

Figure 3.11: A database search and an alignment calculation are running. Clicking the small icon next to the process allow you to stop, pause and resume processes.

Besides the options to stop, pause and resume processes, there are some extra options for a selected number of the tools running from the Toolbox:

- **Show results.** If you have chosen to save the results (see section 9.2), you will be able to open the results directly from the process by clicking this option.
- **Find results.** If you have chosen to save the results (see section 9.2), you will be able to high-light the results in the Navigation Area.
- **Show Log Information.** This will display a log file showing progress of the process. The log file can also be shown by clicking **Show Log** in the "handle results" dialog where you choose between saving and opening the results.
- **Show Messages.** Some analyses will give you a message when processing your data. The messages are the black dialogs shown in the lower left corner of the Workbench that disappear after a few seconds. You can reiterate the messages that have been shown by clicking this option.

The terminated processes can be removed by:

View | Remove Terminated Processes (X)

If you close the program while there are running processes, a dialog will ask if you are sure that you want to close the program. Closing the program will stop the process, and it cannot be restarted when you open the program again.

3.3.2 Toolbox

The content of the **Toolbox** tab in the **Toolbox** corresponds to **Toolbox** in the **Menu Bar**.

The **Toolbox** can be hidden, so that the **Navigation Area** is enlarged and thereby displays more elements:

View | Show/Hide Toolbox

The tools in the toolbox can be accessed by double-clicking or by dragging elements from the **Navigation Area** to an item in the **Toolbox**.

Quick access to tools

To enable quick launch of tools in *CLC Main Workbench*, press Ctrl + Shift + T (⌘ + Shift + T on Mac) to show the quick launch dialog (see figure 3.12).

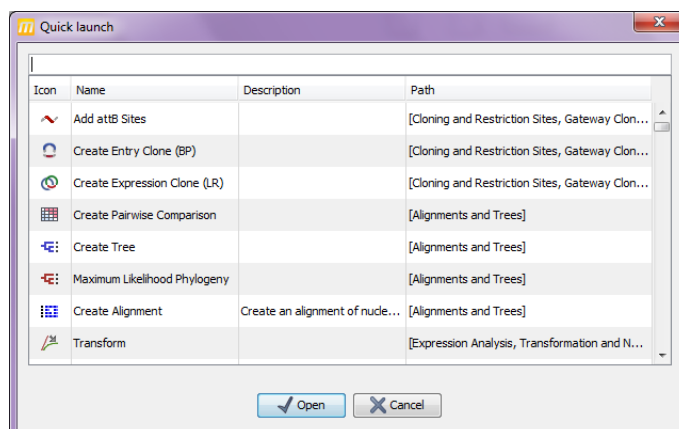

Figure 3.12: Quick access to all tools in **CLC Main Workbench**.

When the dialog is opened, you can start typing search text in the text field at the top. This will bring up the list of tools that match this text either in the name, description or location in the Toolbox. In the example shown in figure 3.13, typing `plot` shows a list of tools involving plots, and the arrow keys or mouse can be used for selecting and starting a tool.

Favorites toolbox

Next to the **Toolbox** tab, you find the **Favorites** tab. This can be used for organizing and getting quick access to the tools you use the most. It consists of two parts as shown in figure 3.14.

Favorites You can manually add tools to the favorites menu simply by right-clicking the tool in the Toolbox. You can also right-click the Favorites folder itself and select **Add Tool**. To remove a tool, right-click and select **Remove from Favorites**. Note that you can also add complete folders to the favorites.

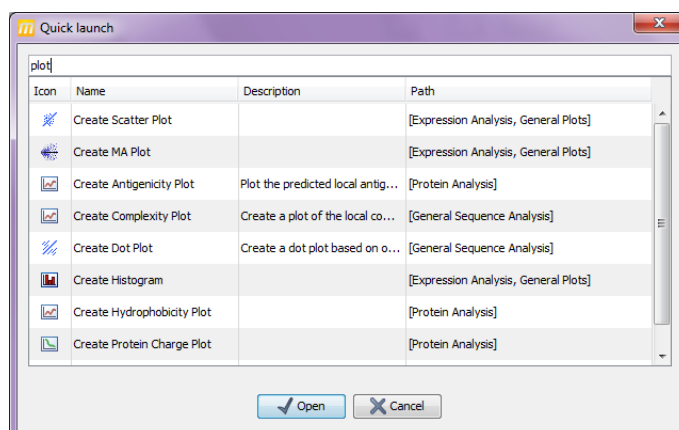

Figure 3.13: Typing in the search field at the top will filter the list of tools to launch.

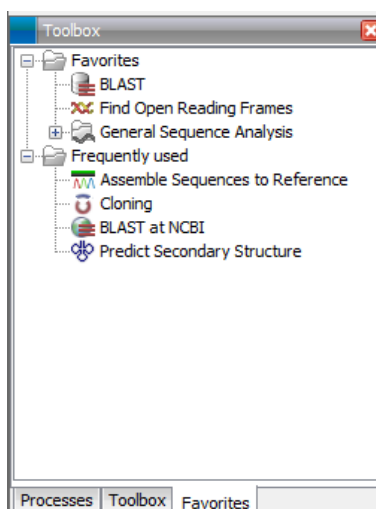

Figure 3.14: Favorites toolbox.

Frequently used The list of tools in this folder is automatically populated as you use the Workbench. The most frequently used tools are listed at the top.

3.3.3 Status Bar

As can be seen from figure 3.1, the **Status Bar** is located at the bottom of the window. In the left side of the bar is an indication of whether the computer is making calculations or whether it is idle. The right side of the **Status Bar** indicates the range of the selection of a sequence. (See chapter 3.2.6 for more about the Selection mode button.)

3.4 Workspace

If you are working on a project and have arranged the views for this project, you can save this arrangement using **Workspaces**. A Workspace remembers the way you have arranged the views, and you can switch between different workspaces.

The **Navigation Area** always contains the same data across **Workspaces**. It is, however, possible to open different folders in the different **Workspaces**. Consequently, the program allows you to display different clusters of the data in separate **Workspaces**.

All **Workspaces** are automatically saved when closing down *CLC Main Workbench*. The next time you run the program, the **Workspaces** are reopened exactly as you left them.

Note! It is not possible to run more than one version of *CLC Main Workbench* at a time. Use two or more **Workspaces** instead.

3.4.1 Create Workspace

When working with large amounts of data, it might be a good idea to split the work into two or more **Workspaces**. As default the *CLC Main Workbench* opens one **Workspace**. Additional **Workspaces** are created in the following way:

Workspace in the Menu Bar | **Create Workspace** | **enter name of Workspace** | **OK**

When the new **Workspace** is created, the heading of the program frame displays the name of the new **Workspace**. Initially, the selected elements in the **Navigation Area** is collapsed and the **View Area** is empty and ready to work with. (See figure 3.15).

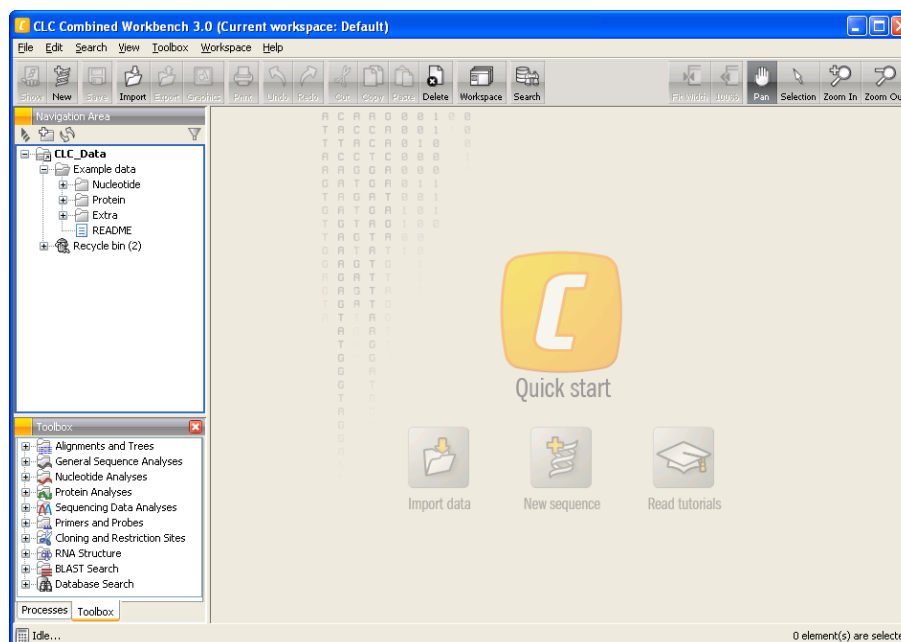

Figure 3.15: An empty Workspace.

3.4.2 Select Workspace

When there is more than one **Workspace** in the *CLC Main Workbench*, there are two ways to switch between them:

Workspace () in the **Toolbar** | **Select the Workspace to activate**

or **Workspace in the Menu Bar** | **Select Workspace** () | **choose which Workspace to activate** | **OK**

The name of the selected **Workspace** is shown after "*CLC Main Workbench*" at the top left corner of the main window, in figure 3.15 it says: (default).

3.4.3 Delete Workspace

Deleting a **Workspace** can be done in the following way:

Workspace in the Menu Bar | Delete Workspace | choose which Workspace to delete | OK

Note! Be careful to select the right **Workspace** when deleting. The delete action cannot be undone. (However, no data is lost, because a workspace is only a representation of data.)

It is not possible to delete the default workspace.

3.5 List of shortcuts

The keyboard shortcuts in *CLC Main Workbench* are listed below.

Action	Windows/Linux	Mac OS X
Adjust selection	Shift + arrow keys	Shift + arrow keys
Change between tabs ¹	Ctrl + tab	Ctrl + Page Up/Down
Close	Ctrl + W	⌘ + W
Close all views	Ctrl + Shift + W	⌘ + Shift + W
Copy	Ctrl + C	⌘ + C
Cut	Ctrl + X	⌘ + X
Delete	Delete	Delete or ⌘ + Backspace
Exit	Alt + F4	⌘ + Q
Export	Ctrl + E	⌘ + E
Export graphics	Ctrl + G	⌘ + G
Find Next Conflict	Space or .	Space or .
Find Previous Conflict	,	,
Help	F1	F1
Import	Ctrl + I	⌘ + I
Maximize/restore size of View	Ctrl + M	⌘ + M
Move gaps in alignment	Ctrl + arrow keys	⌘ + arrow keys
Navigate sequence views	arrow keys	arrow keys
New Folder	Ctrl + Shift + N	⌘ + Shift + N
New Sequence	Ctrl + N	⌘ + N
View	Ctrl + O	⌘ + O
Paste	Ctrl + V	⌘ + V
Print	Ctrl + P	⌘ + P
Redo	Ctrl + Y	⌘ + Y
Rename	F2	F2
Reverse Complement	Ctrl + R	⌘ + R
Save	Ctrl + S	⌘ + S
Search local data	Ctrl + F	⌘ + F
Search within a sequence	Ctrl + Shift + F	⌘ + Shift + F
Search NCBI	Ctrl + B	⌘ + B
Search UniProt	Ctrl + Shift + U	⌘ + Shift + U
Select All	Ctrl + A	⌘ + A
Selection Mode	Ctrl + 2	⌘ + 2
Show/hide Side Panel	Ctrl + U	⌘ + U
Sort folder	Ctrl + Shift + R	⌘ + Shift + R
Split Horizontally	Ctrl + T	⌘ + T
Split Vertically	Ctrl + J	⌘ + J
Start Tool Dialog	Ctrl + Shift + T	⌘ + Shift + T
Translate to Protein	Ctrl + Shift + P	⌘ + Shift + P
Undo	Ctrl + Z	⌘ + Z
User Preferences	Ctrl + K	⌘ + ;
Vertical pan in graph tracks	Alt + drag	Alt + drag
Vertical scroll in read tracks	Alt + Scroll wheel	Alt + Scroll wheel
Vertical scroll in reads tracks, fast	Shift+Alt+Scroll wheel	Shift+Alt+Scroll wheel
Vertical zoom in graph tracks	Alt + Scroll wheel	Alt + Scroll wheel
Zoom	Ctrl + Scroll wheel	Ctrl + Scroll wheel
Zoom In Mode	Ctrl + + (plus)	⌘ + 3
Zoom In (without clicking)	+ (plus)	+ (plus)
Zoom Out Mode	Ctrl + - (minus)	⌘ + 4
Zoom Out (without clicking)	- (minus)	- (minus)
Zoom mode inverse	press and hold Shift	press and hold Shift

¹On Linux changing tabs is accomplished using Ctrl + Page Up/Page Down

Combinations of keys and mouse movements are listed below.

Action	Windows/Linux	Mac OS X	Mouse movement
Maximize View			Double-click the tab of the View
Restore View			Double-click the View title
Reverse zoom function	Shift	Shift	Click in view
Select multiple elements	Ctrl	⌘	Click elements
Select multiple elements	Shift	Shift	Click elements

ements" in this context refers to elements and folders in the **Navigation Area** selections on sequences, and rows in tables.

4.4.2	Quick search	143
4.4.3	Advanced search	145
4.4.4	Search index	148

This chapter explains the data management features of *CLC Main Workbench*. The first section explains the basics of the data organization and the **Navigation Area**. The next section explains how to set up custom attributes for the data that can be used for more advanced data management. Finally, there is a section about how to search through local data.

4.1 Navigation Area

The **Navigation Area** is located in the left side of the screen, under the **Toolbar** (see figure 4.1). It is used for organizing and navigating data. Its behavior is similar to the way files and folders are usually displayed on your computer.

Figure 4.1: The Navigation Area.

4.1.1 Data structure

The data in the **Navigation Area** is organized into a number of **Locations**. When the *CLC Main Workbench* is started for the first time, there is one location called *CLC_Data* (unless your computer administrator has configured the installation otherwise).

A location represents a folder on the computer: The data shown under a location in the **Navigation Area** is stored on the computer in the folder which the location points to.

This is explained visually in figure 4.2.

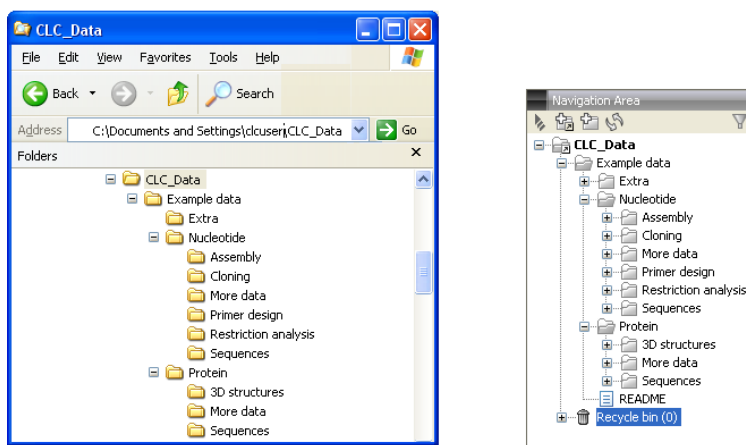

Figure 4.2: In this example the location called 'CLC_Data' points to the folder at *C:\Documents and settings\clcuser\CLC_Data*.

Adding locations

Per default, there is one location in the **Navigation Area** called *CLC_Data*. It points to the following folder:

- On Windows: C:\Documents and settings\\CLC_Data
- On Mac: ~/CLC_Data
- On Linux: /homefolder/CLC_Data

You can easily add more locations to the **Navigation Area**:

File | New | Location (📁)

This will bring up a dialog where you can navigate to the folder you wish to use as your new location (see figure 4.3).

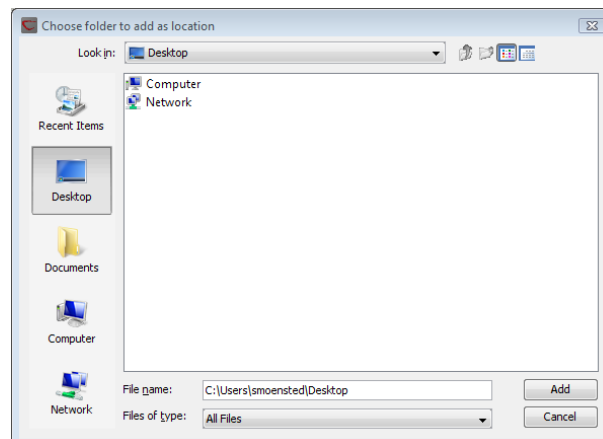

Figure 4.3: Navigating to a folder to use as a new location.

When you click **Open**, the new location is added to the **Navigation Area** as shown in figure 4.4.

Figure 4.4: The new location has been added.

The name of the new location will be the name of the folder selected for the location. To see where the folder is located on your computer, place your mouse cursor on the location icon (📁) for second. This will show the path to the location.

Sharing data is possible if you add a location on a network drive. The procedure is similar to the one described above. When you add a location on a network drive or a removable drive, the location will appear *inactive* when you are not connected. Once you connect to the drive again, click **Update All** (🔄) and it will become active (note that there will be a few seconds' delay from you connect).

Opening data

The elements in the **Navigation Area** are opened by :

Double-click the element

or **Click the element | Show () in the Toolbar | Select the desired way to view the element**

This will open a view in the **View Area**, which is described in section [3.1](#).

Adding data

Data can be added to the **Navigation Area** in a number of ways. Files can be imported from the file system (see chapter [7](#)). Furthermore, an element can be added by dragging it into the **Navigation Area**. This could be views that are open, elements on lists, e.g. search hits or sequence lists, and files located on your computer. Finally, you can add data by adding a new location (see section [4.1.1](#)).

If a file or another element is dropped on a folder, it is placed at the bottom of the folder. If it is dropped on another element, it will be placed just below that element.

If the element already exists in the **Navigation Area**, you will be asked whether you wish to create a copy.

4.1.2 Create new folders

In order to organize your files, they can be placed in folders. Creating a new folder can be done in two ways:

right-click an element in the Navigation Area | New | Folder ()

or **File | New | Folder ()**

If a folder is selected in the **Navigation Area** when adding a new folder, the new folder is added at the bottom of this folder. If an element is selected, the new folder is added right above that element.

You can move the folder manually by selecting it and dragging it to the desired destination.

4.1.3 Sorting folders

You can sort the elements in a folder alphabetically:

right-click the folder | Sort Folder

On Windows, subfolders will be placed at the top of the folder, and the rest of the elements will be listed below in alphabetical order. On Mac, both subfolders and other elements are listed together in alphabetical order.

4.1.4 Multiselecting elements

Multiselecting elements means that you select more than one element at the same time. This can be done in the following ways:

- Holding down the <Ctrl> key (⌘ on Mac) while clicking on multiple elements selects the elements that have been clicked.

- Selecting one element, and selecting another element while holding down the <Shift> key selects all the elements listed between the two locations (the two end locations included).
- Selecting one element, and moving the cursor with the arrow-keys while holding down the <Shift> key, enables you to increase the number of elements selected.

4.1.5 Moving and copying elements

Elements can be moved and copied in several ways:

- Using **Copy** () , **Cut** () and **Paste** () from the **Edit** menu.
- Using Ctrl + C ($\text{⌘} + C$ on Mac), Ctrl + X ($\text{⌘} + X$ on Mac) and Ctrl + V ($\text{⌘} + V$ on Mac).
- Using **Copy** () , **Cut** () and **Paste** () in the **Toolbar**.
- Using drag and drop to move elements.
- Using drag and drop while pressing Ctrl / Command to copy elements.

In the following, all of these possibilities for moving and copying elements are described in further detail.

Copy, cut and paste functions

Copies of elements and folders can be made with the copy/paste function which can be applied in a number of ways:

select the files to copy | right-click one of the selected files | Copy () | right-click the location to insert files into | Paste ()

or **select the files to copy | Ctrl + C ($\text{⌘} + C$ on Mac) | select where to insert files | Ctrl + P ($\text{⌘} + P$ on Mac)**

or **select the files to copy | Edit in the Menu Bar | Copy () | select where to insert files | Edit in the Menu Bar | Paste ()**

If there is already an element of that name, the pasted element will be renamed by appending a number at the end of the name.

Elements can also be moved instead of copied. This is done with the cut/paste function:

select the files to cut | right-click one of the selected files | Cut () | right-click the location to insert files into | Paste ()

or **select the files to cut | Ctrl + X ($\text{⌘} + X$ on Mac) | select where to insert files | Ctrl + V ($\text{⌘} + V$ on Mac)**

When you have cut the element, it is "greyed out" until you activate the paste function. If you change your mind, you can revert the cut command by copying another element.

Note that if you move data between locations, the original data is kept. This means that you are essentially doing a copy instead of a move operation.

Move using drag and drop

Using drag and drop in the **Navigation Area**, as well as in general, is a four-step process:

click the element | click on the element again, and hold left mouse button | drag the element to the desired location | let go of mouse button

This allows you to:

- Move elements between different folders in the **Navigation Area**
- Drag from the **Navigation Area** to the **View Area**: A new view is opened in an existing **View Area** if the element is dragged from the **Navigation Area** and dropped next to the tab(s) in that **View Area**.
- Drag from the **View Area** to the **Navigation Area**: The element, e.g. a sequence, alignment, search report etc. is saved where it is dropped. If the element already exists, you are asked whether you want to save a copy. You drag from the **View Area** by dragging the tab of the desired element.

Use of drag and drop is supported throughout the program, also to open and re-arrange views (see section 3.1.6).

Note that if you move data between locations, the original data is kept. This means that you are essentially doing a copy instead of a move operation.

Copy using drag and drop

To copy instead of move using drag and drop, hold the Ctrl (⌘ on Mac) key while dragging:

click the element | click on the element again, and hold left mouse button | drag the element to the desired location | press Ctrl (⌘ on Mac) while you let go of mouse button release the Ctrl/⌘ button

4.1.6 Change element names

This section describes two ways of changing the names of sequences in the **Navigation Area**. In the first part, the sequences themselves are not changed - it's their representation that changes. The second part describes how to change the name of the element.

Change how sequences are displayed

Sequence elements can be displayed in the **Navigation Area** with different types of information:

- Name (this is the default information to be shown).
- Accession (sequences downloaded from databases like GenBank have an accession number).
- Latin name.
- Latin name (accession).

- Common name.
- Common name (accession).

Whether sequences can be displayed with this information depends on their origin. Sequences that you have created yourself or imported might not include this information, and you will only be able to see them represented by their name. However, sequences downloaded from databases like GenBank will include this information. To change how sequences are displayed:

**right-click any element or folder in the Navigation Area | Sequence Representation
| select format**

This will only affect sequence elements, and the display of other types of elements, e.g. alignments, trees and external files, will be not be changed. If a sequence does not have this information, there will be no text next to the sequence icon.

Rename element

Renaming a folder or an element in the **Navigation Area** can be done in three different ways:

select the element | Edit in the Menu Bar | Rename

or **select the element | F2**

click the element once | wait one second | click the element again

When you can rename the element, you can see that the text is selected and you can move the cursor back and forth in the text. When the editing of the name has finished; press **Enter** or select another element in the **Navigation Area**. If you want to discard the changes instead, press the **Esc**-key.

For renaming annotations instead of folders or elements, see section [11.3.3](#).

4.1.7 Delete elements

Deleting a folder or an element can be done in two ways:

right-click the element | Delete (🗑️)

or **select the element | press Delete key**

This will cause the element to be moved to the **Recycle Bin** (🗑️) where it is kept until the recycle bin is emptied. This means that you can recover deleted elements later on.

For deleting annotations instead of folders or elements, see section [11.3.4](#).

Restore Deleted Elements

The elements in the **Recycle Bin** (🗑️) can be restored by dragging the elements with the mouse into the folder where they used to be.

If you have deleted large amounts of data taking up very much disk space, you can free this disk space by emptying the **Recycle Bin** (🗑️):

Edit in the Menu Bar | Empty Recycle Bin (🗑️)

Note! This cannot be undone, and you will therefore not be able to recover the data present in the recycle bin when it was emptied.

4.1.8 Show folder elements in a table

A location or a folder might contain large amounts of elements. It is possible to view their elements in the **View Area**:

select a folder or location | **Show** () in the **Toolbar**

or

select a folder or location | right click on the folder and select **Show** () | **Contents** ()

An example is shown in figure 4.5.

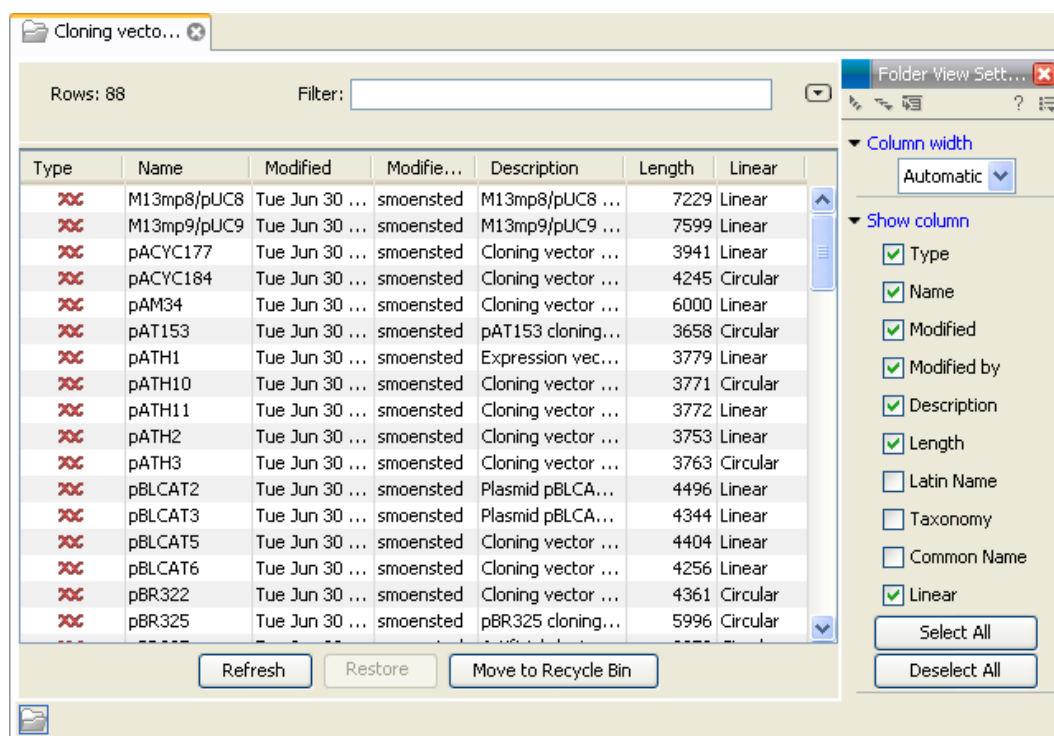

Figure 4.5: Viewing the elements in a folder.

When the elements are shown in the view, they can be sorted by clicking the heading of each of the columns. You can further refine the sorting by pressing Ctrl (⌘ on Mac) while clicking the heading of another column.

Sorting the elements in a view does not affect the ordering of the elements in the **Navigation Area**.

Note! The view only displays one "layer" at a time: the content of subfolders is not visible in this view. Also note that only sequences have the full span of information like organism etc.

Batch edit folder elements

You can select a number of elements in the table, right-click and choose **Edit** to batch edit the elements. In this way, you can change for example the description or common name of several elements in one go.

In figure 4.6 you can see an example where the common name of five sequence are renamed in one go. In this example, a dialog with a text field will be shown, letting you enter a new common name for these five sequences. **Note!** This information is directly saved and you cannot undo.

Type	Name	Modified	Modifi...	Descri...	Length	Common Name	...
XX	M13mp8...	Tue Jun ...	smoensted	M13mp8...	7229		Li...
XX	M13mp9...	Tue Jun ...	smoensted	M13mp9...	7599		Li...
XX	pACYC177	Tue Jun ...	smoensted	Cloning ...	3941		Li...
XX	pACYC184	Tue Jun ...	smoensted	Cloning ...	4245		Li...
XX	pAM34	Tue Jun ...	smoensted	Cloning ...	6000		Li...
XX	pAT153	Tue Jun ...	smoensted	Cloning ...	3658		Li...
XX	pATH1	Tue Jun ...	smoensted	Cloning ...	3779		Li...
XX	pATH10	Tue Jun ...	smoensted	Cloning ...			Li...
XX	pATH11	Tue Jun ...	smoensted	Cloning ...			Li...
XX	pATH2	Tue Jun ...	smoensted	Cloning ...			Li...
XX	pATH3	Tue Jun ...	smoensted	Cloning ...			Li...
XX	pBLCAT2	Tue Jun ...	smoensted	Plasmid ...			Li...
XX	pBLCAT3	Tue Jun ...	smoensted	Plasmid ...			Li...
XX	pBLCAT5	Tue Jun ...	smoensted	Cloning ...			Li...

Figure 4.6: Changing the common name of five sequences.

4.2 Customized attributes on data locations

The *CLC Main Workbench* makes it possible to define location-specific attributes on all elements stored in a data location. This could be company-specific information such as LIMS id, freezer position etc. Note that the attributes scheme belongs to a location, so if you have added multiple locations, they will have their own separate set of attributes.

4.2.1 Configuring which fields should be available

To configure which fields that should be available¹:

right-click the data location | Location | Attribute Manager

This will display the dialog shown in figure 4.7.

Click the **Add Attribute** (+) button to create a new attribute. This will display the dialog shown in figure 4.8.

First, select what kind of attribute you wish to create. This affects the type of information that can be entered by the end users, and it also affects the way the data can be searched. The

¹If the data location is a server location, you need to be a server administrator to do this

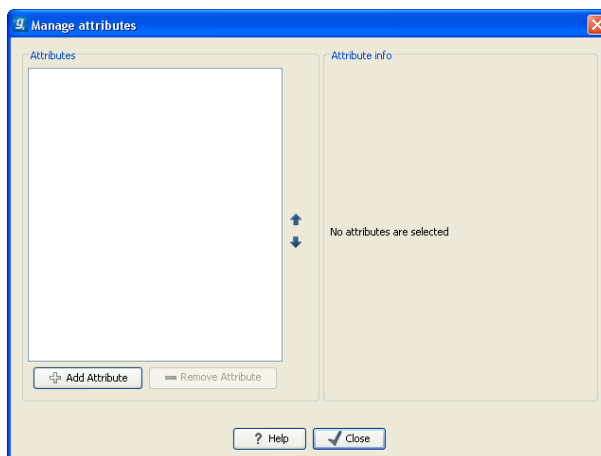

Figure 4.7: Adding attributes.

Figure 4.8: The list of attribute types.

following types are available:

- **Checkbox.** This is used for attributes that are binary (e.g. true/false, checked/unchecked and yes/no).
- **Text.** For simple text with no constraints on what can be entered.
- **List.** Lets you define a list of items that can be selected (explained in further detail below).
- **Number.** Any positive or negative integer.
- **Bounded number.** Same as number, but you can define the minimum and maximum values that should be accepted. If you designate some kind of ID to your sequences, you can use the bounded number to define that it should be at least 1 and max 99999 if that is the range of your IDs.
- **Decimal number.** Same as number, but it will also accept decimal numbers.
- **Bounded decimal number.** Same as bounded number, but it will also accept decimal numbers.
- **Hyper Link.** This can be used if the attribute is a reference to a web page. A value of this type will appear to the end user as a hyper link that can be clicked. Note that this

attribute can only contain one hyper link. If you need more, you will have to create additional attributes.

When you click **OK**, the attribute will appear in the list to the left. Clicking the attribute will allow you to see information on its type in the panel to the right.

4.2.2 Editing lists

Lists are a little special, since you have to define the items in the list. When you click a list in the left side of the dialog, you can define the items of the list in the panel to the right by clicking **Add Item (+)** (see figure 4.9).

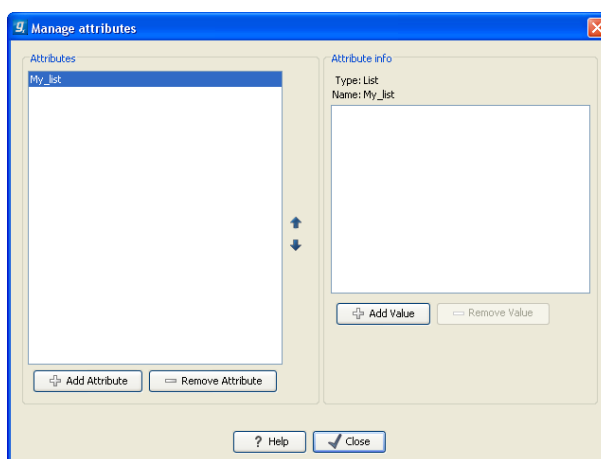

Figure 4.9: Defining items in a list.

Remove items in the list by pressing **Remove Item (-)**.

4.2.3 Removing attributes

To remove an attribute, select the attribute in the list and click **Remove Attribute (-)**. This can be done without any further implications if the attribute has just been created, but if you remove an attribute where values have already been given for elements in the data location, it will have implications for these elements: The values will not be removed, but they will become static, which means that they cannot be edited anymore. They can only be removed (see more about how this looks in the user interface below).

If you accidentally removed an attribute and wish to restore it, this can be done by creating a new attribute of exactly the same name and type as the one you removed. All the "static" values will now become editable again.

When you remove an attribute, it will no longer be possible to search for it, even if there is "static" information on elements in the data location.

Renaming and changing the type of an attribute is not possible - you will have to create a new one.

4.2.4 Changing the order of the attributes

You can change the order of the attributes by selecting an attribute and click the **Up** and **Down** arrows in the dialog. This will affect the way the attributes are presented for the user as described below.

4.3 Filling in values

When a set of attributes has been created (as shown in figure 4.10), the end users can start filling in information.

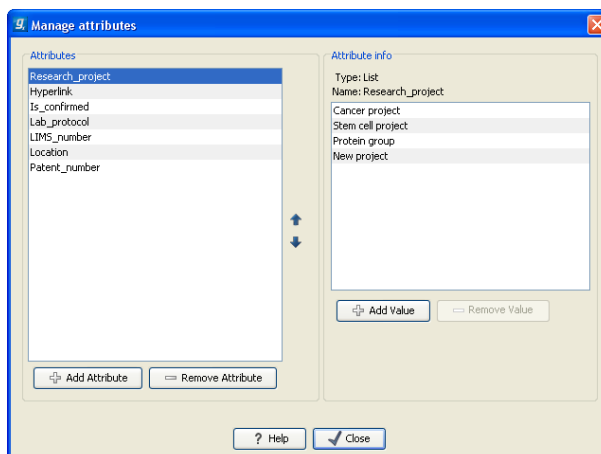

Figure 4.10: A set of attributes defined in the attribute manager.

This is done in the element info view:

right-click a sequence or another element in the Navigation Area | Show (📄) | Element info (📄)

This will open a view similar to the one shown in figure 4.11.

You can now enter the appropriate information and **Save**. When you have saved the information, you will be able to search for it (see below). Note that the sequence needs to be saved in the data location before you can edit the attribute values.

When nobody has entered information, the attribute will have a "Not set" written in red next to the attribute (see figure 4.12).

This is particularly useful for attribute types like checkboxes and lists where you cannot tell, from the displayed value, if it has been set or not. Note that when an attribute has not been set, you cannot search for it, even if it looks like it has a value. In figure 4.12, you will *not* be able to find this sequence if you search for research projects with the value "Cancer project", because it has not been set. To set it, simply click in the list and you will see the red "Not set" disappear.

If you wish to reset the information that has been entered for an attribute, press "Clear" (written in blue next to the attribute). This will return it to the "Not set" state.

The **Folder editor** provides a quick way of changing the attributes of many elements in one go (see section 4.1.8).

Figure 4.11: Adding values to the attributes.

Database Fields

- ▼ **Research project** Clear
Cancer project Not set

Figure 4.12: An attribute which has not been set.

4.3.1 What happens when the sequence is copied to another data location?

The user supplied information, which has been entered in the **Element info**, is attached to the attributes that have been defined in this particular data location. If you copy the sequence to another data location or to a data location containing another attribute set, the information will become fixed, meaning that it is no longer editable and cannot be searched for. Note that attributes that were "Not set" will disappear when you copy data to another location.

If the sequence is moved back to the original data location, the information will again be editable and searchable.

4.3.2 Searching

When an attribute has been created, it will automatically be available for searching. This means that in the **Local Search** () you can select the attribute in the list of search criteria (see figure 4.13).

It will also be available in the **Quick Search** below the **Navigation Area** (press Shift+F1 and it will be listed - see figure 4.14).

Figure 4.13: The attributes from figure 4.10 are now listed in the search filter.

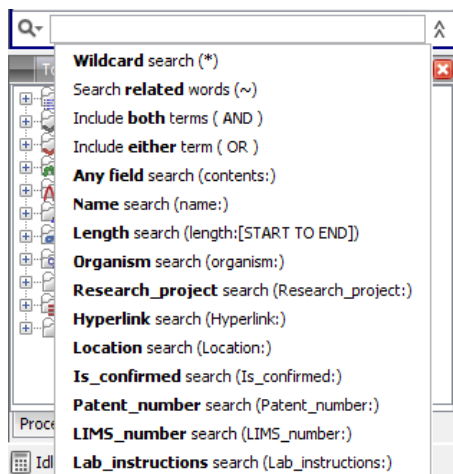

Figure 4.14: The attributes from figure 4.10 are now available in the Quick Search as well.

4.4 Local search

There are two ways of doing text-based searches of your data, as described in this section:

- **Quick-search** directly from the search field in the **Navigation Area**.
- **Advanced search** which makes it easy to make more specific searches.

In most cases, quick-search will find what you need, but if you need to be more specific in your search criteria, the advanced search is preferable.

4.4.1 What kind of information can be searched?

Below is a list of the different kinds of information that you can search for (applies to both quick-search and the advanced search).

- **Name.** The name of a sequence, an alignment or any other kind of element. The name is what is displayed in the **Navigation Area** per default.
- **Length.** The length of the sequence.
- **Organism.** Sequences which contain information about organism can be searched. In this way, you could search for e.g. *Homo sapiens* sequences.
- **Custom attributes.** Read more in section 4.2

Only the first item in the list, **Name**, is available for all kinds of data. The rest is only relevant for sequences.

If you wish to perform a search for sequence similarity, use Local BLAST (see section 13.1.3) instead.

4.4.2 Quick search

At the bottom of the **Navigation Area** there is a text field as shown in figure 4.15).

Figure 4.15: Search simply by typing in the text field and press Enter.

To search, simply enter a text to search for and press **Enter**.

Quick search results

To show the results, the search pane is expanded as shown in figure 4.16).

Figure 4.16: Search results.

If there are many hits, only the 50 first hits are immediately shown. At the bottom of the pane you can click **Next** (→) to see the next 50 hits (see figure 4.17).

If a search gives no hits, you will be asked if you wish to search for matches that start with your search term. If you accept this, an asterisk (*) will be appended to the search term.

Pressing the Alt key while you click a search result will high-light the search hit in its folder in the **Navigation Area**.

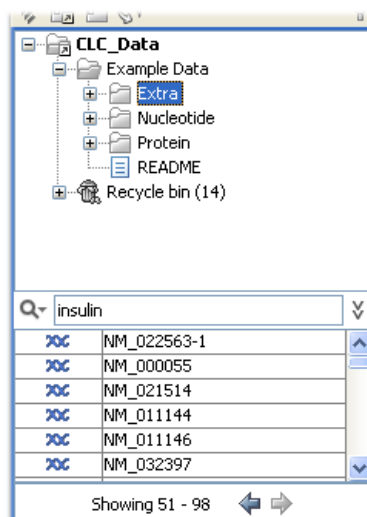

Figure 4.17: Page two of the search results.

In the preferences (see Chapter 5), you can specify the number of hits to be shown.

Special search expressions

When you write a search term in the search field, you can get help to write a more advanced search expression by pressing **Shift+F1**. This will reveal a list of guides as shown in figure 4.18.

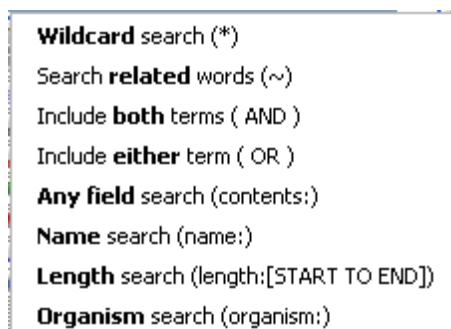

Figure 4.18: Guides to help create advanced search expressions.

You can select any of the guides (using mouse or keyboard arrows), and start typing. If you e.g. wish to search for sequences named BRCA1, select "Name search (name:)", and type "BRCA1". Your search expression will now look like this: "name:BRCA1".

The guides available are these:

- **Wildcard search (*)**. Appending an asterisk * to the search term will find matches starting with the term. E.g. searching for "brca*" will find both *brca1* and *brca2*.
- **Search related words ()**. If you don't know the exact spelling of a word, you can append a question mark to the search term. E.g. "brac1*" will find sequences with a *brca1* gene.
- **Include both terms (AND)**. If you write two search terms, you can define if your results have to match both search terms by combining them with AND. E.g. search for "brca1 AND human" will find sequences where *both* terms are present.

- **Include either term (OR).** If you write two search terms, you can define that your results have to match either of the search terms by combining them with OR. E.g. search for "brca1 OR brca2" will find sequences where *either* of the terms is present.
- **Name search (name:).** Search only the name of element.
- **Organism search (organism:).** For sequences, you can specify the organism to search for. This will look in the "Latin name" field which is seen in the **Sequence Info** view (see section 11.4).
- **Length search (length:[START TO END]).** Search for sequences of a specific length. E.g. search for sequences between 1000 and 2000 residues: "length:1000 TO 2000".

Note! If you have added attributes (see section 4.2), these will also appear on the list when pressing **Shift+F1**.

If you do not use this special syntax, you will automatically search for both name, description, organism, etc., and search terms will be combined as if you had put OR between them.

Search for data locations

The search function can also be used to search for a specific URL. This can be useful if you work on a server and wish to share a data location with another user. A simple example is shown in figure 4.19. Right click on the object name in the Navigation area (in this case ATP8a1 genomic sequence) and select "Copy". When you use the paste function in a destination outside the Workbench (e.g. in a text editor or in an email), the data location will become visible. The URL can now be used in the search field in the Workbench to locate the object.

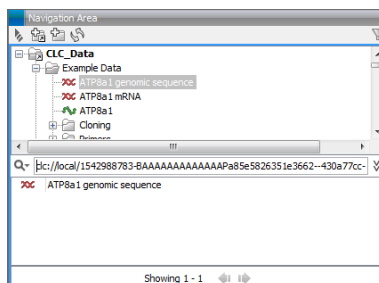

Figure 4.19: The search field can also be used to search for data locations.

Quick search history

You can access the 10 most recent searches by clicking the icon (Q-) next to the search field (see figure 4.20).

Clicking one of the recent searches will conduct the search again.

4.4.3 Advanced search

As a supplement to the **Quick search** described in the previous section you can use the more advanced search:

Edit | Local Search (🔍)

Figure 4.20: Recent searches.

or **Ctrl + F** (**⌘ + F** on Mac)

This will open the search view as shown in figure 4.21

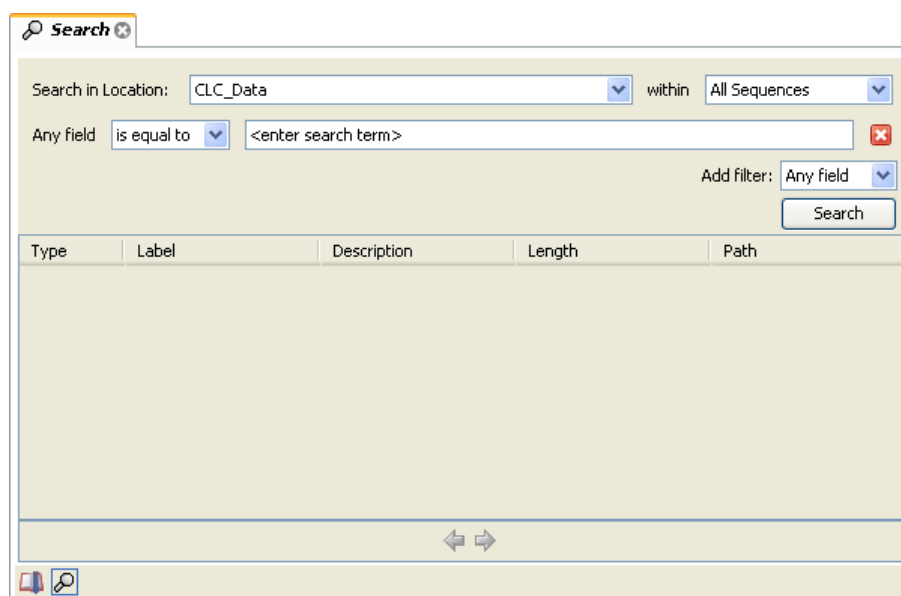

Figure 4.21: Advanced search.

The first thing you can choose is which location should be searched. All the active locations are shown in this list. You can also choose to search all locations. Read more about locations in section 4.1.1.

Furthermore, you can specify what kind of elements should be searched:

- All sequences
- Nucleotide sequences
- Protein sequences
- All data

When searching for sequences, you will also get alignments, sequence lists etc as result, if they contain a sequence which match the search criteria.

Below are the search criteria. First, select a relevant search filter in the **Add filter:** list. For sequences you can search for

- Name
- Length
- Organism

See section 4.4.2 for more information on individual search terms.

For all other data, you can only search for name.

If you use **Any field**, it will search all of the above plus the following:

- Description
- Keywords
- Common name
- Taxonomy name

To see this information for a sequence, switch to the **Element Info**  view (see section 11.4).

For each search line, you can choose if you want the exact term by selecting "is equal to" or if you only enter the start of the term you wish to find (select "begins with").

An example is shown in figure 4.22.

The screenshot shows a search interface with the following details:

- Search in Location:** CLC_Data
- within:** Nucleotide Sequence
- Organism:** is equal to homo sapiens
- Length:** is less than 10000
- Add filter:** Length
- Search** button

Type	Label	Description	Length	Path
	BC030969	Homo sapiens breast cancer 1, early onset, mRNA (c...	2090	{CLC_Data}
	BC072418	Homo sapiens breast cancer 1, early onset, mRNA (c...	3273	{CLC_Data}
	BC106745	Homo sapiens breast cancer 1, early onset, mRNA (c...	1468	{CLC_Data}
	BC106746	Homo sapiens breast cancer 1, early onset, mRNA (c...	779	{CLC_Data}
	BC115037	Homo sapiens breast cancer 1, early onset, mRNA (c...	5854	{CLC_Data}
	BC062429	Homo sapiens breast cancer 1, early onset, mRNA (c...	1322	{CLC_Data}

Showing 1 - 6 

Figure 4.22: Searching for human sequences shorter than 10,000 nucleotides.

This example will find human nucleotide sequences (organism is *Homo sapiens*), and it will only find sequences shorter than 10,000 nucleotides.

Note that a search can be saved  for later use. You do not save the search results - only the search parameters. This means that you can easily conduct the same search later on when your data has changed.

4.4.4 Search index

This section has a technical focus and is not relevant if your search works fine.

However, if you experience problems with your search results: if you do not get the hits you expect, it might be because of an index error.

The *CLC Main Workbench* automatically maintains an index of all data in all locations in the **Navigation Area**. If this index becomes out of sync with the data, you will experience problems with strange results. In this case, you can rebuild the index:

Right-click the relevant location | Location | Rebuild Index

This will take a while depending on the size of your data. At any time, the process can be stopped in the process area, see section [3.3.1](#).

Chapter 5

User preferences and settings

Contents

5.1	General preferences	149
5.2	Default view preferences	151
5.2.1	Number formatting in tables	152
5.2.2	Import and export Side Panel settings	152
5.3	Data preferences	153
5.4	Advanced preferences	154
5.4.1	Default data location	154
5.4.2	NCBI BLAST	154
5.5	Export/import of preferences	154
5.5.1	The different options for export and importing	154
5.6	View settings for the Side Panel	155
5.6.1	Floating Side Panel	157

The first three sections in this chapter deal with the general preferences that can be set for *CLC Main Workbench* using the **Preferences** dialog. The next section explains how the settings in the **Side Panel** can be saved and applied to other views. Finally, you can learn how to import and export the preferences.

The **Preferences** dialog offers opportunities for changing the default settings for different features of the program.

The **Preferences** dialog is opened in one of the following ways and can be seen in figure 5.1:

Edit | Preferences ()

or **Ctrl + K** ( + ; on Mac)

5.1 General preferences

The **General** preferences include:

Figure 5.1: Preferences include General preferences, View preferences, Data preferences, and Advanced settings.

- **Undo Limit.** As default the undo limit is set to 500. By writing a higher number in this field, more actions can be undone. Undo applies to all changes made on sequences, alignments or trees. See section 3.1.5 for more on this topic.
- **Audit Support.** If this option is checked, all manual editing of sequences will be marked with an annotation on the sequence (see figure 5.2). Placing the mouse on the annotation will reveal additional details about the change made to the sequence (see figure 5.3). Note that no matter whether **Audit Support** is checked or not, all changes are also recorded in the **History** (📖) (see section 8).
- **Number of hits.** The number of hits shown in *CLC Main Workbench*, when e.g. searching NCBI. (The sequences shown in the program are not downloaded, until they are opened or dragged/saved into the Navigation Area.
- **Locale Setting.** Specify which country you are located in. This determines how punctuation is used in numbers all over the program.
- **Show Dialogs.** A lot of information dialogs have a checkbox: "Never show this dialog again". When you see a dialog and check this box in the dialog, the dialog will not be shown again. If you regret and wish to have the dialog displayed again, click the button in the General Preferences: **Show Dialogs**. Then all the dialogs will be shown again.

Figure 5.3: Details of the editing.

5.2 Default view preferences

There are five groups of default **View** settings:

1. **Toolbar**
2. **Side Panel Location**
3. **New View**
4. **View Format**
5. **User Defined View Settings.**

In general, these are default settings for the user interface.

The **Toolbar preferences** let you choose the size of the toolbar icons, and you can choose whether to display names below the icons.

The **Side Panel Location** setting lets you choose between **Dock in views** and **Float in window**. When docked in view, view preferences will be located in the right side of the view of e.g. an alignment. When floating in window, the side panel can be placed everywhere in your screen, also outside the workspace, e.g. on a different screen. See section 5.6 for more about floating side panels.

The **New view** setting allows you to choose whether the **View preferences** are to be shown automatically when opening a new view. If this option is not chosen, you can press (Ctrl + U (⌘ + U on Mac)) to see the preferences panels of an open view.

The **View Format** allows you to change the way the elements appear in the **Navigation Area**. The following text can be used to describe the element:

- Name (this is the default information to be shown).
- Accession (sequences downloaded from databases like GenBank have an accession number).
- Latin name.
- Latin name (accession).
- Common name.
- Common name (accession).

The **User Defined View Settings** gives you an overview of the different **Side Panel** settings that are saved for each view. See section 5.6 for more about how to create and save style sheets.

If there are other settings beside **CLC Standard Settings**, you can use this overview to choose which of the settings should be used per default when you open a view (see an example in figure 5.4).

In this example, the **CLC Standard Settings** is chosen as default.

Figure 5.4: Selecting the default view setting.

5.2.1 Number formatting in tables

In the preferences, you can specify how the numbers should be formatted in tables (see figure 5.5).

Figure 5.5: Number formatting of tables.

The examples below the text field are updated when you change the value so that you can see the effect. After you have changed the preference, you have to re-open your tables to see the effect.

5.2.2 Import and export Side Panel settings

If you have created a special set of settings in the **Side Panel** that you wish to share with other CLC users, you can export the settings in a file. The other user can then import the settings.

To export the **Side Panel** settings, first select the views that you wish to export settings for. Use Ctrl+click (⌘ + click on Mac) or Shift+click to select multiple views. Next click the **Export...** button. Note that there is also another export button at the very bottom of the dialog, but this will export the other settings of the **Preferences** dialog (see section 5.5).

A dialog will be shown (see figure 5.6) that allows you to select which of the settings you wish to export.

When multiple views are selected for export, all the view settings for the views will be shown in the dialog. Click **Export** and you will now be able to define a save folder and name for the exported file. The settings are saved in a file with a .vsf extension (View Settings File).

To import a **Side Panel** settings file, make sure you are at the bottom of the **View** panel of the

Figure 5.6: Exporting all settings for circular views.

Preferences dialog, and click the **Import...** button. Note that there is also another import button at the very bottom of the dialog, but this will import the other settings of the **Preferences** dialog (see section 5.5).

The dialog asks if you wish to overwrite existing **Side Panel** settings, or if you wish to merge the imported settings into the existing ones (see figure 5.7).

Figure 5.7: When you import settings, you are asked if you wish to overwrite existing settings or if you wish to merge the new settings into the old ones.

Note! If you choose to overwrite the existing settings, you will lose all the **Side Panel** settings that you have previously saved.

To avoid confusion of the different import and export options, here is an overview:

- Import and export of **bioinformatics data** such as sequences, alignments etc. (described in section 7.1).
- **Graphics** export of the views which creates image files in various formats (described in section 7.3).
- Import and export of **Side Panel Settings** as described above.
- Import and export of all the **Preferences** except the Side Panel settings. This is described in the previous section.

5.3 Data preferences

The data preferences contain preferences related to interpretation of data, e.g. linker sequences:

- Predefined primer additions for Gateway cloning (see section 21.2.1).

5.4 Advanced preferences

The **Advanced** settings include the possibility to set up a proxy server. This is described in section 1.8.

5.4.1 Default data location

If you have more than one location in the **Navigation Area**, you can choose which location should be the default data location. The default location is used when you e.g. import a file without selecting a folder or element in the **Navigation Area** first. Then the imported element will be placed in the default location.

Note! The default location cannot be removed. You have to select another location as default first.

5.4.2 NCBI BLAST

URL to use for BLAST

It is possible to specify an alternate server URL to use for BLAST searches. The standard URL for the BLAST server at NCBI is: <http://blast.ncbi.nlm.nih.gov/Blast.cgi>.

Note! Be careful to specify a valid URL, otherwise BLAST will not work.

5.5 Export/import of preferences

The user preferences of the *CLC Main Workbench* can be exported to other users of the program, allowing other users to display data with the same preferences as yours. You can also use the export/import preferences function to backup your preferences.

To export preferences, open the **Preferences** dialog (Ctrl + K (⌘ + ; on Mac)) and do the following:

Export | Select the relevant preferences | Export | Choose location for the exported file | Enter name of file | Save

Note! The format of exported preferences is .cpf. This notation must be submitted to the name of the exported file in order for the exported file to work.

Before exporting, you are asked about which of the different settings you want to include in the exported file. One of the items in the list is "User Defined View Settings". If you export this, only the information about which of the settings is the default setting for each view is exported. If you wish to export the **Side Panel Settings** themselves, see section 5.2.2.

The process of importing preferences is similar to exporting:

Press Ctrl + K (⌘ + ; on Mac) to open Preferences | Import | Browse to and select the .cpf file | Import and apply preferences

5.5.1 The different options for export and importing

To avoid confusion of the different import and export options, here is an overview:

- Import and export of **bioinformatics data** such as sequences, alignments etc. (described in section 7.1).
- **Graphics** export of the views which creates image files in various formats (described in section 7.3).
- Import and export of **Side Panel Settings** as described in the next section.
- Import and export of all the **Preferences** except the Side Panel settings. This is described above.

5.6 View settings for the Side Panel

The **Side Panel** is shown to the right of all views that are opened in *CLC Main Workbench*. By using the settings in the **Side Panel** you can specify how the layout and contents of the view. Figure 5.8 is an example of the **Side Panel** of a sequence view.

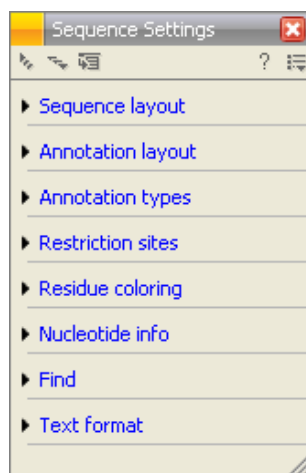

Figure 5.8: The Side Panel of a sequence contains several groups: Sequence layout, Annotation types, Annotation layout, etc. Several of these groups are present in more views. E.g. Sequence layout is also in the Side Panel of alignment views.

By clicking the black triangles or the corresponding headings, the groups can be expanded or collapsed. An example is shown in figure 5.9 where the **Sequence layout** is expanded.

The content of the groups is described in the sections where the functionality is explained. E.g. **Sequence Layout** for sequences is described in chapter 11.1.1.

When you have adjusted a view of e.g. a sequence, your settings in the **Side Panel** can be saved. When you open other sequences, which you want to display in a similar way, the saved settings can be applied. The options for saving and applying are available in the top of the **Side Panel** (see figure 5.10).

To save and apply the saved settings, click (☰) seen in figure 5.10. This opens a menu, where the following options are available:

- **Save Settings.** This brings up a dialog as shown in figure 5.11 where you can enter a name for your settings. Furthermore, by clicking the checkbox **Always apply these settings**, you can choose to use these settings every time you open a new view of this type. If you wish

Figure 5.9: The Sequence layout is expanded.

Figure 5.10: At the top of the Side Panel you can: Expand all groups, Collapse all preferences, Dock/Undock preferences, Help, and Save/Restore preferences.

to change which settings should be used per default, open the **Preferences** dialog (see section 5.2).

- **Delete Settings.** Opens a dialog to select which of the saved settings to delete.
- **Apply Saved Settings.** This is a submenu containing the settings that you have previously saved. By clicking one of the settings, they will be applied to the current view. You will also see a number of pre-defined view settings in this submenu. They are meant to be examples of how to use the **Side Panel** and provide quick ways of adjusting the view to common usages. At the bottom of the list of settings you will see **CLC Standard Settings** which represent the way the program was set up, when you first launched it.

Figure 5.11: The save settings dialog.

The settings are specific to the type of view. Hence, when you save settings of a circular view, they will not be available if you open the sequence in a linear view.

Figure 5.12: Applying saved settings.

If you wish to export the settings that you have saved, this can be done in the **Preferences** dialog under the **View** tab (see section 5.2.2).

The remaining icons of figure 5.10 are used to; **Expand all groups**, **Collapse all groups**, and **Dock/Undock Side Panel**. **Dock/Undock Side Panel** is to make the **Side Panel** "floating" (see below).

5.6.1 Floating Side Panel

The Side Panel of the views can be placed in the right side of a view, or it can be floating (see figure 5.13).

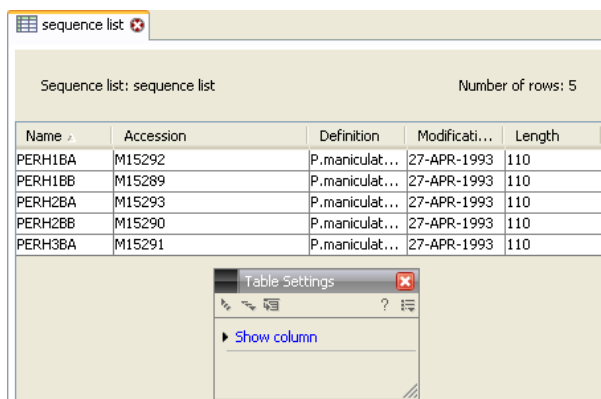

Figure 5.13: The floating Side Panel can be moved out of the way, e.g. to allow for a wider view of a table.

By clicking the Dock icon (☰) the floating Side Panel reappear in the right side of the view. The size of the floating Side Panel can be adjusted by dragging the hatched area in the bottom right.

Chapter 6

Printing

Contents

6.1	Selecting which part of the view to print	159
6.2	Page setup	160
6.2.1	Header and footer	161
6.3	Print preview	161

CLC Main Workbench offers different choices of printing the result of your work.

This chapter deals with printing directly from *CLC Main Workbench*. Another option for using the graphical output of your work, is to export graphics (see chapter 7.3) in a graphic format, and then import it into a document or a presentation.

All the kinds of data that you can view in the **View Area** can be printed. The *CLC Main Workbench* uses a WYSIWYG principle: What You See Is What You Get. This means that you should use the options in the Side Panel to change how your data, e.g. a sequence, looks on the screen. When you print it, it will look exactly the same way on print as on the screen.

For some of the views, the layout will be slightly changed in order to be printer-friendly.

It is not possible to print elements directly from the **Navigation Area**. They must first be opened in a view in order to be printed. To print the contents of a view:

select relevant view | Print () in the toolbar

This will show a print dialog (see figure 6.1).

In this dialog, you can:

- Select which part of the view you want to print.
- Adjust **Page Setup**.
- See a print **Preview** window.

These three options are described in the three following sections.

Figure 6.1: The Print dialog.

6.1 Selecting which part of the view to print

In the print dialog you can choose to:

- **Print visible area**, or
- **Print whole view**

These options are available for all views that can be zoomed in and out. In figure 6.2 is a view of a circular sequence which is zoomed in so that you can only see a part of it.

Figure 6.2: A circular sequence as it looks on the screen.

When selecting **Print visible area**, your print will reflect the part of the sequence that is *visible* in the view. The result from printing the view from figure 6.2 and choosing **Print visible area** can be seen in figure 6.3.

Figure 6.3: A print of the sequence selecting Print visible area.

On the other hand, if you select **Print whole view**, you will get a result that looks like figure 6.4. This means that you also print the part of the sequence which is not visible when you have zoomed in.

Figure 6.4: A print of the sequence selecting *Print whole view*. The whole sequence is shown, even though the view is zoomed in on a part of the sequence.

6.2 Page setup

No matter whether you have chosen to print the visible area or the whole view, you can adjust page setup of the print. An example of this can be seen in figure 6.5

Figure 6.5: *Page Setup*.

In this dialog you can adjust both the setup of the pages and specify a header and a footer by clicking the tab at the top of the dialog.

You can modify the layout of the page using the following options:

- **Orientation.**
 - **Portrait.** Will print with the paper oriented vertically.
 - **Landscape.** Will print with the paper oriented horizontally.
- **Paper size.** Adjust the size to match the paper in your printer.
- **Fit to pages.** Can be used to control how the graphics should be split across pages (see figure 6.6 for an example).
 - **Horizontal pages.** If you set the value to e.g. 2, the printed content will be broken up horizontally and split across 2 pages. This is useful for sequences that are not wrapped
 - **Vertical pages.** If you set the value to e.g. 2, the printed content will be broken up vertically and split across 2 pages.

Note! It is a good idea to consider adjusting view settings (e.g. **Wrap** for sequences), in the **Side Panel** before printing. As explained in the beginning of this chapter, the printed material will look like the view on the screen, and therefore these settings should also be considered when adjusting **Page Setup**.

Figure 6.6: An example where *Fit to pages horizontally* is set to 2, and *Fit to pages vertically* is set to 3.

6.2.1 Header and footer

Click the **Header/Footer** tab to edit the header and footer text. By clicking in the text field for either **Custom header text** or **Custom footer text** you can access the auto formats for header/footer text in **Insert a caret position**. Click either **Date**, **View name**, or **User name** to include the auto format in the header/footer text.

Click **OK** when you have adjusted the **Page Setup**. The settings are saved so that you do not have to adjust them again next time you print. You can also change the **Page Setup** from the **File** menu.

6.3 Print preview

The preview is shown in figure 6.7.

Figure 6.7: *Print preview.*

The **Print preview** window lets you see the layout of the pages that are printed. Use the arrows in the toolbar to navigate between the pages. Click Print () to show the print dialog, which lets you choose e.g. which pages to print.

The **Print preview** window is for preview only - the layout of the pages must be adjusted in the **Page setup**.

Chapter 7

Import/export of data and graphics

7.4	Export graph data points to a file	173
7.5	Copy/paste view output	175

CLC Main Workbench handles a large number of different data formats. In order to work with data in the Workbench, it has to be imported (📁). Data types that are not recognized by the Workbench are imported as "external files" which means that when you open these, they will open in the default application for that file type on your computer (e.g. Word documents will open in Word).

This chapter first deals with importing and exporting data in bioinformatic data formats and as external files. Next comes an explanation of how to export graph data points to a file, and how export graphics.

7.1 Standard import

CLC Main Workbench has support for a wide range of bioinformatic data such as sequences, alignments etc. See a full list of the data formats in section [J.1](#).

These data can be imported through the Import dialog, using drag/drop or copy/paste as explained below.

7.1.1 Import using the import dialog

To start the import using the import dialog:

click **Import** () in the **Toolbar**

This will show a dialog similar to figure 7.1. You can change which kind of file types that should be shown by selecting a file format in the **Files of type** box.

Figure 7.1: The import dialog.

Next, select one or more files or folders to import and click **Next**.

This allows you to select a place for saving the result files.

If you import one or more folders, the contents of the folder is automatically imported and placed in that folder in the **Navigation Area**. If the folder contains subfolders, the whole folder structure is imported.

In the import dialog (figure 7.1), there are three import options:

Automatic import This will import the file and *CLC Main Workbench* will try to determine the format of the file. The format is determined based on the file extension (e.g. SwissProt files have .swp at the end of the file name) in combination with a detection of elements in the file that are specific to the individual file formats. If the file type is not recognized, it will be imported as an external file. In most cases, automatic import will yield a successful result, but if the import goes wrong, the next option can be helpful:

Force import as type This option should be used if *CLC Main Workbench* cannot successfully determine the file format. By forcing the import as a specific type, the automatic determination of the file format is bypassed, and the file is imported as the type specified.

Force import as external file This option should be used if a file is imported as a bioinformatics file when it should just have been external file. It could be an ordinary text file which is imported as a sequence.

7.1.2 Import using drag and drop

It is also possible to drag a file from e.g. the desktop into the **Navigation Area** of *CLC Main Workbench*. This is equivalent to importing the file using the **Automatic import** option described above. If the file type is not recognized, it will be imported as an external file.

7.1.3 Import using copy/paste of text

If you have e.g. a text file or a browser displaying a sequence in one of the formats that can be imported by *CLC Main Workbench*, there is a very easy way to get this sequence into the **Navigation Area**:

**Copy the text from the text file or browser | Select a folder in the Navigation Area
| Paste (📄)**

This will create a new sequence based on the text copied. This operation is equivalent to saving the text in a text file and importing it into the *CLC Main Workbench*.

If the sequence is not formatted, i.e. if you just have a text like this: "ATGACGAATAGGAGTTC-TAGCTA" you can also paste this into the **Navigation Area**.

Note! Make sure you copy all the relevant text - otherwise *CLC Main Workbench* might not be able to interpret the text.

7.1.4 External files

In order to help you organize your research projects, *CLC Main Workbench* lets you import all kinds of files. E.g. if you have Word, Excel or pdf-files related to your project, you can import them into the **Navigation Area** of *CLC Main Workbench*. Importing an external file creates a copy of the file which is stored at the location you have chosen for import. The file can now be opened by double-clicking the file in the **Navigation Area**. The file is opened using the default application for this file type (e.g. Microsoft Word for .doc-files and Adobe Reader for .pdf).

External files are imported and exported in the same way as bioinformatics files (see section 7.1). Bioinformatics files not recognized by *CLC Main Workbench* are also treated as external files.

7.1.5 Import Vector NTI data

There are several ways of importing your Vector NTI data into the CLC Workbench. The best way to go depends on how your data is currently stored in Vector NTI:

- Your data is stored in the Vector NTI Local Database which can be accessed through Vector NTI Explorer. This is described in the first section below.
- Your data is stored as single files on your computer (just like Word documents etc.). This is described in the second section below.

Import from the Vector NTI Local Database

If your Vector NTI data are stored in a Vector NTI Local Database (as the one shown in figure 7.2), you can import all the data in one step, or you can import selected parts of it.

Name	Length	Form	Storage ...	Author	Origin
ADCY7	6196	Linear	Basic	NCBI Entrez	NCBI
Adeno2	35937	Linear	Basic	NCBI Entrez	NCBI
ADRA1A	2306	Linear	Basic	NCBI Entrez	NCBI
BaculoDirect Linear DNA	139370	Linear	Basic	Invitrogen	Invitrogen
BaculoDirect Linear DNA Clonin...	5770	Linear	Construc...	Invitrogen	Invitrogen

GNAI1	3367	Linear	Basic	NCBI Entrez	NCBI

343 DNA/RNA molecules

Figure 7.2: Data stored in the Vector NTI Local Database accessed through Vector NTI Explorer.

Importing the entire database in one step

From the Workbench, there is a direct import of the whole database (see figure 7.3):

File | Import Vector NTI Database

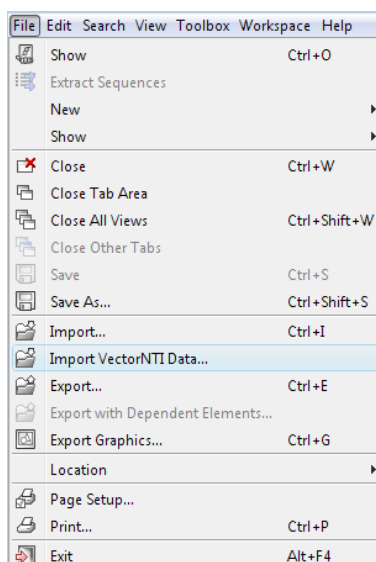

Figure 7.3: Import the whole Vector NTI Database.

This will bring up a dialog letting you choose to import from the default location of the database, or you can specify another location. If the database is installed in the default folder, like e.g. `C:\VNTI Database`, press **Yes**. If not, click **No** and specify the database folder manually.

When the import has finished, the data will be listed in the **Navigation Area** of the Workbench as shown in figure 7.4.

If something goes wrong during the import process, please report the problem to support@clcbio.com. To circumvent the problem, see the following section on how to import parts of the database. It will take a few more steps, but you will most likely be able to import this way.

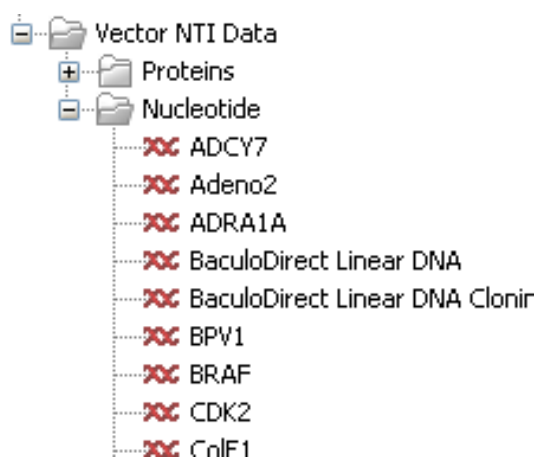

Figure 7.4: The Vector NTI Data folder containing all imported sequences of the Vector NTI Database.

Importing parts of the database

Instead of importing the whole database automatically, you can export parts of the database from Vector NTI Explorer and subsequently import into the Workbench. First, export a selection of files as an archive as shown in figure 7.5.

Figure 7.5: Select the relevant files and export them as an archive through the File menu.

This will produce a file with a ma4-, pa4- or oa4-extension. Back in the CLC Workbench, click **Import** (📁) and select the file.

Importing single files

In Vector NTI, you can save a sequence in a file instead of in the database (see figure 7.6).

This will give you file with a .gb extension. This file can be easily imported into the CLC Workbench:

Import (📁) | **select the file** | **Select**

You don't have to import one file at a time. You can simply select a bunch of files or an entire folder, and the CLC Workbench will take care of the rest. Even if the files are in different formats.

You can also simply drag and drop the files into the **Navigation Area** of the CLC Workbench.

Figure 7.6: Saving a sequence as a file in Vector NTI.

The Vector NTI import is a plug-in which is pre-installed in the Workbench. It can be uninstalled and updated using the plug-in manager (see section 1.7).

7.2 Data export

CLC Main Workbench can export bioinformatic data in most of the formats that can be imported. There are a few exceptions. See section 7.1.

To export a file:

Select the elements to export | Export () | choose where to export to | select 'File of type' | enter name of file | Save

When exporting to CSV and tab delimited files, decimal numbers are formatted according to the Locale setting of the Workbench (see section 5.1). If you open the CSV or tab delimited file with spreadsheet software like Excel, you should make sure that both the Workbench and the spreadsheet software are using the same Locale.

Note! The **Export** dialog decides which types of files you are allowed to export into, depending on what type of data you want to export. E.g. protein sequences can be exported into GenBank, Fasta, Swiss-Prot and CLC-formats.

Export of folders and multiple elements

The .zip file type can be used to export all kinds of files and is therefore especially useful in these situations:

- Export of one or more folders including all underlying elements and folders.
- If you want to export two or more elements into one file.

Export of folders is similar to export of single files. Exporting multiple files (of different formats) is done in .zip-format. This is how you export a folder:

select the folder to export | Export (📁) | choose where to export to | enter name | Save

You can export multiple files of the same type into formats other than ZIP (.zip). E.g. two DNA sequences can be exported in GenBank format:

select the two sequences by <Ctrl>-click (⌘-click on Mac) or <Shift>-click | Export (📁) | choose where to export to | choose GenBank (.gbk) format | enter name the new file | Save

Export of dependent elements

When exporting e.g. an alignment, *CLC Main Workbench* can export the alignment including all the sequences that were used to create it. This way, when sending your alignment (with the dependent sequences), your colleagues can reproduce your findings with adjusted parameters, if desired. To export with dependent files:

select the element in Navigation Area | File in Menu Bar | Export with Dependent Elements | enter name of of the new file | choose where to export to | Save

The result is a folder containing the exported file with dependent elements, stored automatically in a folder on the desired location of your desk.

Export history

To export an element's history:

select the element in Navigation Area Export (📁) | select History PDF(.pdf) | choose where to export to | Save

The entire history of the element is then exported in pdf format.

The CLC format

CLC Main Workbench keeps all bioinformatic data in the CLC format. Compared to other formats, the CLC format contains more information about the object, like its history and comments. The CLC format is also able to hold several elements of different types (e.g. an alignment, a graph and a phylogenetic tree). This means that if you are exporting your data to another CLC Workbench, you can use the CLC format to export several elements in one file, and you will preserve all the information.

Note! CLC files can be exported from and imported into all the different CLC Workbenches.

Backup

If you wish to secure your data from computer breakdowns, it is advisable to perform regular backups of your data. Backing up data in the *CLC Main Workbench* is done in two ways:

- Making a backup of each of the folders represented by the locations in the **Navigation Area**.
- Selecting all locations in the **Navigation Area** and do a zip export (📁). The resulting file will contain all the data stored in the **Navigation Area** and can be imported into *CLC Main*

Workbench if you wish to restore from the back-up at some point.

No matter which method is used for backup, you may have to re-define the locations in the **Navigation Area** if you restore your data from a computer breakdown.

7.3 Export graphics to files

CLC Main Workbench supports export of graphics into a number of formats. This way, the visible output of your work can easily be saved and used in presentations, reports etc. The **Export Graphics** function () is found in the **Toolbar**.

CLC Main Workbench uses a WYSIWYG principle for graphics export: What You See Is What You Get. This means that you should use the options in the Side Panel to change how your data, e.g. a sequence, looks in the program. When you export it, the graphics file will look exactly the same way.

It is not possible to export graphics of elements directly from the **Navigation Area**. They must first be opened in a view in order to be exported. To export graphics of the contents of a view:

select tab of View | Graphics () on Toolbar

This will display the dialog shown in figure 7.7.

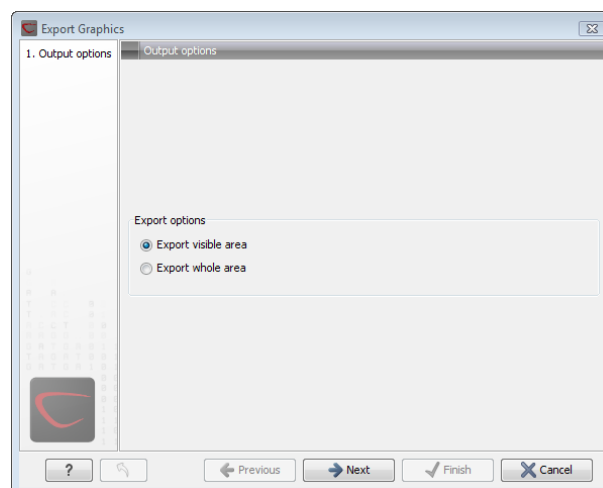

Figure 7.7: Selecting to export whole view or to export only the visible area.

7.3.1 Which part of the view to export

In this dialog you can choose to:

- **Export visible area**, or
- **Export whole view**

These options are available for all views that can be zoomed in and out. In figure 7.8 is a view of a circular sequence which is zoomed in so that you can only see a part of it.

Figure 7.8: A circular sequence as it looks on the screen.

When selecting **Export visible area**, the exported file will only contain the part of the sequence that is *visible* in the view. The result from exporting the view from figure 7.8 and choosing **Export visible area** can be seen in figure 7.9.

Figure 7.9: The exported graphics file when selecting *Export visible area*.

On the other hand, if you select **Export whole view**, you will get a result that looks like figure 7.10. This means that the graphics file will also include the part of the sequence which is not visible when you have zoomed in.

Figure 7.10: The exported graphics file when selecting *Export whole view*. The whole sequence is shown, even though the view is zoomed in on a part of the sequence.

For 3D structures, this first step is omitted and you will always export what is shown in the view (equivalent to selecting **Export visible area**).

Click **Next** when you have chosen which part of the view to export.

7.3.2 Save location and file formats

In this step, you can choose name and save location for the graphics file (see figure 7.11).

Figure 7.11: Location and name for the graphics file.

CLC Main Workbench supports the following file formats for graphics export:

Format	Suffix	Type
Portable Network Graphics	.png	bitmap
JPEG	.jpg	bitmap
Tagged Image File	.tif	bitmap
PostScript	.ps	vector graphics
Encapsulated PostScript	.eps	vector graphics
Portable Document Format	.pdf	vector graphics
Scalable Vector Graphics	.svg	vector graphics

These formats can be divided into bitmap and vector graphics. The difference between these two categories is described below:

Bitmap images

In a bitmap image, each dot in the image has a specified color. This implies, that if you zoom in on the image there will not be enough dots, and if you zoom out there will be too many. In these cases the image viewer has to interpolate the colors to fit what is actually looked at. A bitmap image needs to have a high resolution if you want to zoom in. This format is a good choice for storing images without large shapes (e.g. dot plots). It is also appropriate if you don't have the need for resizing and editing the image after export.

Vector graphics

Vector graphic is a collection of shapes. Thus what is stored is e.g. information about where a line starts and ends, and the color of the line and its width. This enables a given viewer to decide how to draw the line, no matter what the zoom factor is, thereby always giving a correct image. This format is good for e.g. graphs and reports, but less usable for e.g. dot plots. If the image is to be resized or edited, vector graphics are by far the best format to store graphics. If you open

a vector graphics file in an application like e.g. Adobe Illustrator, you will be able to manipulate the image in great detail.

Graphics files can also be imported into the **Navigation Area**. However, no kinds of graphics files can be displayed in *CLC Main Workbench*. See section 7.1.4 for more about importing external files into *CLC Main Workbench*.

7.3.3 Graphics export parameters

When you have specified the name and location to save the graphics file, you can either click **Next** or **Finish**. Clicking **Next** allows you to set further parameters for the graphics export, whereas clicking **Finish** will export using the parameters that you have set last time you made a graphics export in that file format (if it is the first time, it will use default parameters).

Parameters for bitmap formats

For bitmap files, clicking **Next** will display the dialog shown in figure 7.12.

Figure 7.12: Parameters for bitmap formats: size of the graphics file.

You can adjust the size (the resolution) of the file to four standard sizes:

- Screen resolution
- Low resolution
- Medium resolution
- High resolution

The actual size in pixels is displayed in parentheses. An estimate of the memory usage for exporting the file is also shown. If the image is to be used on computer screens only, a low resolution is sufficient. If the image is going to be used on printed material, a higher resolution is necessary to produce a good result.

Parameters for vector formats

For pdf format, clicking **Next** will display the dialog shown in figure 7.13 (this is only the case if the graphics is using more than one page).

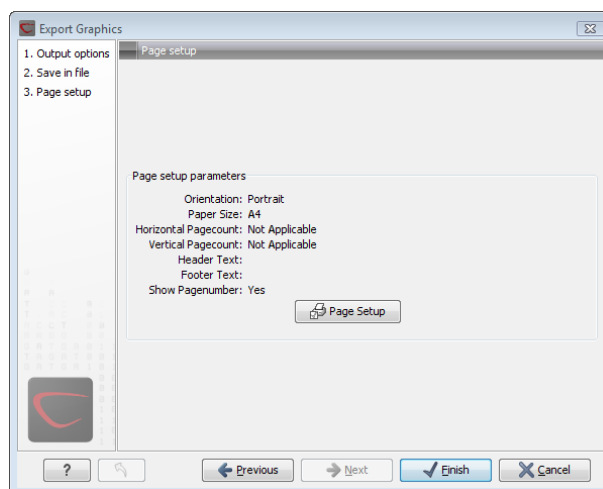

Figure 7.13: Page setup parameters for vector formats.

The settings for the page setup are shown, and clicking the **Page Setup** button will display a dialog where these settings can be adjusted. This dialog is described in section 6.2.

The page setup is only available if you have selected to export the whole view - if you have chosen to export the visible area only, the graphics file will be on one page with no headers or footers.

7.3.4 Exporting protein reports

It is possible to export a protein report using the normal **Export** function (📁) which will generate a pdf file with a table of contents:

Click the report in the Navigation Area | Export (📁) in the Toolbar | select pdf

You can also choose to export a protein report using the **Export graphics** function (🖨️), but in this way you will not get the table of contents.

7.4 Export graph data points to a file

Data points for graphs displayed along the sequence or along an alignment, mapping or BLAST result, can be exported to a semicolon-separated text file (csv format). An example of such a graph is shown in figure 7.14. This graph shows the coverage of reads of a read mapping (produced with *CLC Genomics Workbench*).

To export the data points for the graph, right-click the graph and choose **Export Graph to Comma-separated File**. Depending on what kind of graph you have selected, different options will be shown: If the graph is covering a set of aligned sequences with a main sequence, such as read mappings and BLAST results, the dialog shown in figure 7.15 will be displayed. These kinds of graphs are located under **Alignment info** in the Side Panel. In all other cases, a normal file dialog will be shown letting you specify name and location for the file.

In this dialog, select whether you wish to include positions where the main sequence (the

Figure 7.14: A graph displayed along the mapped reads. Right-click the graph to export the data points to a file.

Figure 7.15: Choosing to include data points with gaps

reference sequence for read mappings and the query sequence for BLAST results) has gaps. If you are exporting e.g. coverage information from a read mapping, you would probably want to exclude gaps, if you want the positions in the exported file to match the reference (i.e. chromosome) coordinates. If you export including gaps, the data points in the file no longer corresponds to the reference coordinates, because each gap will shift the coordinates.

Clicking **Next** will present a file dialog letting you specify name and location for the file.

The output format of the file is like this:

```
"Position";"Value";
"1";"13";
"2";"16";
"3";"23";
"4";"17";
```

...

7.5 Copy/paste view output

The content of tables, e.g. in reports, folder lists, and sequence lists can be copy/pasted into different programs, where it can be edited. *CLC Main Workbench* pastes the data in tabulator separated format which is useful if you use programs like Microsoft Word and Excel. There is a huge number of programs in which the copy/paste can be applied. For simplicity, we include one example of the copy/paste function from a **Folder Content** view to Microsoft Excel.

First step is to select the desired elements in the view:

click a line in the Folder Content view | hold Shift-button | press arrow down/up key

See figure 7.16.

Type	Name	Description	Length
X	AV738615	Homo sapiens hemoglobin delta-beta fusion protein (HBD/HBB) gene,...	180
X	HJMDINJC	Human dinucleotide repeat polymorphism at the D11S439 and HBB loci.	190
X	HJMH8B	Human beta globin region on chromosome 11.	73308
X	NM_000044	Homo sapiens androgen receptor (dihydrotestosterone receptor; testi...	4314
X	PERH2BD	P.maniculatus (deer mouse) beta-2-globin (Hbb-b2) DNA, 3' region.	194
X	PERH3BC	P.maniculatus (deer mouse) beta-3-globin (Hbb-b3) DNA, 3' region.	196
	sequence list		0

Figure 7.16: Selected elements in a Folder Content view.

When the elements are selected, do the following to copy the selected elements:

right-click one of the selected elements | Edit | Copy (📄)

Then:

right-click in the cell A1 | Paste (📄)

The outcome might appear unorganized, but with a few operations the structure of the view in *CLC Main Workbench* can be produced. (Except the icons which are replaced by file references in Excel.)

Note that all tables can also be **Exported** (📁) directly in Excel format.

Chapter 8

History log

Contents

8.1 Element history	176
8.1.1 Sharing data with history	177

CLC Main Workbench keeps a log of all operations you make in the program. If e.g. you rename a sequence, align sequences, create a phylogenetic tree or translate a sequence, you can always go back and check what you have done. In this way, you are able to document and reproduce previous operations.

This can be useful in several situations: It can be used for documentation purposes, where you can specify exactly how your data has been created and modified. It can also be useful if you return to a project after some time and want to refresh your memory on how the data was created. Also, if you have performed an analysis and you want to reproduce the analysis on another element, you can check the history of the analysis which will give you all parameters you set.

This chapter will describe how to use the **History** functionality of *CLC Main Workbench*.

8.1 Element history

You can view the history of all elements in the **Navigation Area** except files that are opened in other programs (e.g. Word and pdf-files). The history starts when the element appears for the first time in *CLC Main Workbench*. To view the history of an element:

Select the element in the Navigation Area | Show () in the Toolbar | History ()

or **If the element is already open | History () at the bottom left part of the view**

This opens a view that looks like the one in figure 8.1.

When opening an element's history is opened, the newest change is submitted in the top of the view. The following information is available:

- **Title.** The action that the user performed.
- **Date and time.** Date and time for the operation. The date and time are displayed according

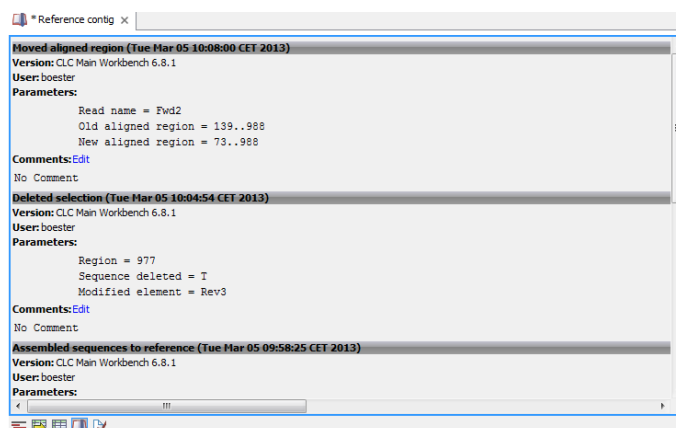

Figure 8.1: An element's history.

to your locale settings (see section 5.1).

- **User.** The user who performed the operation. If you import some data created by another person in a CLC Workbench, that person's name will be shown.
- **Parameters.** Details about the action performed. This could be the parameters that was chosen for an analysis.
- **Origins from.** This information is usually shown at the bottom of an element's history. Here, you can see which elements the current element originates from. If you have e.g. created an alignment of three sequences, the three sequences are shown here. Clicking the element selects it in the **Navigation Area**, and clicking the 'history' link opens the element's own history.
- **Comments.** By clicking **Edit** you can enter your own comments regarding this entry in the history. These comments are saved.

8.1.1 Sharing data with history

The history of an element is attached to that element, which means that exporting an element in CLC format (*.clc) will export the history too. In this way, you can share folders and files with others while preserving the history. If an element's history includes source elements (i.e. if there are elements listed in 'Origins from'), they must also be exported in order to see the full history. Otherwise, the history will have entries named "Element deleted". An easy way to export an element with all its source elements is to use the **Export Dependent Elements** function described in section 7.2.

The history view can be printed. To do so, click the **Print** icon (🖨️). The history can also be exported as a pdf file:

Select the element in the Navigation Area | Export (📄) | in "File of type" choose History PDF | Save

Chapter 9

Batching and result handling

Contents

9.1	Batch processing	178
9.1.1	Batch overview	179
9.1.2	Batch filtering and counting	180
9.1.3	Setting parameters for batch runs	180
9.1.4	Running the analysis and organizing the results	181
9.1.5	Running de novo assembly and read mapping in batch	181
9.2	How to handle results of analyses	182
9.2.1	Table outputs	183
9.2.2	Batch log	184

9.1 Batch processing

Most of the analyses in the **Toolbox** are able to perform the same analysis on several elements in one batch. This means that analyzing large amounts of data is very easily accomplished. As an example, if you use the **Find Binding Sites and Create Fragments (76)** tool, if you supply five sequences as shown in figure 9.1, the result table will present an overview of the results for all five sequences.

This is because the input sequences are pooled before running the analysis. If you want individual outputs for each sequence, you would need to run the tool five times, or alternatively use the **Batching mode**.

Batching mode is activated by clicking the **Batch** checkbox in dialog where the input data is selected. Batching simply means that each data set is run separately, just as if the tool has been run manually for each one. For some analyses, this simply means that each input sequence should be run separately, but in other cases it is desirable to pool sets of files together in one run. This selection of data for a batch run is defined as a **batch unit**.

When batching is selected, the data to be added is the folder containing the data you want to batch. The content of the folder is assigned into batch units based on this concept:

Figure 9.1: Inputting five sequences to Find Binding Sites and Create Fragments.

- All subfolders are treated as individual batch units. This means that if the subfolder contains several input files, they will be pooled as one batch unit. Nested subfolders (i.e. subfolders within the subfolder) are ignored.
- All files that are not in subfolders are treated as individual batch units.

An example of a batch run is shown in figure 9.2.

Figure 9.2: The Cloning folder includes both folders and sequences.

The `Cloning` folder that is found in the example data (see section 1.6.2) contains two sequences (✗) and three folders (📁). If you click **Batch**, only folders can be added to the list of selected elements in the right-hand side of the dialog. To run the contents of the `Cloning` folder in batch, double-click to select it.

When the `Cloning` folder is selected and you click **Next**, a batch overview is shown.

9.1.1 Batch overview

The batch overview lists the batch units to the left and the contents of the selected unit to the right (see figure 9.3).

Figure 9.3: Overview of the batch run.

In this example, the two sequences are defined as separate batch units because they are located at the top level of the Cloning folder. There were also three folders in the Cloning folder (see figure 9.2), and two of them are listed as well. This means that the contents of these folders are pooled in one batch run (you can see the contents of the `Cloning vector library` batch run in the panel at the right-hand side of the dialog). The reason why the `Enzyme lists` folder is not listed as a batch unit is that it does not contain any sequences.

In this overview dialog, the Workbench has filtered the data so that only the types of data accepted by the tool is shown (DNA sequences in the example above).

9.1.2 Batch filtering and counting

At the bottom of the dialog shown in figure 9.3, the Workbench counts the number of files that will be run in total (90 in this case). This is counted across all the batch units.

In some situations it is useful to filter the input for the batching based on names. As an example, this could be to include only paired reads for a mapping, by only allowing names where "paired" is part of the name.

This is achieved using the **Only use elements containing** and **Exclude elements containing** text fields. Note that the count is dynamically updated to reflect the number of input files based on the filtering.

If a complete batch unit should be removed, you can select it, right-click and choose **Remove Batch Unit**. You can also remove items from the contents of each batch unit using right-click and **Remove Element**.

9.1.3 Setting parameters for batch runs

For some tools, the subsequent dialogs depend on the input data. In this case, one of the units is specified as parameter prototype and will be used to guide the choices in the dialogs. Per default, this will be the first batch unit (marked in bold), but this can be changed by right-clicking another batch unit and click **Set as Parameter Prototype**.

Note that the Workbench is validating a lot of the input and parameters when running in normal

"non-batch" mode. When running in batch, this validation is not performed, and this means that some analyses will fail if combinations of input data and parameters are not right. Therefore batching should only be used when the batch units are very homogenous in terms of the type and size of data.

9.1.4 Running the analysis and organizing the results

At the last dialog before clicking **Finish**, it is only possible to use the **Save** option. When a tool is run in batch mode, the default behavior is to place the result files in the same folder as the input files. In the example shown in figure 9.3, the result of the two single sequences will be placed in the Cloning folder, whereas the results for the `Cloning vector library` and `Processed data` runs will be placed inside these folders.

However, there is an option to save the results in a separate folder structure by checking **Into separate folders**. This will allow you to specify a new save destination, and the *CLC Main Workbench* will create a subfolder for each batch unit where the results are saved..

When the batch run is started, there will be one "master" process representing the overall batch job, and there will then be a separate process for each batch unit. The behavior of this is different between Workbench and Server:

- When running the batch job in the Workbench, only one batch unit is run at a time. So when the first batch unit is done, the second will be started and so on. This is done in order to avoid many parallel analyses that would draw on the same compute resources and slow down the computer.
- When this is run on a CLC Server (see <http://clcbio.com/server>), all the processes are placed in the queue, and the queue is then taking care of distributing the jobs. This means that if the server set-up includes multiple nodes, the jobs can be run in parallel.

If you need to stop the whole batch run, you need to stop the "master" process.

9.1.5 Running de novo assembly and read mapping in batch

De novo assembly and read mapping are special in batch mode because they usually have the option of assigning individual mapping parameters to each input file. When running in batch mode this is not possible. Instead, you can change the default parameters used for long and short reads, respectively. You can also set the paired distance for paired data.

Note that this means that you cannot use a combination of paired-end and mate-pair data for batching.

Figure 9.4 shows the parameter dialog when running read mapping in batch.

Note that you can only specify one setting for all short reads, and one setting for all long reads. When the analysis is run, the reads are automatically categorized as either long or short, and the parameters specified in the dialog are applied. The same goes for all reads that are imported as paired where the minimum and maximum distances are applied.

Figure 9.4: Read mapping parameters in batch.

9.2 How to handle results of analyses

This section will explain how results generated from tools in the Toolbox are handled by *CLC Main Workbench*. Note that this also applies to tools not running in batch mode (see above). All the analyses in the **Toolbox** are performed in a step-by-step procedure. First, you select elements for analyses, and then there are a number of steps where you can specify parameters (some of the analyses have no parameters, e.g. when translating DNA to RNA). The final step concerns the handling of the results of the analysis, and it is almost identical for all the analyses so we explain it in this section in general.

Figure 9.5: The last step of the analyses exemplified by Translate DNA to RNA.

In this step, shown in figure 9.5, you have two options:

- **Open.** This will open the result of the analysis in a view. This is the default setting.
- **Save.** This means that the result will not be opened but saved to a folder in the **Navigation Area**. If you select this option, click **Next** and you will see one more step where you can specify where to save the results (see figure 9.6). In this step, you also have the option of

creating a new folder or adding a location by clicking the buttons /  at the top of the dialog.

Figure 9.6: Specify a folder for the results of the analysis.

9.2.1 Table outputs

Some analyses also generate a table with results, and for these analyses the last step looks like figure 9.7.

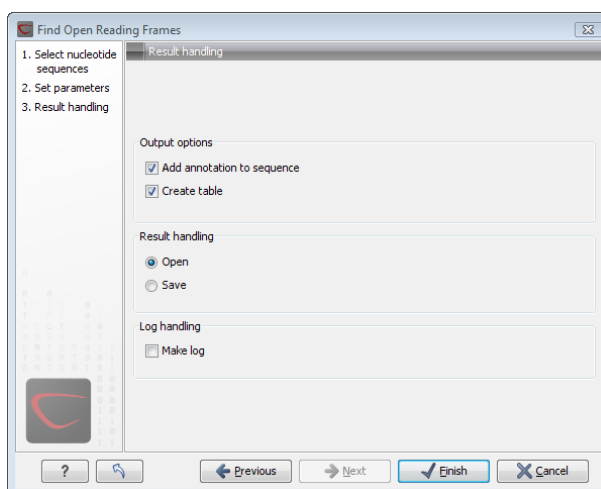

Figure 9.7: Analyses which also generate tables.

In addition to the **Open** and **Save** options you can also choose whether the result of the analysis should be added as annotations on the sequence or shown on a table. If both options are selected, you will be able to click the results in the table and the corresponding region on the sequence will be selected.

If you choose to add annotations to the sequence, they can be removed afterwards by clicking **Undo**  in the **Toolbar**.

9.2.2 Batch log

For some analyses, there is an extra option in the final step to create a log of the batch process (see e.g. figure 9.7). This log will be created in the beginning of the process and continually updated with information about the results. See an example of a log in figure 9.8. In this example, the log displays information about how many open reading frames were found.

Name	Description	Type	Time
AV738615	Found 10 reading frames		Fri Nov 17...
HJMDINJC	Found 5 reading frames		Fri Nov 17...
PERH1BA	Found 5 reading frames		Fri Nov 17...
PERH1BB	Found 7 reading frames		Fri Nov 17...
PERH2BA	Found 4 reading frames		Fri Nov 17...
PERH2BB	Found 7 reading frames		Fri Nov 17...
PERH2BD	Found 8 reading frames		Fri Nov 17...
PERH3BA	Found 3 reading frames		Fri Nov 17...
PERH3BC	Found 7 reading frames		Fri Nov 17...

Figure 9.8: An example of a batch log when finding open reading frames.

The log will either be saved with the results of the analysis or opened in a view with the results, depending on how you chose to handle the results.

10.3 Executing a workflow	196

The *CLC Main Workbench* provides a framework for creating, distributing, installing and running workflows. Workflows created in the Workbench can also be installed on a *CLC Genomics Server*.

A work flow consists of a series of tools where the output of one tool is connected as the input to another tool. In this way you can set up a workflow to go through for example read mapping, using the mapped reads as input for variant detection, and perform some filtering of the variant track. Once the workflow is set up, it can be installed (either in your own Workbench or on a Server or sent to a colleague) and you can then analyze a lot of samples using the same standard pipeline using the same reference data and parameters.

This chapter will first explain how to create a new workflow, and next go into details about the installation and execution of a workflow. For information about installing a workflow on the *CLC Genomics Server*, please see the user manual at <http://www.clcbio.com/usermanuals>. Note that the examples below are using tools from the *CLC Genomics Workbench* that are not available in the *CLC Main Workbench*. But the principles and workflow framework can be used in the same way with tools from *CLC Main Workbench*.

10.1 Creating a workflow

To create a workflow:

File | New | Workflow ()

This will open a new view with a blank screen where a new workflow can be created.

10.1.1 Adding workflow elements

First, click the **Add Element** () button at the top. This will bring up a dialog listing the elements and tools that can be added to a workflow (see figure 10.1).

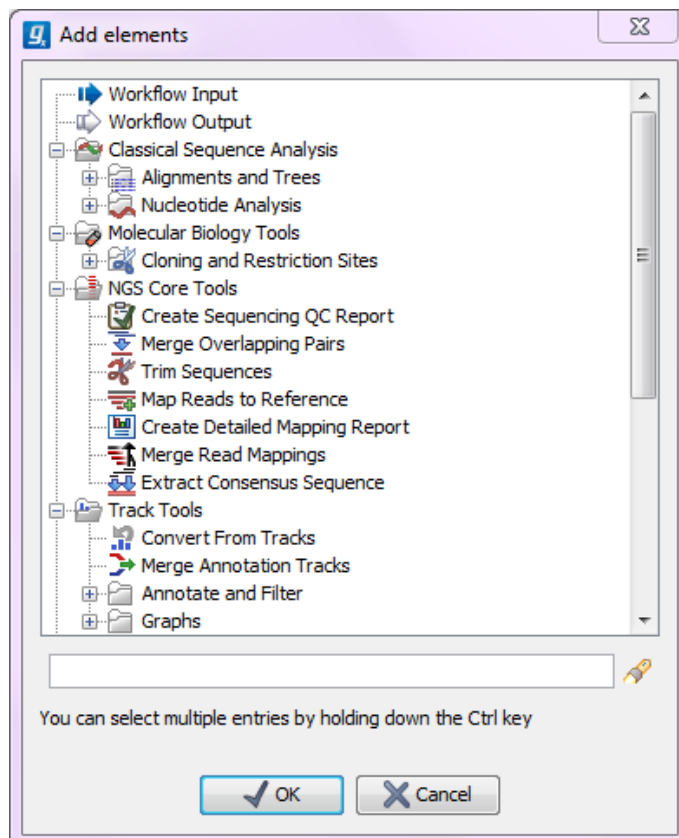

Figure 10.1: Adding elements in the workflow.

Most of these are tools from the Toolbox that can be used in the workflow. However, there are two special elements for input and output that will be explained in section 10.1.5.

You can select more elements in the Workflow by pressing Ctrl (⌘ on Mac) while selecting. Click OK when you have selected the relevant tools (you can always add more later).

You will now see each element represented in the editor (see figure 10.2).

Once added, you can move and re-arrange the elements by dragging with the mouse (grab the box with the name of the element).

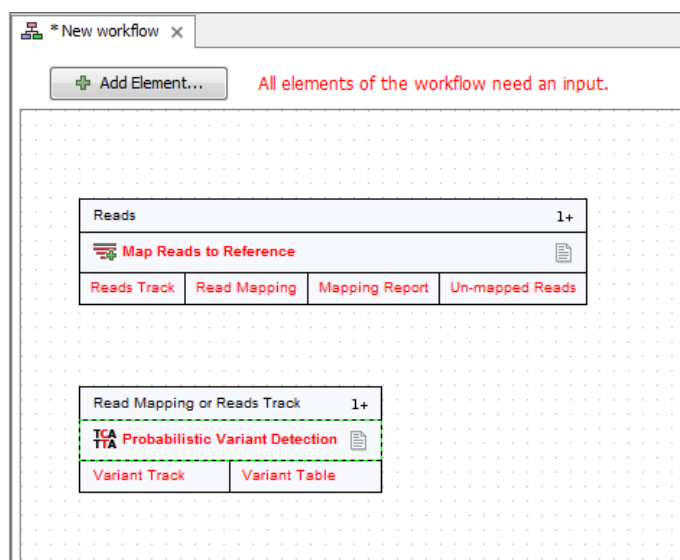

Figure 10.2: Read mapping and variant calling added to the workflow.

10.1.2 Configuring workflow elements

Each of the tools can be configured by right-clicking the name of the tool as shown in figure 10.3.

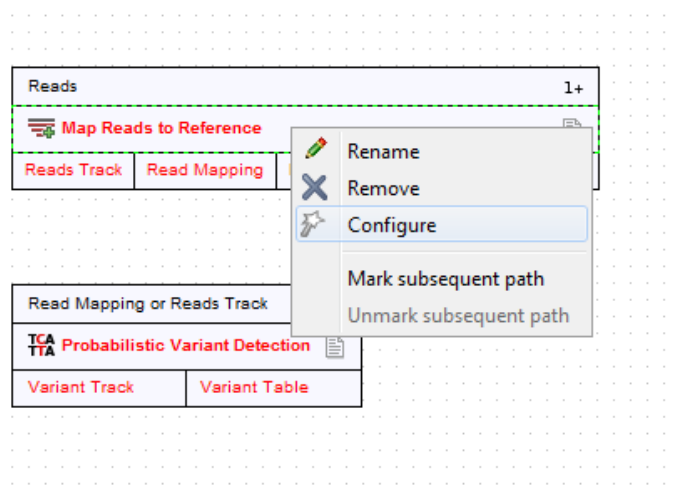

Figure 10.3: Configuring a tool.

First, there is an option to **Rename** the element, which can be useful to distinguish several copies of the same tool in the workflow. This name is also visible as part of the process description when the workflow is executed.

Second, you can **Configure** the tool. This can also be done by double-clicking the element. This will open a dialog with the options for setting parameters, select reference data etc. An example is shown in figure 10.4.

Click through the dialogs using **Next** and press **Finish** when you are done. This will save the parameter settings that will then be applied when the workflow is executed. Note that reference data are a bit special. In the example with the read mapper figure 10.3, you have to define a reference genome. This is done by pointing to data in the **Navigation Area**. If you distribute the

Figure 10.4: Configuring read mapper parameters.

workflow and install it in a different setting where this data is not accessible, the installation procedure will involve defining the new reference data to use (e.g. the reference genome sequence for read mapping). This is explained in more detail in section 10.2.

The lock icons in the dialog are used for specifying whether the parameter should be locked and unlocked as described in the next section.

Once an element has been configured, the workflow element gets a darker color to make it easy to see which elements have been configured.

10.1.3 Locking and unlocking parameters

Figure 10.5 shows the different stages in a workflow.

Figure 10.5: The life cycle of a workflow.

At the top, there is the workflow creation which is explained above. The workflow can then be installed in a Workbench or Server (explained in section 10.2). Subsequently, the workflow can be executed as any other tool in the **Toolbox**.

At the creation step, the workflow creator can specify which parameters should be locked or unlocked. If a parameter is locked, it means that it cannot be changed neither in the installation nor the execution step. The lock icons shown in figure 10.4 specifies whether the parameter should be open or locked.

If the parameter is left open, it is possible to adjust it as part of the installation (see section 10.2). Furthermore, it can also be locked at this stage.

Parameters that are left open both from the workflow creation and installation, will be available for adjustment when the workflow is executed.

Please note that data parameters per default are marked as unlocked. When installing the workflow somewhere else, the connection to the data needs to be re-established, and this is only possible when the parameter is unlocked. Data parameters should only be locked if they should not be set, or if the workflow will only be installed in a setting where there is access to the same data.

10.1.4 Connecting workflow elements

Figure 10.6 explains the different parts of a workflow element.

Figure 10.6: A workflow element consists of three parts: input, name of the tool, and output.

At the top of each element there is the description of the kind of input needed. In the right-hand side, a symbol specifies whether the element accepts multiple inputs, e.g. +1 means that more than one output can be connected, and no symbol means that only one can be connected. At the bottom of each element there are a number of small boxes that represent the different kinds of output that is produced. In the example with the read mapper shown in figure 10.2, the read mapper is able to produce a reads track, a report etc. Each of these boxes can be connected to further analysis in three ways:

- By dragging with the mouse from the output into the input box of the next element. This is shown in figure 10.7. A green border around the box will tell you when the mouse button can be released, and an arrow will connect the two elements (see figure 10.8).
- Right-clicking the output box will display a list of the possible elements that this output could be connected to. You can also right-click the input box of an element and connect this to a matching output of another element.
- Alternatively, if the element to connect to is not already added, you can right-click the output and choose **Add Element to be Connected**. This will bring up the dialog from figure 10.1, but only showing the tools that accepts this particular output. Selecting a tool will both add it to the workflow and connect with the output you selected. You can also add an upstream element of workflow in the same way by right-clicking the input box.

Figure 10.7: Dragging the reads track output with the mouse.

Figure 10.8: The reads track is now used for variant calling.

All the logic of combining output and input is based on matching the type of input. So the read mapper creates a reads track and a report as output. The variant caller accepts reads tracks as input but not mapping reports. This means that you will not be able to connect the mapping report to the variant caller.

10.1.5 Input and output

Besides connecting the elements together, you have to decide what the output of the workflow should be. This is done by right-clicking the output box of any tool and select **Use as Workflow Output** as shown in figure 10.9.

Figure 10.9: Selecting a workflow output.

By right-clicking you can enter a name for the output that will also be used for naming the result file that is generated. You can mark several outputs this way throughout the workflow. Note that no intermediate results are saved unless they are marked as workflow output¹.

¹When the workflow is executed, all the intermediate results are indeed saved temporarily but they are automatically deleted when the workflow is completed. If a part of the workflow fails, the intermediate results are not deleted.

In addition to output, you also have to specify where the data should go into the workflow. When the workflow is executed, the user will provide some input data, and this has to be passed to the first element(s) in the workflow. This can be done by right-clicking the input box of the first tool and choose **Connect to Workflow Input**. By dragging from the workflow input box to other input boxes you can have several tools use the input data directly. Note that only one kind of input data will be provided as input, so you cannot specify e.g. both a mapping and a sequence list as input.

10.1.6 Workflow validation

At the top of the view, there is a text with a status of the workflow (see figure 10.10). It will inform about the actions you need to take to finalize the workflow.

Figure 10.10: A workflow is constantly validated at the top of the view.

The following needs to be in place before a workflow can be executed:

- All input boxes need to be connected either to the workflow input or to the output of other tools.
- At least one output box from each tool needs to be connected to either a workflow output or to the input box of another tool.
- The workflow has to be **Saved** (📁).

Once these conditions are fulfilled, the **Start Test Run** button is enabled. Clicking this button will enable you to try running a data set through the workflow to test that it produces the expected results. If reference data has not been configured (see section 10.1.2), there will be a dialog asking for this as part of the test run.

10.1.7 Workflow creation helper tools

In the **Side Panel** of the workflow editor, there are some settings for the display of the workflow that can be useful to know (see figure 10.11):

Grid You can display a grid and control the spacing and color of the grid. Per default, the grid is shown, and the workflow elements snap to the grid when they are moved around.

View mode The elements of the workflow can be collapsed to allow a cleaner view and especially for large workflows this can be useful.

In addition to the settings in the **Side Panel**, you can right-click any element of the workflow and choose **Mark Subsequent Path**. This options is intended for use with complex workflows where all the workflow elements connected to the output of the element you selected will be high-lighted.

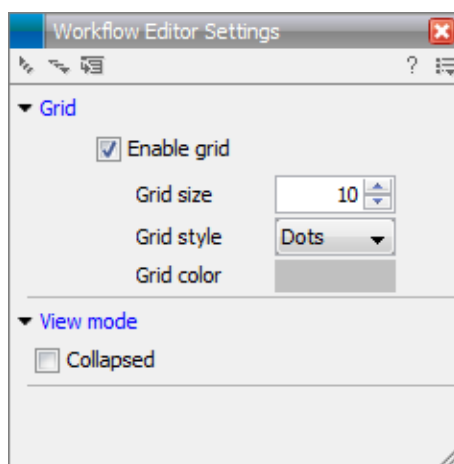

Figure 10.11: The Side Panel of the workflow editor.

10.1.8 Supported data flows

The current version of the workflow framework supports single-sample workflows. This means processing one sample through various analysis steps. When it comes to comparative analysis, this has to be done outside the workflow.

A typical example that would explain how this works is a trio analysis study where you want to compare variants found in a child with those from the mother and father. For this, you would create a workflow including mapping, variant detection, variant annotation and maybe some quality control. All three samples would be processed through this workflow in batch mode (see section 10.3). At the end, you can manually create a track list with all the relevant tracks (reads and variants) and run the trio analysis tool manually.

Since all the comparative tools are relatively quick, the bulk of the computation work can usually be incorporated into the workflow which can take care of the more tedious parts of the manual work involved.

CLC bio is planning further improvements to the workflow framework that allows you to model this kind of study as a workflow.

10.2 Distributing and installing workflows

Once the workflow has been configured, you can use the **Start Test Run** button (see section 10.1.6) to process data through the workflow, but the real power of the workflow is its ability to be distributed and installed in the **Toolbox** alongside the other tools that come with the *CLC Main Workbench*, as well as the ability to install the same workflow on a *CLC Genomics Server*. The mechanism for distributing the workflow is a workflow installer file which can be created from the workflow editor and distributed and installed in any Workbench or Server.

10.2.1 Creating a workflow installation file

At the top of the workflow editor, click the **Create Installer** button to bring up a dialog where you provide information about the workflow to be distributed (see an example with information from a CLC bio workflow in figure 10.12).

Figure 10.12: Workflow information for the installer.

Author information Providing name, email and organization of the author of the workflow. This will be visible for users installing the workflow and will enable them to look up the source of the workflow any time. The organization name is important because it is part of the workflow id (see more in section 10.2.3)

Workflow name The workflow name is based on the name used when saving the workflow in the **Navigation Area**. Renaming in the **Navigation Area** will also reflect when creating the installer. The workflow name is essential because it is used as part of the workflow id (see more in section 10.2.3).

Workflow description Provide a textual description of the workflow. This will be displayed for users when they have installed the workflow. Simple HTML tags are allowed (should be HTML 3.1 compatible, see <http://www.w3.org/TR/REC-html32>).

Icon An icon can be provided. This will show up in the installation overview and in the **Toolbox** once the workflow is installed. The icon should be a 16 x 16 pixels gif or png file. If the icon is larger, it will automatically be resized to fit 16 x 16 pixels.

Version A major and minor version can be provided.

Include original workflow file This will include the design file to be include with the installer. Once the workflow is installed in a workbench, you can extract the original workflow file and modify it.

Click **OK** and you will be asked to specify a name and a folder for saving the file. It will be saved as a .cpw file.

10.2.2 Installing a workflow

Workflows are installed in the workflow manager (for information about installing a workflow on the CLC Genomics Server, please see the user manual at <http://www.clcbio.com/usermanuals>):

Help | Workflows (🔧)

This will display a dialog listing the workflows installed. To install a new workflow, click **Install from File** and select a workflow .cpw file .

Once installed, it will appear in the workflow manager as shown in figure 10.13.

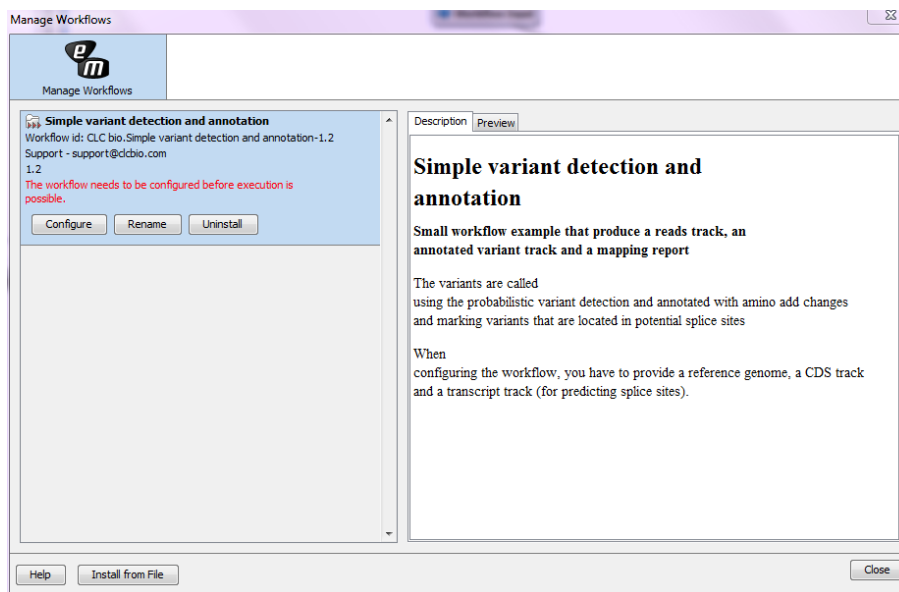

Figure 10.13: Workflow that needs to be configured.

To the right, you see the description that was entered when creating the workflow installer (see figure 10.12). You can switch the view to **Preview** and you will see a graphical representation of the workflow as shown in figure 10.14.

This workflow needs to be configured before it will work as indicated with the red label. The reason for this is that some parts of the workflow require reference data. As an example the read mapping needs a reference genome sequence. Since the workflow was created by a different user with access to a different data location, the pointer to the reference genome sequence needs to be re-established. No data is distributed as part of the workflow, so when installing the workflow in another context, reference data need to be present in order for the workflow to be properly configured.

Click **Configure** and you will be presented with a dialog listing all the reference data that need to be selected. An example is shown in figure 10.15.

This dialog also allows you to further lock parameters of the workflow (see more about locking in section 10.1.3).

If the workflow is intended to be executed on a server as well, it is important to select reference data that is located on the server.

In addition to the configuration option, it is also possible to rename the workflow. This will change

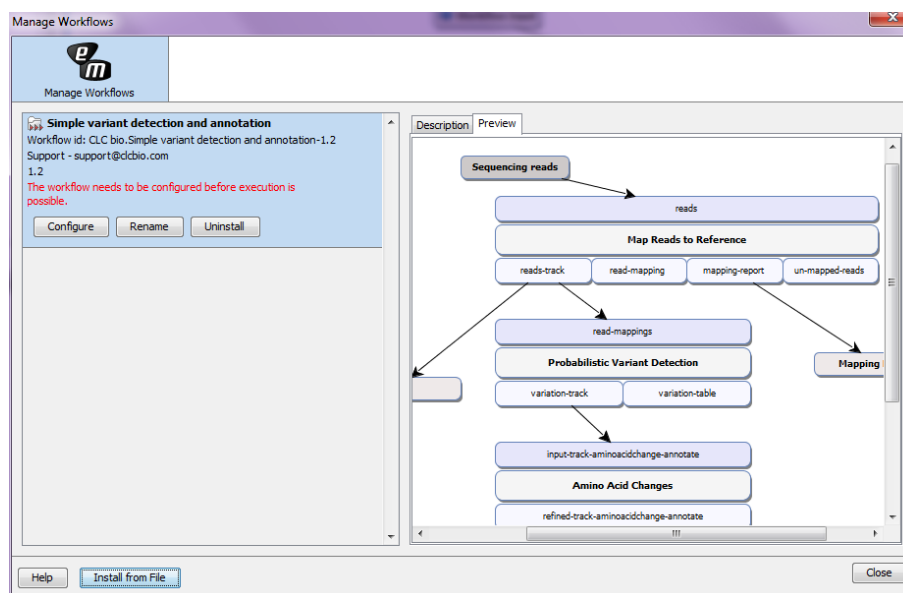

Figure 10.14: Preview of the workflow.

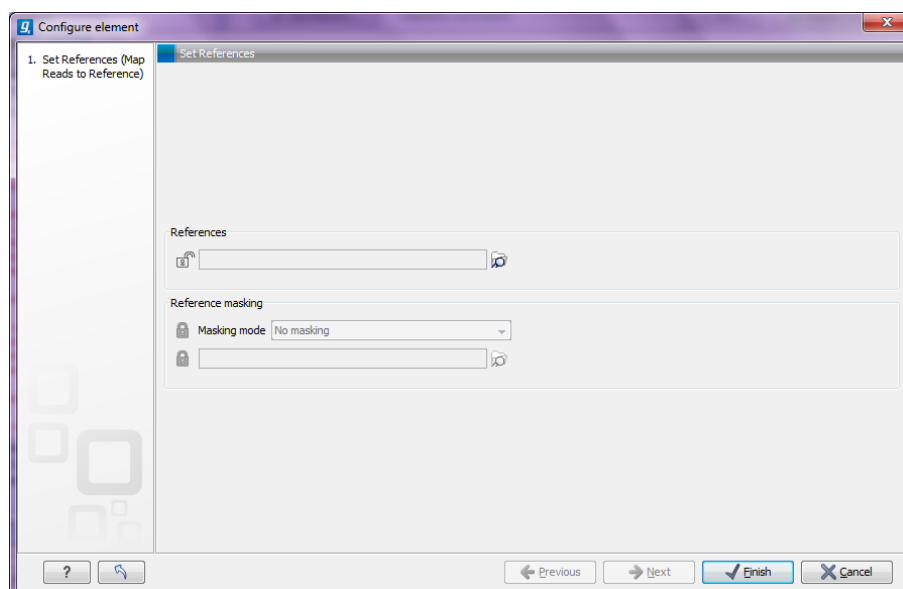

Figure 10.15: Configuring parameters for the workflow.

the name of the workflow in the **Toolbox**. The workflow id (see below) remains the same.

10.2.3 Workflow identification and versioning

A workflow has a version. The version is used to make it easy to distribute an improved version of the same workflow. To do this, create a new installer with an incremented version number. In order to install a new and updated version, the old one has to be uninstalled.

The way the *CLC Main Workbench* checks whether a workflow already exists in a previous version is by looking at the workflow id. The id is a combination of the organization name and the name of the workflow itself as it is shown in the dialog shown in figure 10.12. Once installed this information is also available in the workflow manager (in figure 10.13 this is CLC bio.Simple variant detection and annotation-1.2).

If you create two different workflows with the same name and using the same organization name when creating the installer, they cannot both be installed.

When new versions of the *CLC Main Workbench* are released, some of the tools that are part of a workflow may change. When this happens, the workflow may no longer be valid. This will happen both to the workflow configurations saved in the **Navigation Area** and the installed workflows. For the workflow configuration, you have to remove the invalid element and add the tool again. For installed workflows, there is no way to recover except asking the author of the workflow to update it and create a new version. We are working on improving this so that it becomes easier to recover when a new version is released.

10.3 Executing a workflow

Once installed and configured, a workflow will appear in the **Toolbox** under **Workflows** (📁). If an icon was provided with the workflow installer this will also be shown (see figure 10.16).

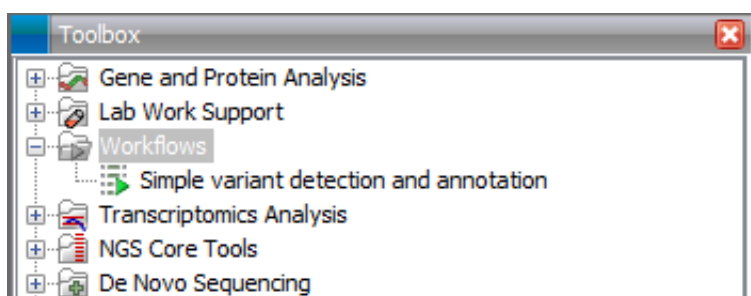

Figure 10.16: A workflow is installed and ready to be used.

The workflow is executed just as any other tool in the **Toolbox** by double-clicking or selecting it in the menu. This will open a dialog where you provide input data and with options to run the workflow in batch mode (see section 9.1).

If you are connected to a *CLC Genomics Server*, you will be presented with the option to run the workflow locally on the Workbench or on the Server. When you are selecting where to run the workflow, you should also see a message should there be any missing configurations. There are more details about running Workflows on the Server in the Server manual (<http://www.clcsupport.com/clcgenomicsserver/current/admin/index.php?manual=Workflows.html>).

When the workflow is started, you can see the log file with detailed information from each step in the process.

If the workflow is not properly configured, you will see that in the dialog when the workflow is started ².

²If the workflow uses a tool that is part of a plug-in, a missing plug-in can also be the reason why the workflow is not enabled. A workflow can also become outdated because the underlying tools have changed since the workflow was created (see section 10.2.3)

11.7.1 Graphical view of sequence lists	221
11.7.2 Sequence list table	222
11.7.3 Extract sequences	222

CLC Main Workbench offers five different ways of viewing and editing single sequences as described in the first five sections of this chapter. Furthermore, this chapter also explains how to create a new sequence and how to gather several sequences in a sequence list.

11.1 View sequence

When you double-click a sequence in the **Navigation Area**, the sequence will open automatically, and you will see the nucleotides or amino acids. The zoom options described in section 3.2 allow

you to e.g. zoom out in order to see more of the sequence in one view. There are a number of options for viewing and editing the sequence which are all described in this section. All the options described in this section also apply to alignments (further described in section 22.2).

11.1.1 Sequence settings in Side Panel

Each view of a sequence has a **Side Panel** located at the right side of the view (see figure 11.1).

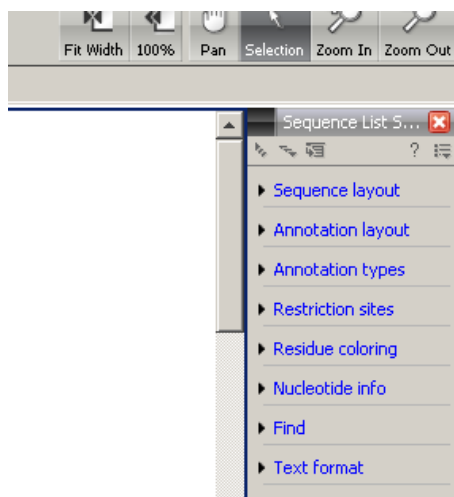

Figure 11.1: Overview of the Side Panel which is always shown to the right of a view.

When you make changes in the **Side Panel** the view of the sequence is instantly updated. To show or hide the **Side Panel**:

select the View | Ctrl + U

or **Click the (X) at the top right corner of the Side Panel to hide | Click the gray Side Panel button to the right to show**

Below, each group of settings will be explained. Some of the preferences are not the same for nucleotide and protein sequences, but the differences will be explained for each group of settings.

Note! When you make changes to the settings in the **Side Panel**, they are not automatically saved when you save the sequence. Click **Save/restore Settings** (☰) to save the settings (see section 5.6 for more information).

Sequence Layout

These preferences determine the overall layout of the sequence:

- **Spacing.** Inserts a space at a specified interval:
 - **No spacing.** The sequence is shown with no spaces.
 - **Every 10 residues.** There is a space every 10 residues, starting from the beginning of the sequence.
 - **Every 3 residues, frame 1.** There is a space every 3 residues, corresponding to the reading frame starting at the first residue.

- **Every 3 residues, frame 2.** There is a space every 3 residues, corresponding to the reading frame starting at the second residue.
- **Every 3 residues, frame 3.** There is a space every 3 residues, corresponding to the reading frame starting at the third residue.
- **Wrap sequences.** Shows the sequence on more than one line.
 - **No wrap.** The sequence is displayed on one line.
 - **Auto wrap.** Wraps the sequence to fit the width of the view, not matter if it is zoomed in our out (displays minimum 10 nucleotides on each line).
 - **Fixed wrap.** Makes it possible to specify when the sequence should be wrapped. In the text field below, you can choose the number of residues to display on each line.
- **Double stranded.** Shows both strands of a sequence (only applies to DNA sequences).
- **Numbers on sequences.** Shows residue positions along the sequence. The starting point can be changed by setting the number in the field below. If you set it to e.g. 101, the first residue will have the position of -100. This can also be done by right-clicking an annotation and choosing **Set Numbers Relative to This Annotation**.
- **Numbers on plus strand.** Whether to set the numbers relative to the positive or the negative strand in a nucleotide sequence (only applies to DNA sequences).
- **Follow selection.** When viewing the same sequence in two separate views, "Follow selection" will automatically scroll the view in order to follow a selection made in the other view.
- **Lock numbers.** When you scroll vertically, the position numbers remain visible. (Only possible when the sequence is not wrapped.)
- **Lock labels.** When you scroll horizontally, the label of the sequence remains visible.
- **Sequence label.** Defines the label to the left of the sequence.
 - Name (this is the default information to be shown).
 - Accession (sequences downloaded from databases like GenBank have an accession number).
 - Latin name.
 - Latin name (accession).
 - Common name.
 - Common name (accession).

Annotation Layout and Annotation Types

See section [11.3.1](#).

Restriction sites

See section [11.1.2](#).

Motifs

See section [15.7.1](#).

Residue coloring

These preferences make it possible to color both the residue letter and set a background color for the residue.

- **Non-standard residues.** For nucleotide sequences this will color the residues that are not C, G, A, T or U. For amino acids only B, Z, and X are colored as non-standard residues.
 - **Foreground color.** Sets the color of the letter. Click the color box to change the color.
 - **Background color.** Sets the background color of the residues. Click the color box to change the color.
- **Rasmol colors.** Colors the residues according to the Rasmol color scheme.
See <http://www.openrasmol.org/doc/rasmol.html>
 - **Foreground color.** Sets the color of the letter. Click the color box to change the color.
 - **Background color.** Sets the background color of the residues. Click the color box to change the color.
- **Polarity colors (only protein).** Colors the residues according to the following categories:
 - **Green** neutral, polar
 - **Black** neutral, nonpolar
 - **Red** acidic, polar
 - **Blue** basic ,polar
 - As with other options, you can choose to set or change the coloring for either the residue letter or its background:
 - * **Foreground color.** Sets the color of the letter. Click the color box to change the color.
 - * **Background color.** Sets the background color of the residues. Click the color box to change the color.
- **Trace colors (only DNA).** Colors the residues according to the color conventions of chromatogram traces: A=green, C=blue, G=black, and T=red.
 - **Foreground color.** Sets the color of the letter.
 - **Background color.** Sets the background color of the residues.

Nucleotide info

These preferences only apply to nucleotide sequences.

- **Translation.** Displays a translation into protein just below the nucleotide sequence. Depending on the zoom level, the amino acids are displayed with three letters or one letter.

- **Frame.** Determines where to start the translation.
 - * **ORF/CDS.** If the sequence is annotated, the translation will follow the CDS or ORF annotations. If annotations overlap, only one translation will be shown. If only one annotation is visible, the Workbench will attempt to use this annotation to mark the start and stop for the translation. In cases where this is not possible, the first annotation will be used (i.e. the one closest to the 5' end of the sequence).
 - * **Selection.** This option will only take effect when you make a selection on the sequence. The translation will start from the first nucleotide selected. Making a new selection will automatically display the corresponding translation. Read more about selecting in section [11.1.3](#).
 - * **+1 to -1.** Select one of the six reading frames.
 - * **All forward/All reverse.** Shows either all forward or all reverse reading frames.
 - * **All.** Select all reading frames at once. The translations will be displayed on top of each other.
- **Table.** The translation table to use in the translation. For more about translation tables, see section [16.5](#).
- **Only AUG start codons.** For most genetic codes, a number of codons can be start codons. Selecting this option only colors the AUG codons green.
- **Single letter codes.** Choose to represent the amino acids with a single letter instead of three letters.
- **Trace data.** See section [19.1](#).
- **Quality scores.** For sequencing data containing quality scores, the quality score information can be displayed along the sequence.
 - **Show as probabilities.** Converts quality scores to error probabilities on a 0-1 scale, i.e. not log-transformed.
 - **Foreground color.** Colors the letter using a gradient, where the left side color is used for low quality and the right side color is used for high quality. The sliders just above the gradient color box can be dragged to highlight relevant levels. The colors can be changed by clicking the box. This will show a list of gradients to choose from.
 - **Background color.** Sets a background color of the residues using a gradient in the same way as described above.
 - **Graph.** The quality score is displayed on a graph (Learn how to export the data behind the graph in section [7.4](#)).
 - * **Height.** Specifies the height of the graph.
 - * **Type.** The graph can be displayed as Line plot, Bar plot or as a Color bar.
 - * **Color box.** For Line and Bar plots, the color of the plot can be set by clicking the color box. For Colors, the color box is replaced by a gradient color box as described under Foreground color.
- **G/C content.** Calculates the G/C content of a part of the sequence and shows it as a gradient of colors or as a graph below the sequence.
 - **Window length.** Determines the length of the part of the sequence to calculate. A window length of 9 will calculate the G/C content for the nucleotide in question plus

the 4 nucleotides to the left and the 4 nucleotides to the right. A narrow window will focus on small fluctuations in the G/C content level, whereas a wider window will show fluctuations between larger parts of the sequence.

- **Foreground color.** Colors the letter using a gradient, where the left side color is used for low levels of G/C content and the right side color is used for high levels of G/C content. The sliders just above the gradient color box can be dragged to highlight relevant levels of G/C content. The colors can be changed by clicking the box. This will show a list of gradients to choose from.
- **Background color.** Sets a background color of the residues using a gradient in the same way as described above.
- **Graph.** The G/C content level is displayed on a graph (Learn how to export the data behind the graph in section 7.4).
 - * **Height.** Specifies the height of the graph.
 - * **Type.** The graph can be displayed as Line plot, Bar plot or as a Color bar.
 - * **Color box.** For Line and Bar plots, the color of the plot can be set by clicking the color box. For Colors, the color box is replaced by a gradient color box as described under Foreground color.

Protein info

These preferences only apply to proteins. The first nine items are different hydrophobicity scales and are described in section 17.5.2.

- **Kyte-Doolittle.** The Kyte-Doolittle scale is widely used for detecting hydrophobic regions in proteins. Regions with a positive value are hydrophobic. This scale can be used for identifying both surface-exposed regions as well as transmembrane regions, depending on the window size used. Short window sizes of 5-7 generally work well for predicting putative surface-exposed regions. Large window sizes of 19-21 are well suited for finding transmembrane domains if the values calculated are above 1.6 [Kyte and Doolittle, 1982]. These values should be used as a rule of thumb and deviations from the rule may occur.
- **Cornette.** Cornette *et al.* computed an optimal hydrophobicity scale based on 28 published scales [Cornette *et al.*, 1987]. This optimized scale is also suitable for prediction of alpha-helices in proteins.
- **Engelman.** The Engelman hydrophobicity scale, also known as the GES-scale, is another scale which can be used for prediction of protein hydrophobicity [Engelman *et al.*, 1986]. As the Kyte-Doolittle scale, this scale is useful for predicting transmembrane regions in proteins.
- **Eisenberg.** The Eisenberg scale is a normalized consensus hydrophobicity scale which shares many features with the other hydrophobicity scales [Eisenberg *et al.*, 1984].
- **Rose.** The hydrophobicity scale by Rose *et al.* is correlated to the average area of buried amino acids in globular proteins [Rose *et al.*, 1985]. This results in a scale which is not showing the helices of a protein, but rather the surface accessibility.
- **Janin.** This scale also provides information about the accessible and buried amino acid residues of globular proteins [Janin, 1979].

- **Hopp-Woods.** Hopp and Woods developed their hydrophobicity scale for identification of potentially antigenic sites in proteins. This scale is basically a hydrophilic index where apolar residues have been assigned negative values. Antigenic sites are likely to be predicted when using a window size of 7 [Hopp and Woods, 1983].
- **Welling.** [Welling et al., 1985] Welling et al. used information on the relative occurrence of amino acids in antigenic regions to make a scale which is useful for prediction of antigenic regions. This method is better than the Hopp-Woods scale of hydrophobicity which is also used to identify antigenic regions.
- **Kolaskar-Tongaonkar.** A semi-empirical method for prediction of antigenic regions has been developed [Kolaskar and Tongaonkar, 1990]. This method also includes information of surface accessibility and flexibility and at the time of publication the method was able to predict antigenic determinants with an accuracy of 75%.
- **Surface Probability.** Display of surface probability based on the algorithm by [Emini et al., 1985]. This algorithm has been used to identify antigenic determinants on the surface of proteins.
- **Chain Flexibility.** Display of backbone chain flexibility based on the algorithm by [Karplus and Schulz, 1985]. It is known that chain flexibility is an indication of a putative antigenic determinant.

Find

The Find function can also be invoked by pressing Ctrl + Shift + F (⌘ + Shift + F on Mac).

The Find function can be used for searching the sequence. Clicking the find button will search for the first occurrence of the search term. Clicking the find button again will find the next occurrence and so on. If the search string is found, the corresponding part of the sequence will be selected.

- **Search term.** Enter the text to search for. The search function does not discriminate between lower and upper case characters.
- **Sequence search.** Search the nucleotides or amino acids. For amino acids, the single letter abbreviations should be used for searching. The sequence search also has a set of advanced search parameters:
 - Include negative strand. This will search on the negative strand as well.
 - Treat ambiguous characters as wildcards in search term. If you search for e.g. ATN, you will find both ATG and ATC. If you wish to find literally exact matches for ATN (i.e. only find ATN - not ATG), this option should not be selected.
 - Treat ambiguous characters as wildcards in sequence. If you search for e.g. ATG, you will find both ATG and ATN. If you have large regions of Ns, this option should not be selected.

Note that if you enter a position instead of a sequence, it will automatically switch to position search.

- **Annotation search.** Searches the annotations on the sequence. The search is performed both on the labels of the annotations, but also on the text appearing in the tooltip that you

see when you keep the mouse cursor fixed. If the search term is found, the part of the sequence corresponding to the matching annotation is selected. Below this option you can choose to search for translations as well. Sequences annotated with coding regions often have the translation specified which can lead to undesired results.

- **Position search.** Finds a specific position on the sequence. In order to find an interval, e.g. from position 500 to 570, enter "500..570" in the search field. This will make a selection from position 500 to 570 (both included). Notice the two periods (..) between the start and end number (see section 11.3.2). If you enter positions including thousands separators like 123,345, the comma will just be ignored and it would be equivalent to entering 123345.
- **Include negative strand.** When searching the sequence for nucleotides or amino acids, you can search on both strands.
- **Name search.** Searches for sequence names. This is useful for searching sequence lists, mapping results and BLAST results.

This concludes the description of the **View Preferences**. Next, the options for selecting and editing sequences are described.

Text format

These preferences allow you to adjust the format of all the text in the view (both residue letters, sequence name and translations if they are shown).

- **Text size.** Five different sizes.
- **Font.** Shows a list of Fonts available on your computer.
- **Bold residues.** Makes the residues bold.

11.1.2 Restriction sites in the Side Panel

Please see section ??.

11.1.3 Selecting parts of the sequence

You can select parts of a sequence:

Click Selection () in Toolbar | Press and hold down the mouse button on the sequence where you want the selection to start | move the mouse to the end of the selection while holding the button | release the mouse button

Alternatively, you can search for a specific interval using the find function described above.

If you have made a selection and wish to adjust it:

drag the edge of the selection (you can see the mouse cursor change to a horizontal arrow

or **press and hold the Shift key while using the right and left arrow keys to adjust the right side of the selection.**

If you wish to select the entire sequence:

double-click the sequence name to the left

Selecting several parts at the same time (multiselect)

You can select several parts of sequence by holding down the **Ctrl** button while making selections. Holding down the **Shift** button lets you extend or reduce an existing selection to the position you clicked.

To select a part of a sequence covered by an annotation:

right-click the annotation | Select annotation

or **double-click the annotation**

To select a fragment between two restriction sites that are shown on the sequence:

double-click the sequence between the two restriction sites

(Read more about restriction sites in section [11.1.2.](#))

Open a selection in a new view

A selection can be opened in a new view and saved as a new sequence:

right-click the selection | Open selection in New View 

This opens the annotated part of the sequence in a new view. The new sequence can be saved by dragging the tab of the sequence view into the **Navigation Area**.

The process described above is also the way to manually translate coding parts of sequences (CDS) into protein. You simply translate the new sequence into protein. This is done by:

right-click the tab of the new sequence | Toolbox | Nucleotide Analysis  | **Translate to Protein** 

A selection can also be copied to the clipboard and pasted into another program:

make a selection | Ctrl + C (**⌘ + C on Mac**)

Note! The annotations covering the selection will not be copied.

A selection of a sequence can be edited as described in the following section.

11.1.4 Editing the sequence

When you make a selection, it can be edited by:

right-click the selection | Edit Selection 

A dialog appears displaying the sequence. You can add, remove or change the text and click **OK**. The original selected part of the sequence is now replaced by the sequence entered in the dialog. This dialog also allows you to paste text into the sequence using **Ctrl + V** (**⌘ + V on Mac**).

If you delete the text in the dialog and press **OK**, the selected text on the sequence will also be deleted. Another way to delete a part of the sequence is to:

right-click the selection | Delete Selection 

If you wish to only correct only one residue, this is possible by simply making the selection only cover one residue and then type the new residue. Another way to edit the sequence is by inserting a restriction site. See section 21.1.4.

11.1.5 Sequence region types

The various annotations on sequences cover parts of the sequence. Some cover an interval, some cover intervals with unknown endpoints, some cover more than one interval etc. In the following, all of these will be referred to as *regions*. Regions are generally illustrated by markings (often arrows) on the sequences. An arrow pointing to the right indicates that the corresponding region is located on the positive strand of the sequence. Figure 11.2 is an example of three regions with separate colors.

Figure 11.2: Three regions on a human beta globin DNA sequence (HUMHBB).

Figure 11.3 shows an artificial sequence with all the different kinds of regions.

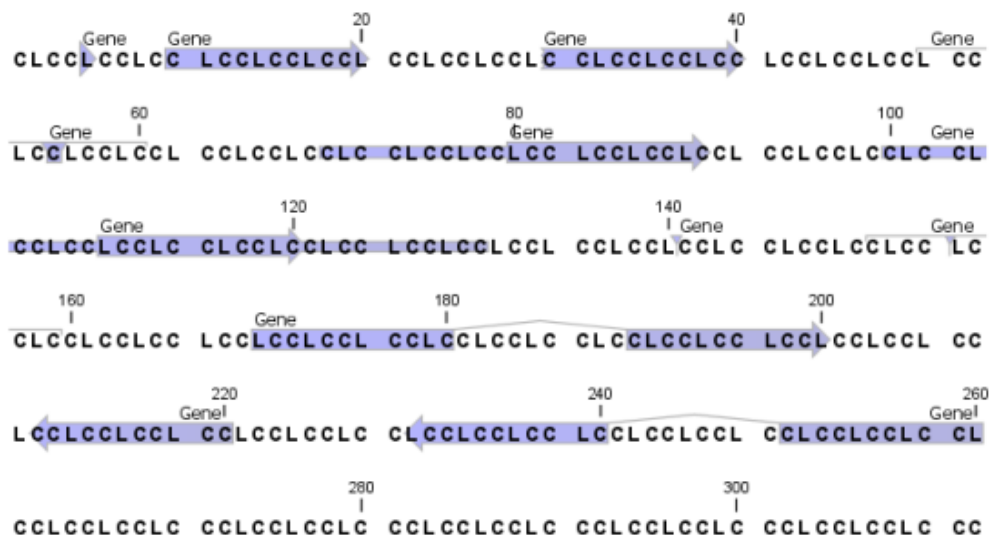

Figure 11.3: Region #1: A single residue, Region #2: A range of residues including both endpoints, Region #3: A range of residues starting somewhere before 30 and continuing up to and including 40, Region #4: A single residue somewhere between 50 and 60 inclusive, Region #5: A range of residues beginning somewhere between 70 and 80 inclusive and ending at 90 inclusive, Region #6: A range of residues beginning somewhere between 100 and 110 inclusive and ending somewhere between 120 and 130 inclusive, Region #7: A site between residues 140 and 141, Region #8: A site between two residues somewhere between 150 and 160 inclusive, Region #9: A region that covers ranges from 170 to 180 inclusive and 190 to 200 inclusive, Region #10: A region on negative strand that covers ranges from 210 to 220 inclusive, Region #11: A region on negative strand that covers ranges from 230 to 240 inclusive and 250 to 260 inclusive.

11.2 Circular DNA

A sequence can be shown as a circular molecule:

select a sequence in the Navigation Area | Show in the Toolbar | As Circular ()

or **If the sequence is already open | Click Show As Circular () at the lower left part of the view**

This will open a view of the molecule similar to the one in figure 11.4.

Figure 11.4: A molecule shown in a circular view.

This view of the sequence shares some of the properties of the linear view of sequences as described in section 11.1, but there are some differences. The similarities and differences are listed below:

- **Similarities:**

- The editing options.
- Options for adding, editing and removing annotations.
- **Restriction Sites, Annotation Types, Find** and **Text Format** preferences groups.

- **Differences:**

- In the **Sequence Layout** preferences, only the following options are available in the circular view: **Numbers on plus strand**, **Numbers on sequence** and **Sequence label**.
- You cannot zoom in to see the residues in the circular molecule. If you wish to see these details, split the view with a linear view of the sequence
- In the **Annotation Layout**, you also have the option of showing the labels as **Stacked**. This means that there are no overlapping labels and that all labels of both annotations and restriction sites are adjusted along the left and right edges of the view.

11.2.1 Using split views to see details of the circular molecule

In order to see the nucleotides of a circular molecule you can open a new view displaying a circular view of the molecule:

Press and hold the Ctrl button ( on Mac) | click Show Sequence () at the bottom of the view

This will open a linear view of the sequence below the circular view. When you zoom in on the linear view you can see the residues as shown in figure 11.5.

Figure 11.5: Two views showing the same sequence. The bottom view is zoomed in.

Note! If you make a selection in one of the views, the other view will also make the corresponding selection, providing an easy way for you to focus on the same region in both views.

11.2.2 Mark molecule as circular and specify starting point

You can mark a DNA molecule as circular by right-clicking its name in either the sequence view or the circular view. In the right-click menu you can also make a circular molecule linear. A circular molecule displayed in the normal sequence view, will have the sequence ends marked with a ».

The starting point of a circular sequence can be changed by:

make a selection starting at the position that you want to be the new starting point | right-click the selection | Move Starting Point to Selection Start

Note! This can only be done for sequence that have been marked as circular.

11.3 Working with annotations

Annotations provide information about specific regions of a sequence. A typical example is the annotation of a gene on a genomic DNA sequence.

Annotations derive from different sources:

- Sequences downloaded from databases like GenBank are annotated.
- In some of the data formats that can be imported into *CLC Main Workbench*, sequences can have annotations (GenBank, EMBL and Swiss-Prot format).
- The result of a number of analyses in *CLC Main Workbench* are annotations on the sequence (e.g. finding open reading frames and restriction map analysis).
- You can manually add annotations to a sequence (described in the section [11.3.2](#)).

Note! Annotations are included if you export the sequence in GenBank, Swiss-Prot, EMBL or CLC format. When exporting in other formats, annotations are not preserved in the exported file.

11.3.1 Viewing annotations

Annotations can be viewed in a number of different ways:

- As arrows or boxes in the sequence views:
 - Linear and circular view of sequences (👉) / (🔄).
 - Alignments (📊).
 - Graphical view of sequence lists (📋).
 - BLAST views (only the query sequence at the top can have annotations) (🔍).
 - Cloning editor (🔗).
 - Primer designer (both for single sequences and alignments) (📄) / (📊).
 - Contig/mapping view (🗺).
- In the table of annotations (📄).
- In the text view of sequences (📄).

In the following sections, these view options will be described in more detail.

In all the views except the text view (📄), annotations can be added, modified and deleted. This is described in the following sections.

View Annotations in sequence views

Figure 11.6 shows an annotation displayed on a sequence.

Figure 11.6: An annotation showing a coding region on a genomic dna sequence.

The various sequence views listed in section 11.3.1 have different default settings for showing annotations. However, they all have two groups in the **Side Panel** in common:

- **Annotation Layout**
- **Annotation Types**

The two groups are shown in figure 11.7.

In the **Annotation layout** group, you can specify how the annotations should be displayed (notice that there are some minor differences between the different sequence views):

- **Show annotations.** Determines whether the annotations are shown.

Figure 11.7: Changing the layout of annotations in the Side Panel.

- **Position.**

- **On sequence.** The annotations are placed on the sequence. The residues are visible through the annotations (if you have zoomed in to 100%).
- **Next to sequence.** The annotations are placed above the sequence.
- **Separate layer.** The annotations are placed above the sequence and above restriction sites (only applicable for nucleotide sequences).

- **Offset.** If several annotations cover the same part of a sequence, they can be spread out.

- **Piled.** The annotations are piled on top of each other. Only the one at front is visible.
- **Little offset.** The annotations are piled on top of each other, but they have been offset a little.
- **More offset.** Same as above, but with more spreading.
- **Most offset.** The annotations are placed above each other with a little space between. This can take up a lot of space on the screen.

- **Label.** The name of the annotation can shown as a label. Additional information about the sequence is shown if you place the mouse cursor on the annotation and keep it still.

- **No labels.** No labels are displayed.
 - **On annotation.** The labels are displayed in the annotation's box.
 - **Over annotation.** The labels are displayed above the annotations.
 - **Before annotation.** The labels are placed just to the left of the annotation.
 - **Flag.** The labels are displayed as flags at the beginning of the annotation.
 - **Stacked.** The labels are offset so that the text of all labels is visible. This means that there is varying distance between each sequence line to make room for the labels.
- **Show arrows.** Displays the end of the annotation as an arrow. This can be useful to see the orientation of the annotation (for DNA sequences). Annotations on the negative strand will have an arrow pointing to the left.
 - **Use gradients.** Fills the boxes with gradient color.

In the **Annotation Types** group, you can choose which kinds of annotations that should be displayed. This group lists all the types of annotations that are attached to the sequence(s) in the view. For sequences with many annotations, it can be easier to get an overview if you deselect the annotation types that are not relevant.

Unchecking the checkboxes in the **Annotation Layout** will not remove this type of annotations from the sequence - it will just hide them from the view.

Besides selecting which types of annotations that should be displayed, the **Annotation Types** group is also used to change the color of the annotations on the sequence. Click the colored square next to the relevant annotation type to change the color.

This will display a dialog with three tabs: Swatches, HSB, and RGB. They represent three different ways of specifying colors. Apply your settings and click **OK**. When you click **OK**, the color settings cannot be reset. The **Reset** function only works for changes made before pressing **OK**.

Furthermore, the **Annotation Types** can be used to easily browse the annotations by clicking the small button (▾) next to the type. This will display a list of the annotations of that type (see figure 11.8).

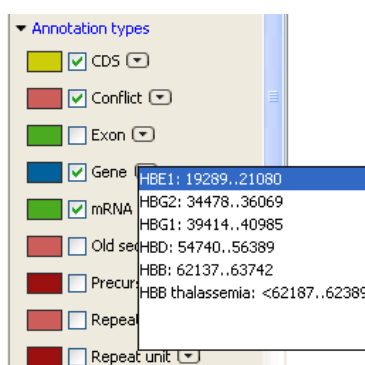

Figure 11.8: Browsing the gene annotations on a sequence.

Clicking an annotation in the list will select this region on the sequence. In this way, you can quickly find a specific annotation on a long sequence.

View Annotations in a table

Annotations can also be viewed in a table:

select the sequence in the Navigation Area | Show () | Annotation Table ()

or **If the sequence is already open | Click Show Annotation Table () at the lower left part of the view**

This will open a view similar to the one in figure 11.9).

Name	Type	Region	Qualifiers
chr X	Source	1..4314	/organism=Homo sapiens /mol_type=mRNA /db_xref="taxon:9606" /chromosome=X /map=Xq11.2-q12
STS	STS	1023..1097	/gene=AR /standard_name=GDB:600694 /db_xref="UniSTS:99252"
STS	STS	836..958	/gene=AR /standard_name=DXS7498 /db_xref="UniSTS:38944"

Figure 11.9: A table showing annotations on the sequence.

In the **Side Panel** you can show or hide individual annotation types in the table. E.g. if you only wish to see "gene" annotations, de-select the other annotation types so that only "gene" is selected.

Each row in the table is an annotation which is represented with the following information:

- **Name.**
- **Type.**
- **Region.**
- **Qualifiers.**

The Name, Type and Region for each annotation can be edited simply by double-clicking, typing the change directly, and pressing **Enter**.

This information corresponds to the information in the dialog when you edit and add annotations (see section 11.3.2).

You can benefit from this table in several ways:

- It provides an intelligible overview of all the annotations on the sequence.
- You can use the filter at the top to search the annotations. Type e.g. "UCP" into the filter and you will find all annotations which have "UCP" in either the name, the type, the region or the qualifiers. Combined with showing or hiding the annotation types in the **Side Panel**, this makes it easy to find annotations or a subset of annotations.
- You can copy and paste annotations, e.g. from one sequence to another.

- If you wish to edit many annotations consecutively, the double-click editing makes this very fast (see section 11.3.2).

11.3.2 Adding annotations

Adding annotations to a sequence can be done in two ways:

open the sequence in a sequence view (double-click in the Navigation Area) | make a selection covering the part of the sequence you want to annotate¹ | right-click the selection | Add Annotation (→)

or **select the sequence in the Navigation Area | Show (📄) | Annotations (📄) | right click anywhere in the annotation table | select New Annotation (→)**

This will display a dialog like the one in figure 11.10.

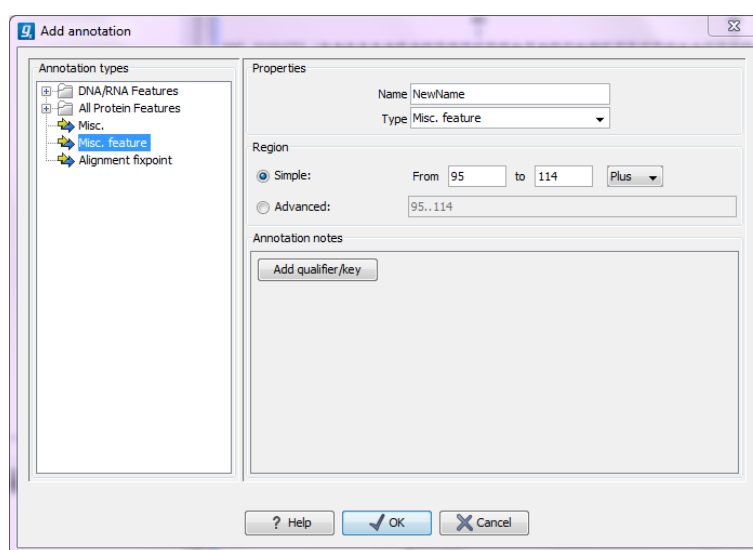

Figure 11.10: The Add Annotation dialog.

The left-hand part of the dialog lists a number of **Annotation types**. When you have selected an annotation type, it appears in **Type** to the right. You can also select an annotation directly in this list. Choosing an annotation type is mandatory. If you wish to use an annotation type which is not present in the list, simply enter this type into the **Type** field².

The right-hand part of the dialog contains the following text fields:

- **Name.** The name of the annotation which can be shown on the label in the sequence views. (Whether the name is actually shown depends on the **Annotation Layout** preferences, see section 11.3.1).
- **Type.** Reflects the left-hand part of the dialog as described above. You can also choose directly in this list or type your own annotation type.
- **Region.** If you have already made a selection, this field will show the positions of the selection. You can modify the region further using the conventions of DDBJ, EMBL

²Note that your own annotation types will be converted to "unsure" when exporting in GenBank format. As long as you use the sequence in CLC format, your own annotation type will be preserved

and GenBank. The following are examples of how to use the syntax (based on <http://www.ncbi.nlm.nih.gov/collab/FT/>):

- **467**. Points to a single residue in the presented sequence.
 - **340..565**. Points to a continuous range of residues bounded by and including the starting and ending residues.
 - **<345..500**. Indicates that the exact lower boundary point of a region is unknown. The location begins at some residue previous to the first residue specified (which is not necessarily contained in the presented sequence) and continues up to and including the ending residue.
 - **<1..888**. The region starts before the first sequenced residue and continues up to and including residue 888.
 - **1..>888**. The region starts at the first sequenced residue and continues beyond residue 888.
 - **(102.110)**. Indicates that the exact location is unknown, but that it is one of the residues between residues 102 and 110, inclusive.
 - **123^124**. Points to a site between residues 123 and 124.
 - **join(12..78,134..202)**. Regions 12 to 78 and 134 to 202 should be joined to form one contiguous sequence.
 - **complement(34..126)** Start at the residue complementary to 126 and finish at the residue complementary to residue 34 (the region is on the strand complementary to the presented strand).
 - **complement(join(2691..4571,4918..5163))**. Joins regions 2691 to 4571 and 4918 to 5163, then complements the joined segments (the region is on the strand complementary to the presented strand).
 - **join(complement(4918..5163),complement(2691..4571))**. Complements regions 4918 to 5163 and 2691 to 4571, then joins the complemented segments (the region is on the strand complementary to the presented strand).
- **Annotations**. In this field, you can add more information about the annotation like comments and links. Click the **Add qualifier/key** button to enter information. Select a qualifier which describes the kind of information you wish to add. If an appropriate qualifier is not present in the list, you can type your own qualifier. The pre-defined qualifiers are derived from the GenBank format. You can add as many qualifier/key lines as you wish by clicking the button. Redundant lines can be removed by clicking the delete icon (✖). The information entered on these lines is shown in the annotation table (see section 11.3.1) and in the yellow box which appears when you place the mouse cursor on the annotation. If you write a hyperlink in the **Key** text field, like e.g. "www.clcbio.com", it will be recognized as a hyperlink. Clicking the link in the annotation table will open a web browser.

Click **OK** to add the annotation.

Note! The annotation will be included if you export the sequence in GenBank, Swiss-Prot or CLC format. When exporting in other formats, annotations are not preserved in the exported file.

11.3.3 Edit annotations

To edit an existing annotation from within a sequence view:

right-click the annotation | Edit Annotation (👉)

This will show the same dialog as in figure 11.10, with the exception that some of the fields are filled out depending on how much information the annotation contains.

There is another way of quickly editing annotations which is particularly useful when you wish to edit several annotations.

To edit the information, simply double-click and you will be able to edit e.g. the name or the annotation type. If you wish to edit the qualifiers and double-click in this column, you will see the dialog for editing annotations.

Advanced editing of annotations

Sometimes you end up with annotations which do not have a meaningful name. In that case there is an advanced batch rename functionality:

Open the Annotation Table (👉) | select the annotations that you want to rename | right-click the selection | Advanced Rename

This will bring up the dialog shown in figure 11.11.

Figure 11.11: *The Advanced Rename dialog.*

In this dialog, you have two options:

- **Use this qualifier.** Use one of the qualifiers as name. A list of all qualifiers of all the selected annotations is shown. Note that if one of the annotations do not have the qualifier you have chosen, it will not be renamed. If an annotation has multiple qualifiers of the same type, the first is used for naming.
- **Use annotation type as name.** The annotation's type will be used as name (e.g. if you have an annotation of type "Promoter", it will get "Promoter" as its name by using this option).

A similar functionality is available for batch re-typing annotations is available in the right-click menu as well, in case your annotations are not typed correctly:

Open the Annotation Table (👉) | select the annotations that you want to retype | right-click the selection | Advanced Retype

This will bring up the dialog shown in figure 11.12.

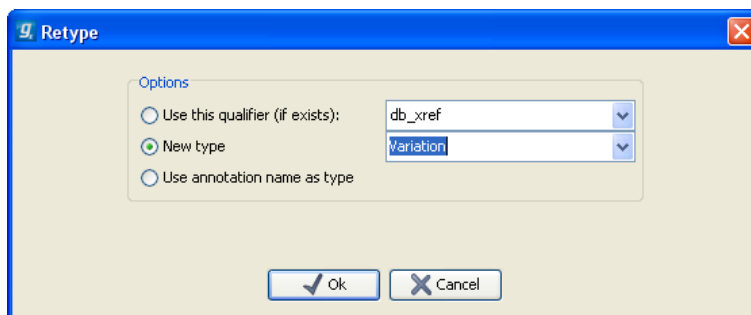

Figure 11.12: *The Advanced Retype dialog.*

In this dialog, you have two options:

- **Use this qualifier.** Use one of the qualifiers as type. A list of all qualifiers of all the selected annotations is shown. Note that if one of the annotations do not have the qualifier you have chosen, it will not be retyped. If an annotation has multiple qualifiers of the same type, the first is used for the new type.
- **New type.** You can select from a list of all the pre-defined types as well as enter your own annotation type. All the selected annotations will then get this type.
- **Use annotation name as type.** The annotation's name will be used as type (e.g. if you have an annotation named "Promoter", it will get "Promoter" as its type by using this option).

11.3.4 Removing annotations

Annotations can be hidden using the **Annotation Types** preferences in the **Side Panel** to the right of the view (see section 11.3.1). In order to completely remove the annotation:

right-click the annotation | Delete | Delete Annotation (🗑️)

If you want to remove all annotations of one type:

right-click an annotation of the type you want to remove | Delete | Delete Annotations of Type "type"

If you want to remove all annotations from a sequence:

right-click an annotation | Delete | Delete All Annotations

The removal of annotations can be undone using Ctrl + Z or Undo (↶) in the Toolbar.

If you have more sequences (e.g. in a sequence list, alignment or contig), you have two additional options:

right-click an annotation | Delete | Delete All Annotations from All Sequences

right-click an annotation | Delete | Delete Annotations of Type "type" from All Sequences

11.4 Element information

The normal view of a sequence (by double-clicking) shows the annotations as boxes along the sequence, but often there is more information available about sequences. This information is

available through the **Element info** view.

To view the sequence information:

select a sequence in the Navigation Area | Show (📄) in the Toolbar | Element info (📄)

This will display a view similar to fig 11.13.

Figure 11.13: The initial display of sequence info for the HUMHBB DNA sequence from the Example data.

All the lines in the view are headings, and the corresponding text can be shown by clicking the text.

- **Name.** The name of the sequence which is also shown in sequence views and in the **Navigation Area**.
- **Description.** A description of the sequence.
- **Comments.** The author's comments about the sequence.
- **Keywords.** Keywords describing the sequence.
- **Db source.** Accession numbers in other databases concerning the same sequence.
- **Gb Division.** Abbreviation of GenBank divisions. See section 3.3 in the GenBank release notes for a full list of GenBank divisions.
- **Length.** The length of the sequence.
- **Modification date.** Modification date from the database. This means that this date does not reflect your own changes to the sequence. See the history (section 8) for information about the latest changes to the sequence after it was downloaded from the database.
- **Organism.** Scientific name of the organism (first line) and taxonomic classification levels (second and subsequent lines).

The information available depends on the origin of the sequence. Sequences downloaded from database like NCBI and UniProt (see section 12) have this information. On the other hand, some sequence formats like fasta format do not contain this information.

Some of the information can be edited by clicking the blue **Edit** text. This means that you can add your own information to sequences that do not derive from databases.

Note that for other kinds of data, the **Element info** will only have **Name** and **Description**.

11.5 View as text

A sequence can be viewed as text without any layout and text formatting. This displays all the information about the sequence in the GenBank file format. To view a sequence as text:

select a sequence in the Navigation Area | Show in the Toolbar | As text

This way it is possible to see background information about e.g. the authors and the origin of DNA and protein sequences. Selections or the entire text of the **Sequence Text View** can be copied and pasted into other programs:

Much of the information is also displayed in the **Sequence info**, where it is easier to get an overview (see section 11.4.)

In the **Side Panel**, you find a search field for searching the text in the view.

11.6 Creating a new sequence

A sequence can either be imported, downloaded from an online database or created in the *CLC Main Workbench*. This section explains how to create a new sequence:

New (🔧) in the toolbar

Figure 11.14: Creating a sequence.

The **Create Sequence** dialog (figure 11.14) reflects the information needed in the GenBank format, but you are free to enter anything into the fields. The following description is a guideline for entering information about a sequence:

- **Name.** The name of the sequence. This is used for saving the sequence.
- **Common name.** A common name for the species.

- **Latin name.** The Latin name for the species.
- **Type.** Select between DNA, RNA and protein.
- **Circular.** Specifies whether the sequence is circular. This will open the sequence in a circular view as default. (applies only to nucleotide sequences).
- **Description.** A description of the sequence.
- **Keywords.** A set of keywords separated by semicolons (;).
- **Comments.** Your own comments to the sequence.
- **Sequence.** Depending on the type chosen, this field accepts nucleotides or amino acids. Spaces and numbers can be entered, but they are ignored when the sequence is created. This allows you to paste (Ctrl + V on Windows and ⌘ + V on Mac) in a sequence directly from a different source, even if the residue numbers are included. Characters that are not part of the IUPAC codes cannot be entered. At the top right corner of the field, the number of residues are counted. The counter does not count spaces or numbers.

Clicking **Finish** opens the sequence. It can be saved by clicking **Save**  or by dragging the tab of the sequence view into the **Navigation Area**.

11.7 Sequence Lists

The **Sequence List** shows a number of sequences in a tabular format or it can show the sequences together in a normal sequence view.

Having sequences in a sequence list can help organizing sequence data. The sequence list may originate from an NCBI search (chapter 12.1). Moreover, if a multiple sequence fasta file is imported, it is possible to store the data in a sequences list. A **Sequence List** can also be generated using a dialog, which is described here:

select two or more sequences | right-click the elements | New | Sequence List (≡)

This action opens a **Sequence List** dialog:

Figure 11.15: A Sequence List dialog.

The dialog allows you to select more sequences to include in the list, or to remove already chosen sequences from the list.

Clicking **Finish** opens the sequence list. It can be saved by clicking **Save** (📁) or by dragging the tab of the view into the **Navigation Area**.

Opening a Sequence list is done by:

right-click the sequence list in the Navigation Area | Show (📄) | Graphical Sequence List (📄) OR Table (📄)

The two different views of the same sequence list are shown in split screen in figure 11.16.

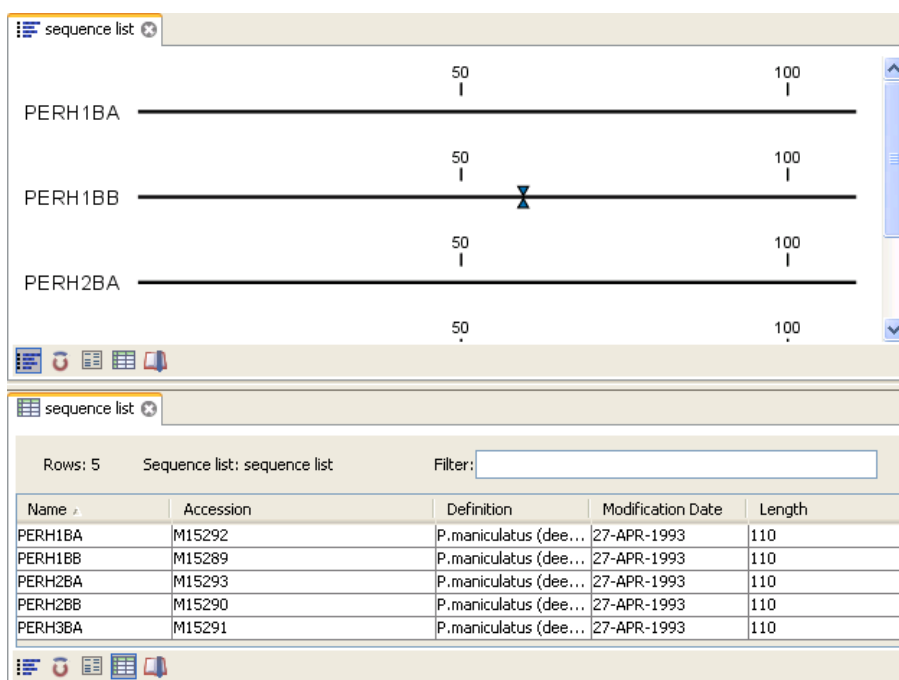

Figure 11.16: A sequence list containing multiple sequences can be viewed in either a table or in a graphical sequence list. The graphical view is useful for viewing annotations and the sequence itself, while the table view provides other information like sequence lengths, and the number of sequences in the list (number of Rows reported).

11.7.1 Graphical view of sequence lists

The graphical view of sequence lists is almost identical to the view of single sequences (see section 11.1). The main difference is that you now can see more than one sequence in the same view.

However, you also have a few extra options for sorting, deleting and adding sequences:

- To add extra sequences to the list, right-click an empty (white) space in the view, and select **Add Sequences**.
- To delete a sequence from the list, right-click the sequence's name and select **Delete Sequence**.

- To sort the sequences in the list, right-click the name of one of the sequences and select **Sort Sequence List by Name** or **Sort Sequence List by Length**.
- To rename a sequence, right-click the name of the sequence and select **Rename Sequence**.

11.7.2 Sequence list table

Each sequence in the table sequence list is displayed with:

- Name.
- Accession.
- Description.
- Modification date.
- Length.

The number of sequences in the list is reported as the number of Rows at the top of the table view.

Learn more about tables in section [C](#).

Adding and removing sequences from the list is easy: adding is done by dragging the sequence from another list or from the **Navigation Area** and drop it in the table. To delete sequences, simply select them and press **Delete** ()

You can also create a subset of the sequence list:

select the relevant sequences | right-click | Create New Sequence List

This will create a new sequence list, which only includes the selected sequences.

11.7.3 Extract sequences

It is possible to extract individual sequences from a sequence list in two ways. If the sequence list is opened in the tabular view, it is possible to drag (with the mouse) one or more sequences into the **Navigation Area**. This allows you to extract specific sequences from the entire list. Another option is to extract all sequences found in the list. This can also be done for:

- Alignments ()
- Contigs and read mappings ()
- Read mapping tables ()
- BLAST result ()
- BLAST overview tables ()
- RNA-Seq samples ()
- and of course sequence lists ()

For mappings and BLAST results, the main sequences (i.e. reference/consensus and query sequence) will not be extracted.

To extract the sequences:

Toolbox | General Sequence Analysis (📁) | Extract Sequences (🔍)

This will allow you to select the elements that you want to extract sequences from (see the list above). Clicking **Next** displays the dialog shown in 11.17.

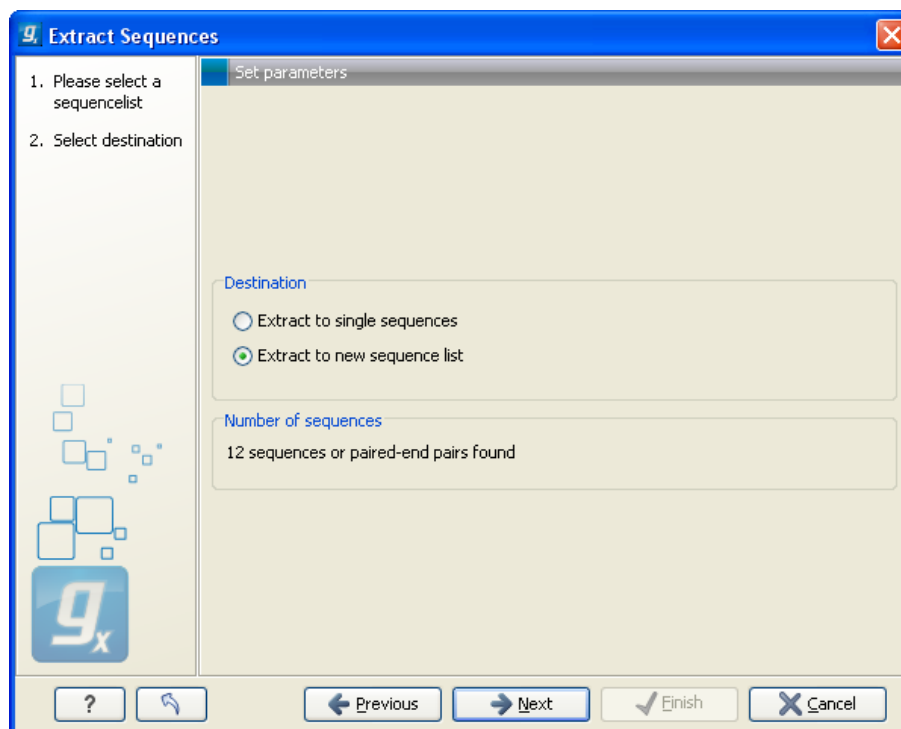

Figure 11.17: Choosing whether the extracted sequences should be placed in a new list or as single sequences.

Here you can choose whether the extracted sequences should be placed in a new list or extracted as single sequences. For sequence lists, only the last option makes sense, but for alignments, mappings and BLAST results, it would make sense to place the sequences in a list.

Below these options you can see the number of sequences that will be extracted.

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

CLC Main Workbench offers different ways of searching and downloading online data. You must be online when initiating and performing the following searches:

12.1 GenBank search

This section describes searches for sequences in GenBank - the **NCBI Entrez** database. The NCBI search view is opened in this way (figure 12.1):

Download | Search for Sequences at NCBI ()

or **Ctrl + B** (**⌘ + B** on Mac)

This opens the following view:

Figure 12.1: The GenBank search view.

12.1.1 GenBank search options

Conducting a search in the **NCBI Database** from *CLC Main Workbench* corresponds to conducting the search on NCBI's website. When conducting the search from *CLC Main Workbench*, the results are available and ready to work with straight away.

You can choose whether you want to search for nucleotide sequences or protein sequences.

As default, *CLC Main Workbench* offers one text field where the search parameters can be entered. Click **Add search parameters** to add more parameters to your search.

Note! The search is a "and" search, meaning that when adding search parameters to your search, you search for both (or all) text strings rather than "any" of the text strings.

You can append a wildcard character by checking the checkbox at the bottom. This means that you only have to enter the first part of the search text, e.g. searching for "genom" will find both "genomic" and "genome".

The following parameters can be added to the search:

- **All fields.** Text, searches in all parameters in the NCBI database at the same time.
- **Organism.** Text.
- **Description.** Text.
- **Modified Since.** Between 30 days and 10 years.
- **Gene Location.** Genomic DNA/RNA, Mitochondrion, or Chloroplast.
- **Molecule.** Genomic DNA/RNA, mRNA or rRNA.
- **Sequence Length.** Number for maximum or minimum length of the sequence.

- **Gene Name.** Text.

The search parameters are the most recently used. The **All fields** allows searches in all parameters in the NCBI database at the same time. **All fields** also provide an opportunity to restrict a search to parameters which are not listed in the dialog. E.g. writing `gene[Feature key] AND mouse` in **All fields** generates hits in the GenBank database which contains one or more genes and where 'mouse' appears somewhere in GenBank file. You can also write e.g. `CD9 NOT homo sapiens` in **All fields**.

Note! The 'Feature Key' option is only available in GenBank when searching for nucleotide sequences. For more information about how to use this syntax, see <http://www.ncbi.nlm.nih.gov/books/NBK3837/>

When you are satisfied with the parameters you have entered, click **Start search**.

Note! When conducting a search, no files are downloaded. Instead, the program produces a list of links to the files in the NCBI database. This ensures a much faster search.

12.1.2 Handling of GenBank search results

The search result is presented as a list of links to the files in the NCBI database. The **View** displays 50 hits at a time. This can be changed in the **Preferences** (see chapter 5). More hits can be displayed by clicking the **More...** button at the bottom right of the **View**.

Each sequence hit is represented by text in three columns:

- Accession.
- Description.
- Modification date.
- Length.

It is possible to exclude one or more of these columns by adjust the View preferences for the database search view. Furthermore, your changes in the View preferences can be saved. See section 5.6.

Several sequences can be selected, and by clicking the buttons in the bottom of the search view, you can do the following:

- Download and open, doesn't save the sequence.
- Download and save, lets you choose location for saving sequence.
- Open at NCBI, searches the sequence at NCBI's web page.

Double-clicking a hit will download and open the sequence. The hits can also be copied into the **View Area** or the **Navigation Area** from the search results by drag and drop, copy/paste or by using the right-click menu as described below.

Drag and drop from GenBank search results

The sequences from the search results can be opened by dragging them into a position in the **View Area**.

Note! A sequence is not saved until the **View** displaying the sequence is closed. When that happens, a dialog opens: Save changes of sequence x? (Yes or No).

The sequence can also be saved by dragging it into the **Navigation Area**. It is possible to select more sequences and drag all of them into the **Navigation Area** at the same time.

Download GenBank search results using right-click menu

You may also select one or more sequences from the list and download using the right-click menu (see figure 12.2). Choosing **Download and Save** lets you select a folder where the sequences are saved when they are downloaded. Choosing **Download and Open** opens a new view for each of the selected sequences.

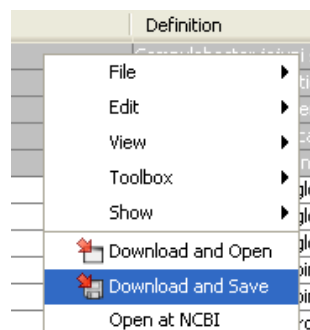

Figure 12.2: By right-clicking a search result, it is possible to choose how to handle the relevant sequence.

Copy/paste from GenBank search results

When using copy/paste to bring the search results into the **Navigation Area**, the actual files are downloaded from GenBank.

To copy/paste files into the **Navigation Area**:

select one or more of the search results | Ctrl + C (⌘ + C on Mac) | select a folder in the Navigation Area | Ctrl + V

Note! Search results are downloaded before they are saved. Downloading and saving several files may take some time. However, since the process runs in the background (displayed in the **Status bar**) it is possible to continue other tasks in the program. Like the search process, the download process can be stopped. This is done in the **Toolbox** in the **Processes** tab.

12.1.3 Save GenBank search parameters

The search view can be saved either using dragging the search tab and dropping it in the **Navigation Area** or by clicking **Save** (📁). When saving the search, only the parameters are saved - not the results of the search. This is useful if you have a special search that you perform from time to time.

Even if you don't save the search, the next time you open the search view, it will remember the parameters from the last time you did a search.

12.2 UniProt (Swiss-Prot/TrEMBL) search

This section describes searches in UniProt and the handling of search results. UniProt is a global database of protein sequences.

The UniProt search view (figure 12.3) is opened in this way:

Download | Search for Sequences in UniProt (🔍)

Figure 12.3: The UniProt search view.

12.2.1 UniProt search options

Conducting a search in **UniProt** from *CLC Main Workbench* corresponds to conducting the search on UniProt's website. When conducting the search from *CLC Main Workbench*, the results are available and ready to work with straight away.

Above the search fields, you can choose which database to search:

- **Swiss-Prot** This is believed to be the most accurate and best quality protein database available. All entries in the database has been curated manually and data are entered according to the original research paper.
- **TrEMBL** This database contain computer annotated protein sequences, thus the quality of the annotations is not as good as the Swiss-Prot database.

As default, *CLC Main Workbench* offers one text field where the search parameters can be entered. Click **Add search parameters** to add more parameters to your search.

Note! The search is a "and" search, meaning that when adding search parameters to your search, you search for both (or all) text strings rather than "any" of the text strings.

You can append a wildcard character by checking the checkbox at the bottom. This means that you only have to enter the first part of the search text, e.g. searching for "genom" will find both "genomic" and "genome".

The following parameters can be added to the search:

- **All fields.** Text, searches in all parameters in the UniProt database at the same time.
- **Organism.** Text.
- **Description.** Text.
- **Created Since.** Between 30 days and 10 years.
- **Feature.** Text.

The search parameters listed in the dialog are the most recently used. The **All fields** allows searches in all parameters in the UniProt database at the same time.

When you are satisfied with the parameters you have entered, click **Start search**.

Note! When conducting a search, no files are downloaded. Instead, the program produces a list of links to the files in the UniProt database. This ensures a much faster search.

12.2.2 Handling of UniProt search results

The search result is presented as a list of links to the files in the UniProt database. The **View** displays 50 hits at a time (can be changed in the **Preferences** (see chapter 5)). More hits can be displayed by clicking the **More...** button at the bottom right of the **View**. More hits can be displayed by clicking the **More...** button at the bottom left of the **View**.

Each sequence hit is represented by text in three columns:

- Accession
- Name
- Description
- Organism
- Length.

It is possible to exclude one or more of these columns by adjust the View preferences for the database search view. Furthermore, your changes in the View preferences can be saved. See section 5.6.

Several sequences can be selected, and by clicking the buttons in the bottom of the search view, you can do the following:

- Download and open, does not save the sequence.
- Download and save, lets you choose location for saving sequence.
- Open at UniProt, searches the sequence at UniProt's web page.

Double-clicking a hit will download and open the sequence. The hits can also be copied into the **View Area** or the **Navigation Area** from the search results by drag and drop, copy/paste or by using the right-click menu as described below.

Drag and drop from UniProt search results

The sequences from the search results can be opened by dragging them into a position in the **View Area**.

Note! A sequence is not saved until the **View** displaying the sequence is closed. When that happens, a dialog opens: Save changes of sequence x? (Yes or No).

The sequence can also be saved by dragging it into the **Navigation Area**. It is possible to select more sequences and drag all of them into the **Navigation Area** at the same time.

Download UniProt search results using right-click menu

You may also select one or more sequences from the list and download using the right-click menu (see figure 12.2). Choosing **Download and Save** lets you select a folder or location where the sequences are saved when they are downloaded. Choosing **Download and Open** opens a new view for each of the selected sequences.

Copy/paste from UniProt search results

When using copy/paste to bring the search results into the **Navigation Area**, the actual files are downloaded from UniProt.

To copy/paste files into the **Navigation Area**:

select one or more of the search results | Ctrl + C (⌘ + C on Mac) | select location or folder in the Navigation Area | Ctrl + V

Note! Search results are downloaded before they are saved. Downloading and saving several files may take some time. However, since the process runs in the background (displayed in the **Toolbox** under the **Processes** tab) it is possible to continue other tasks in the program. Like the search process, the download process can be stopped, paused, and resumed.

12.2.3 Save UniProt search parameters

The search view can be saved either using dragging the search tab and dropping it in the **Navigation Area** or by clicking **Save** (). When saving the search, only the parameters are saved - not the results of the search. This is useful if you have a special search that you perform from time to time.

Even if you don't save the search, the next time you open the search view, it will remember the parameters from the last time you did a search.

12.3 Search for structures at NCBI

This section describes searches for three dimensional structures from the NCBI structure database <http://www.ncbi.nlm.nih.gov/Structure/MMDB/mmdb.shtml>. For manipulating and visualization of the downloaded structures see section 14.

The NCBI search view is opened in this way:

Download | Search for structures at NCBI ()

or **Ctrl + B** (**⌘ + B** on Mac)

This opens the view shown in figure 12.4:

Figure 12.4: The structure search view.

12.3.1 Structure search options

Conducting a search in the **NCBI Database** from *CLC Main Workbench* corresponds to conducting search for structures on the NCBI's Entrez website. When conducting the search from *CLC Main Workbench*, the results are available and ready to work with straight away.

As default, *CLC Main Workbench* offers one text field where the search parameters can be entered. Click **Add search parameters** to add more parameters to your search.

Note! The search is a "AND" search, meaning that when adding search parameters to your search, you search for both (or all) text strings rather than "any" of the text strings.

You can append a wildcard character by clicking the checkbox at the bottom. This means that you only have to enter the first part of the search text, e.g. searching for "prot" will find both "protein" and "protease".

The following parameters can be added to the search:

- **All fields.** Text, searches in all parameters in the NCBI structure database at the same time.
- **Organism.** Text.
- **Author.** Text.
- **PdbAcc.** The accession number of the structure in the PDB database.

The search parameters are the most recently used. The **All fields** allows searches in all parameters in the database at the same time.

All fields also provide an opportunity to restrict a search to parameters which are not listed in the dialog. E.g. writing 'gene[Feature key] AND mouse' in **All fields** generates hits in the GenBank database which contains one or more genes and where 'mouse' appears somewhere in GenBank file. NB: the 'Feature Key' option is only available in GenBank when searching for nucleotide structures. For more information about how to use this syntax, see http://www.ncbi.nlm.nih.gov/entrez/query/static/help/Summary_Matrices.html#Search_Fields_and_Qualifiers

When you are satisfied with the parameters you have entered click **Start search**.

Note! When conducting a search, no files are downloaded. Instead, the program produces a list of links to the files in the NCBI database. This ensures a much faster search.

12.3.2 Handling of NCBI structure search results

The search result is presented as a list of links to the files in the NCBI database. The **View** displays 50 hits at a time (can be changed in the **Preferences** (see chapter 5). More hits can be displayed by clicking the **More...** button at the bottom right of the **View**.

Each structure hit is represented by text in three columns:

- Accession.
- Description.
- Resolution.
- Method.
- Protein chains
- Release date.

It is possible to exclude one or more of these columns by adjust the View preferences for the database search view. Furthermore, your changes in the View preferences can be saved. See section 5.6.

Several structures can be selected, and by clicking the buttons in the bottom of the search view, you can do the following:

- **Download and open.** Download and open immediately.
- **Download and save.** Download and save lets you choose location for saving structure.
- **Open at NCBI.** Open additional information on the selected structure at NCBI's web page.

Double-clicking a hit will download and open the structure. The hits can also be copied into the **View Area** or the **Navigation Area** from the search results by drag and drop, copy/paste or by using the right-click menu as described below.

Drag and drop from structure search results

The structures from the search results can be opened by dragging them into a position in the **View Area**.

Note! A structure is not saved until the **View** displaying the structure is closed. When that happens, a dialog opens: Save changes of structure x? (Yes or No).

The structure can also be saved by dragging it into the **Navigation Area**. It is possible to select more structures and drag all of them into the **Navigation Area** at the same time.

Download structure search results using right-click menu

You may also select one or more structures from the list and download using the right-click menu (see figure 12.5). Choosing **Download and Save** lets you select a folder or location where the structures are saved when they are downloaded. Choosing **Download and Open** opens a new view for each of the selected structures.

Figure 12.5: By right-clicking a search result, it is possible to choose how to handle the relevant structure.

The selected structures are not downloaded from the NCBI website but is downloaded from the RCSB Protein Data Bank <http://www.rcsb.org/pdb/home/home.do> in mmCIF format.

Copy/paste from structure search results

When using copy/paste to bring the search results into the **Navigation Area**, the actual files are downloaded.

To copy/paste files into the **Navigation Area**:

select one or more of the search results | Ctrl + C (⌘ + C on Mac) | select location or folder in the Navigation Area | Ctrl + V

Note! Search results are downloaded before they are saved. Downloading and saving several files may take some time. However, since the process runs in the background (displayed in the **Status bar**) it is possible to continue other tasks in the program. Like the search process, the download process can be stopped. This is done in the **Toolbox** in the **Processes** tab.

12.3.3 Save structure search parameters

The search view can be saved either using dragging the search tab and dropping it in the **Navigation Area** or by clicking **Save** (📁). When saving the search, only the parameters are saved

- not the results of the search. This is useful if you have a special search that you perform from time to time.

Even if you don't save the search, the next time you open the search view, it will remember the parameters from the last time you did a search.

12.4 Sequence web info

CLC Main Workbench provides direct access to web-based search in various databases and on the Internet using your computer's default browser. You can look up a sequence in the databases of NCBI and UniProt, search for a sequence on the Internet using Google and search for Pubmed references at NCBI. This is useful for quickly obtaining updated and additional information about a sequence.

The functionality of these search functions depends on the information that the sequence contains. You can see this information by viewing the sequence as text (see section 11.5). In the following sections, we will explain this in further detail.

The procedure for searching is identical for all four search options (see also figure 12.6):

Open a sequence or a sequence list | Right-click the name of the sequence | Web Info (🌐) | select the desired search function

Figure 12.6: Open webpages with information about this sequence.

This will open your computer's default browser searching for the sequence that you selected.

12.4.1 Google sequence

The Google search function uses the accession number of the sequence which is used as search term on <http://www.google.com>. The resulting web page is equivalent to typing the accession number of the sequence into the search field on <http://www.google.com>.

12.4.2 NCBI

The NCBI search function searches in GenBank at NCBI (<http://www.ncbi.nlm.nih.gov>) using an identification number (when you view the sequence as text it is the "GI" number). Therefore, the sequence file must contain this number in order to look it up at NCBI. All sequences downloaded from NCBI have this number.

12.4.3 PubMed References

The PubMed references search option lets you look up Pubmed articles based on references contained in the sequence file (when you view the sequence as text it contains a number of "PUBMED" lines). Not all sequence have these PubMed references, but in this case you will see a dialog and the browser will not open.

12.4.4 UniProt

The UniProt search function searches in the UniProt database (<http://www.ebi.uniprot.org>) using the accession number. Furthermore, it checks whether the sequence was indeed downloaded from UniProt.

12.4.5 Additional annotation information

When sequences are downloaded from GenBank they often link to additional information on taxonomy, conserved domains etc. If such information is available for a sequence it is possible to access additional accurate online information. If the db_xref identifier line is found as part of the annotation information in the downloaded GenBank file, it is possible to easily look up additional information on the NCBI web-site.

To access this feature, simply right click an annotation and see which databases are available.

For tracks, these links are also available in the track table.

13.5.7 I want to BLAST against my own sequence database, is this possible?	259
13.5.8 What you cannot get out of BLAST	260
13.5.9 Other useful resources	260

CLC Main Workbench offers to conduct BLAST searches on protein and DNA sequences. In short, a BLAST search identifies homologous sequences between your input (query) query sequence and a database of sequences [McGinnis and Madden, 2004]. BLAST (Basic Local Alignment Search

Tool), identifies homologous sequences using a heuristic method which finds short matches between two sequences. After initial match BLAST attempts to start local alignments from these initial matches.

If you are interested in the bioinformatics behind BLAST, there is an easy-to-read explanation of this in section 13.5.

With *CLC Main Workbench* there are two ways of performing BLAST searches: You can either have the BLAST process run on NCBI's BLAST servers (<http://www.ncbi.nlm.nih.gov/>) or perform the BLAST search on your own computer. The advantage of running the BLAST search on NCBI servers is that you have readily access to the most popular BLAST databases without having to download them to your own computer. The advantage of running BLAST on your own computer is that you can use your own sequence data, and that this can sometimes be faster and more reliable for big batch BLAST jobs

Figure 13.8 shows an example of a BLAST result in the *CLC Main Workbench*.

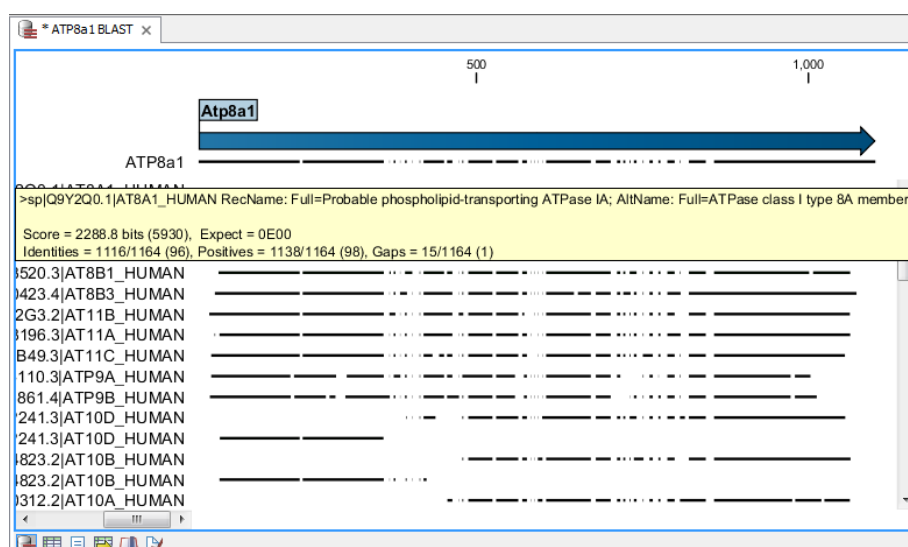

Figure 13.1: Display of the output of a BLAST search. At the top is there a graphical representation of BLAST hits with tool-tips showing additional information on individual hits. Below is a tabular form of the BLAST results.

13.1 Running BLAST searches

With the *CLC Main Workbench* there are two ways of performing BLAST searches: You can either have the BLAST process run on NCBI's BLAST servers (<http://www.ncbi.nlm.nih.gov/>) or you can perform the BLAST search on your own computer.

The advantage of running the BLAST search on NCBI servers is that you have readily access to the popular, and often very large, BLAST databases without having to download them to your own computer. The advantages of running BLAST on your own computer include that you can use your own sequence collections as blast databases, and that running big batch BLAST jobs can be faster and more reliable when done locally.

13.1.1 BLAST at NCBI

When running a BLAST search at the NCBI, the Workbench sends the sequences you select to the NCBI's BLAST servers. When the results are ready, they will be automatically downloaded and displayed in the Workbench. When you enter a large number of sequences for searching with BLAST, the Workbench automatically splits the sequences up into smaller subsets and sends one subset at the time to NCBI. This is to avoid exceeding any internal limits the NCBI places on the number of sequences that can be submitted to them for BLAST searching. The size of the subset created in the CLC software depends both on the number and size of the sequences.

To start a BLAST job to search your sequences against databases held at the NCBI:

Toolbox | BLAST  | **NCBI BLAST** 

Alternatively, use the keyboard shortcut: Ctrl+Shift+B for Windows and ⌘ +Shift+B on Mac OS.

This opens the dialog seen in figure 13.2

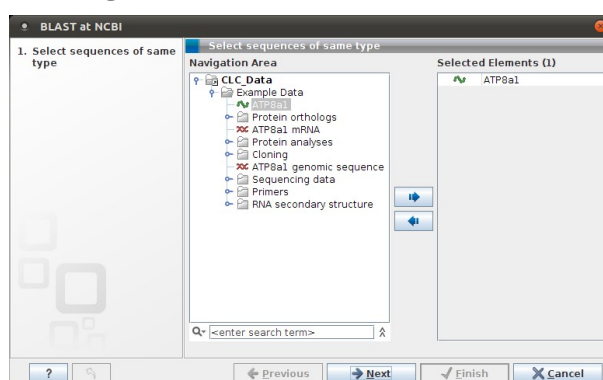

Figure 13.2: Choose one or more sequences to conduct a BLAST search with.

Select one or more sequences of the same type (either DNA or protein) and click **Next**.

In this dialog, you choose which type of BLAST search to conduct, and which database to search against. See figure 13.3. The databases at the NCBI listed in the dropdown box will correspond to the query sequence type you have, DNA or protein, and the type of blast search you have chosen to run. A complete list of these databases can be found in Appendix D. Here you can also read how to add additional databases available the NCBI to the list provided in the dropdown menu.

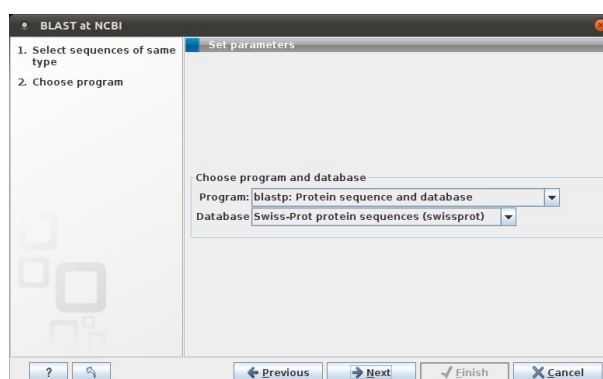

Figure 13.3: Choose a BLAST Program and a database for the search.

BLAST programs for DNA query sequences:

- **BLASTn: DNA sequence against a DNA database.** Used to look for DNA sequences with homologous regions to your nucleotide query sequence.
- **BLASTx: Translated DNA sequence against a Protein database.** Automatic translation of your DNA query sequence in six frames; these translated sequences are then used to search a protein database.
- **tBLASTx: Translated DNA sequence against a Translated DNA database.** Automatic translation of your DNA query sequence and the DNA database, in six frames. The resulting peptide query sequences are used to search the resulting peptide database. Note that this type of search is computationally intensive.

BLAST programs for protein query sequences:

- **BLASTp: Protein sequence against Protein database.** Used to look for peptide sequences with homologous regions to your peptide query sequence.
- **tBLASTn: Protein sequence against Translated DNA database.** Peptide query sequences are searched against an automatically translated, in six frames, DNA database.

If you search against the **Protein Data Bank protein** database homologous sequences are found to the query sequence, these can be downloaded and opened with the 3D view.

Click **Next**.

This window, see figure 13.4, allows you to choose parameters to tune your BLAST search, to meet your requirements.

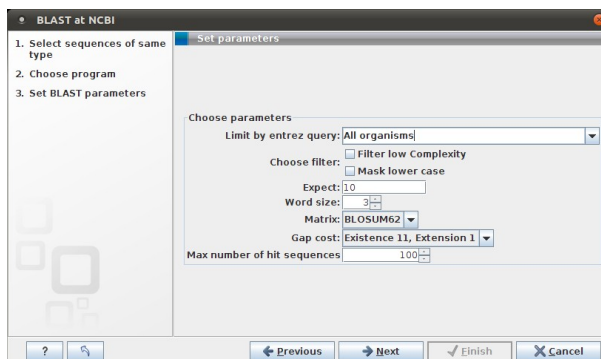

Figure 13.4: Parameters that can be set before submitting a BLAST search.

When choosing BLASTx or tBLASTx to conduct a search, you get the option of selecting a translation table for the genetic code. The standard genetic code is set as default. This setting is particularly useful when working with organisms or organelles that have a genetic code different from the standard genetic code.

The following description of BLAST search parameters is based on information from <http://www.ncbi.nlm.nih.gov/BLAST/blastcgihelp.shtml>.

- **Limit by Entrez query** BLAST searches can be limited to the results of an Entrez query against the database chosen. This can be used to limit searches to subsets of entries in the BLAST databases. Any terms can be entered that would normally be allowed in an Entrez search

session. More information about Entrez queries can be found at http://www.ncbi.nlm.nih.gov/books/NBK3837/#EntrezHelp.Entrez_Searching_Options. The syntax described there is the same as would be accepted in the CLC interface. Some commonly used Entrez queries are pre-entered and can be chosen in the drop down menu.

- **Choose filter**

- **Low-complexity.** Mask off segments of the query sequence that have low compositional complexity. Filtering can eliminate statistically significant, but biologically uninteresting reports from the BLAST output (e.g. hits against common acidic-, basic- or proline-rich regions), leaving the more biologically interesting regions of the query sequence available for specific matching against database sequences.
- **Mask lower case.** If you have a sequence with regions denoted in lower case, and other regions in upper case, then choosing this option would keep any of the regions in lower case from being considered in your BLAST search.

- **Expect.** The threshold for reporting matches against database sequences: the default value is 10, meaning that under the circumstances of this search, 10 matches are expected to be found merely by chance according to the stochastic model of Karlin and Altschul (1990). Details of how E-values are calculated can be found at the NCBI: <http://www.ncbi.nlm.nih.gov/BLAST/tutorial/Altschul-1.html> If the E-value ascribed to a match is greater than the EXPECT threshold, the match will not be reported. Lower EXPECT thresholds are more stringent, leading to fewer chance matches being reported. Increasing the threshold results in more matches being reported, but many may just matching by chance, not due to any biological similarity. Values of E less than one can be entered as decimals, or in scientific notation. For example, 0.001, 1e-3 and 10e-4 would be equivalent and acceptable values.

- **Word Size.** BLAST is a heuristic that works by finding word-matches between the query and database sequences. You may think of this process as finding "hot-spots" that BLAST can then use to initiate extensions that might lead to full-blown alignments. For nucleotide-nucleotide searches (i.e. "BLASTn") an exact match of the entire word is required before an extension is initiated, so that you normally regulate the sensitivity and speed of the search by increasing or decreasing the wordsize. For other BLAST searches non-exact word matches are taken into account based upon the similarity between words. The amount of similarity can be varied so that you normally uses just the wordsizes 2 and 3 for these searches.

- **Matrix.** A key element in evaluating the quality of a pairwise sequence alignment is the "substitution matrix", which assigns a score for aligning any possible pair of residues. The matrix used in a BLAST search can be changed depending on the type of sequences you are searching with (see the BLAST Frequently Asked Questions). Only applicable for protein sequences or translated DNA sequences.

- **Gap Cost.** The pull down menu shows the Gap Costs (Penalty to open Gap and penalty to extend Gap). Increasing the Gap Costs and Lambda ratio will result in alignments which decrease the number of Gaps introduced.

- **Max number of hit sequences.** The maximum number of database sequences, where BLAST found matches to your query sequence, to be included in the BLAST report.

The parameters you choose will affect how long BLAST takes to run. A search of a small database, requesting only hits that meet stringent criteria will generally be quite quick. Searching large databases, or allowing for very remote matches, will of course take longer.

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

13.1.2 BLAST a partial sequence against NCBI

You can search a database using only a part of a sequence directly from the sequence view:

select the sequence region to send to BLAST | right-click the selection | BLAST Selection Against NCBI 

This will go directly to the dialog shown in figure 13.3 and the rest of the options are the same as when performing a BLAST search with a full sequence.

13.1.3 BLAST against local data

Running BLAST searches on your local machine can have several advantages over running the searches remotely at the NCBI:

- It can be faster.
- It does not rely on having a stable internet connection.
- It does not depend on the availability of the NCBI BLAST blast servers.
- You can use longer query sequences.
- You use your own data sets to search against.

On a technical level, the *CLC Main Workbench* uses the NCBI's blast+ software (see <ftp://ftp.ncbi.nlm.nih.gov/blast/executables/blast+/LATEST/>). Thus, the results of using a particular data set to search the same database, with the same search parameters, would give the same results, whether run locally or at the NCBI.

There are a number of options for what you can search against:

- You create a database based on data already imported into your Workbench (see section 13.3.3)
- You can add pre-formatted databases (see section 13.3.1)
- You can use sequence data from the **Navigation Area** directly, without creating a database first.

To conduct a BLAST search:

or **Toolbox | BLAST**  | **Local BLAST** 

This opens the dialog seen in figure 13.5:

Select one or more sequences of the same type (DNA or protein) and click **Next**.

Figure 13.5: Choose one or more sequences to conduct a BLAST search.

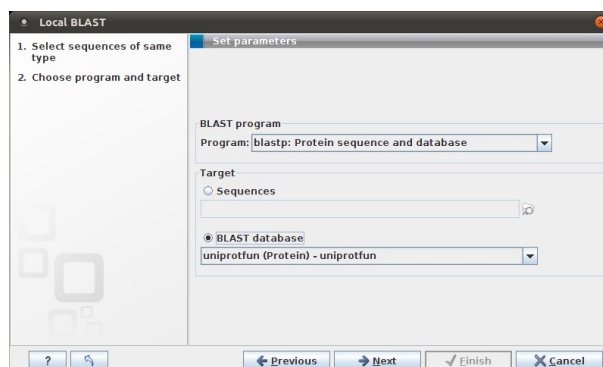

Figure 13.6: Choose a BLAST program and a target database.

This opens the dialog seen in figure 13.6:

At the top, you can choose between different BLAST programs. See section 13.1.1 for information about these methods.

You then specify the target database to use:

- **Sequences.** When you choose this option, you can use sequence data from the **Navigation Area** as database by clicking the **Browse and select** icon (). A temporary BLAST database will be created from these sequences and used for the BLAST search. It is deleted afterwards. If you want to be able to click in the BLAST result to retrieve the hit sequences from the BLAST database at a later point, you should *not* use this option; create a BLAST database first, see section 13.3.3.
- **BLAST Database.** Select a database already available in one of your designated BLAST database folders. Read more in section 13.4.

When a database or a set of sequences has been selected, click **Next**.

This opens the dialog seen in figure 13.7:

See section 13.1.1 for information about these limitations.

There is one setting available for local BLAST jobs that is not relevant for remote searches at the NCBI:

- **Number of processors.** You can specify the number of processors which should be used if your Workbench is installed on a multi-processor system.

Figure 13.7: Examples of parameters that can be set before submitting a BLAST search.

13.1.4 BLAST a partial sequence against a local database

You can search a database using only a part of a sequence directly from the sequence view:

select the region that you wish to BLAST | right-click the selection | BLAST Selection Against Local Database (🔍)

This will go directly to the dialog shown in figure 13.6 and the rest of the options are the same as when performing a BLAST search with a full sequence.

13.2 Output from BLAST searches

The output of a BLAST search is similar whether you have chosen to run your search locally or at the NCBI. If a single query sequence was used, then the results will show the hits found in that database with that single sequence. If more than one sequence was used to query a database, the default view of the results is a summary table, showing the description of the top database hit against each query sequence, and the number of hits found.

13.2.1 Graphical overview for each query sequence

Double clicking on a given row of a tabular blast table opens a graphical overview of the blast results for a particular query sequence, as shown in figure figure 13.8. In cases where only one sequence was entered into a BLAST search, such a graphical overview is the default output.

Figure 13.8 shows an example of a BLAST result for an individual query sequence in the *CLC Main Workbench*.

Detailed descriptions of the overview BLAST table and the graphical BLAST results view are described below.

13.2.2 Overview BLAST table

In the overview BLAST table for a multi-sequence blast search, as shown in figure 13.9, there is one row for each query sequence. Each row represents the BLAST result for this query sequence.

Double-clicking a row will open the BLAST result for this query sequence, allowing more detailed investigation of the result. You can also select one or more rows and click the **Open BLAST Output** button at the bottom of the view. Clicking the **Open Query Sequence** will open a sequence

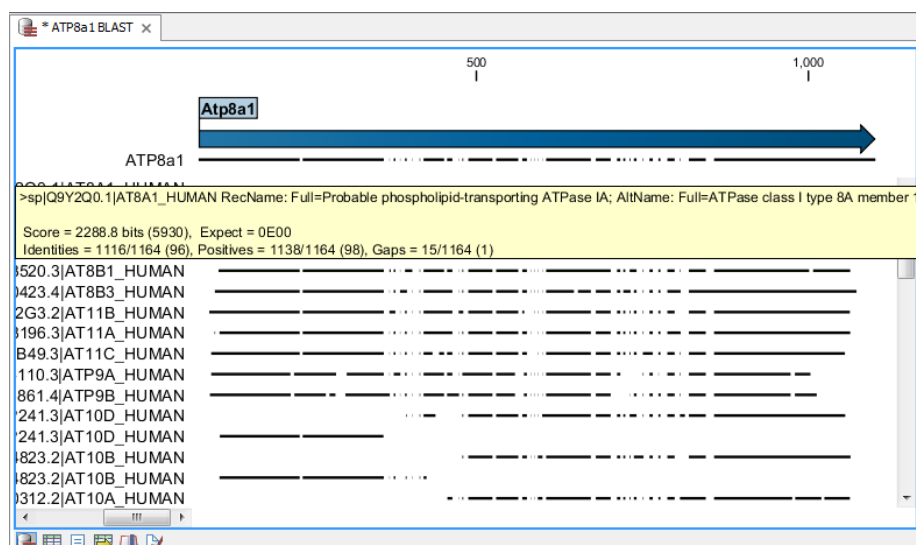

Figure 13.8: Default display of the output of a BLAST search for one query sequence. At the top is there a graphical representation of BLAST hits with tool-tips showing additional information on individual hits.

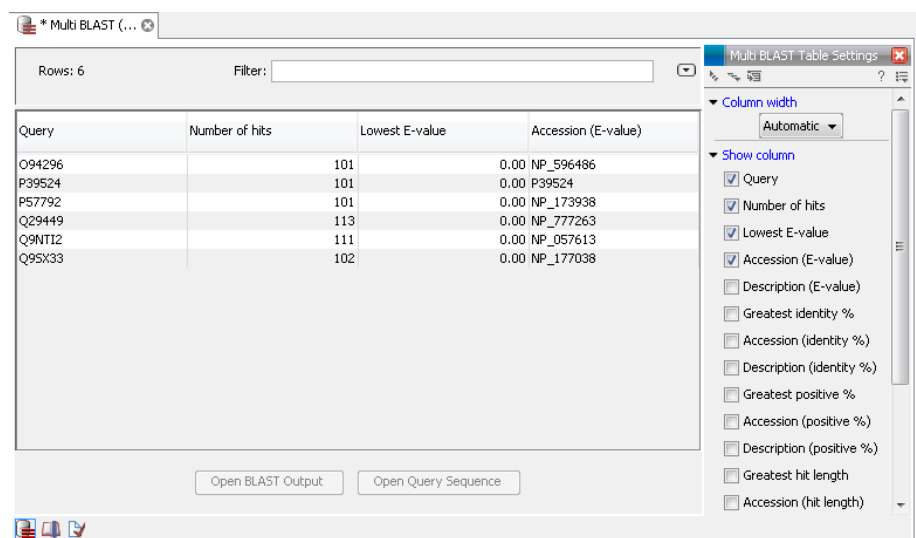

Figure 13.9: An overview BLAST table summarizing the results for a number of query sequences.

list with the selected query sequences. This can be useful in work flows where BLAST is used as a filtering mechanism where you can filter the table to include e.g. sequences that have a certain top hit and then extract those.

In the overview table, the following information is shown:

- Query: Since this table displays information about several query sequences, the first column is the name of the query sequence.
- Number of hits: The number of hits for this query sequence.
- For the following list, the value of the best hit is displayed together with accession number and description of this hit.
 - Lowest E-value

- Greatest identity %
- Greatest positive %
- Greatest hit length
- Greatest bit score

If you wish to save some of the BLAST results as individual elements in the **Navigation Area**, open them and click **Save As** in the **File** menu.

13.2.3 BLAST graphics

The **BLAST editor** shows the sequences hits which were found in the BLAST search. The hit sequences are represented by colored horizontal lines, and when hovering the mouse pointer over a BLAST hit sequence, a tooltip appears, listing the characteristics of the sequence. As default, the query sequence is fitted to the window width, but it is possible to zoom in the windows and see the actual sequence alignments returned from the BLAST server.

There are several settings available in the **BLAST Graphics** view.

- **BLAST Layout.** You can choose to **Gather sequences at top**. Enabling this option affects the view that is shown when scrolling horizontally along a BLAST result. If selected, the sequence hits which did not contribute to the visible part of the BLAST graphics will be omitted whereas the found BLAST hits will automatically be placed right below the query sequence.
- **Compactness:** You can control the level of sequence detail to be displayed:
 - **Not compact.** Full detail and spaces between the sequences.
 - **Low.** The normal settings where the residues are visible (when zoomed in) but with no extra spaces between.
 - **Medium.** The sequences are represented as lines and the residues are not visible. There is some space between the sequences.
 - **Compact.** Even less space between the sequences.
- **BLAST hit coloring.** You can choose whether to color hit sequences and you can adjust the coloring.
- **Coverage:** In the Alignment info in the Side Panel, you can visualize the number of hit sequences at a given position on the query sequence. The level of coverage is relative to the overall number of hits included in the result.
 - **Foreground color.** Colors the letters using a gradient, where the left side color is used for low coverage and the right side is used for maximum coverage.
 - **Background color.** Colors the background of the letters using a gradient, where the left side color is used for low coverage and the right side is used for maximum coverage
 - **Graph.** The coverage is displayed as a graph beneath the query sequence (Learn how to export the data behind the graph in section 7.4).
 - * **Height.** Specifies the height of the graph.
 - * **Type.** The graph can be displayed as Line plot, Bar plot or as a Color bar.

- * **Color box.** For Line and Bar plots, the color of the plot can be set by clicking the color box. If a Color bar is chosen, the color box is replaced by a gradient color box as described under Foreground color.

The remaining View preferences for BLAST Graphics are the same as those of alignments. See section [22.2](#).

Some of the information available in the tooltips is:

- **Name of sequence.** Here is shown some additional information of the sequence which was found. This line corresponds to the description line in GenBank (if the search was conducted on the nr database).
- **Score.** This shows the bit score of the local alignment generated through the BLAST search.
- **Expect.** Also known as the E-value. A low value indicates a homologous sequence. Higher E-values indicate that BLAST found a less homologous sequence.
- **Identities.** This number shows the number of identical residues or nucleotides in the obtained alignment.
- **Gaps.** This number shows whether the alignment has gaps or not.
- **Strand.** This is only valid for nucleotide sequences and show the direction of the aligned strands. Minus indicate a complementary strand.
- **Query.** This is the sequence (or part of the sequence) which you have used for the BLAST search.
- **Subjct (subject).** This is the sequence found in the database.

The numbers of the query and subject sequences refer to the sequence positions in the submitted and found sequences. If the subject sequence has number 59 in front of the sequence, this means that 58 residues are found upstream of this position, but these are not included in the alignment.

By right clicking the sequence name in the Graphical BLAST output it is possible to download the full hits sequence from NCBI with accompanying annotations and information. It is also possible to just open the actual hit sequence in a new view.

13.2.4 BLAST table

In addition to the graphical display of a BLAST result, it is possible to view the BLAST results in a tabular view. In the tabular view, one can get a quick and fast overview of the results. Here you can also select multiple sequences and download or open all of these in one single step. Moreover, there is a link from each sequence to the sequence at NCBI. These possibilities are either available through a right-click with the mouse or by using the buttons below the table.

If the **BLAST table** view was not selected in **Step 4** of the BLAST search, the table can be shown in the following way:

Click the Show BLAST Table button  at the bottom of the view

Hit	Description	E-value	Score	Bit score
1DXT-B	Chain B, Hemoglobin (Deoxy) Mutant With Additional M...	8.84E-67	629	246,899
1COH-B	Chain B, Alpha-Ferrous-Carbonmonoxy, Beta-Cobaltou...	3.36E-66	624	244,973
1Y85-B	Chain B, T-To-T(High) Quaternary Transitions In Human...	3.36E-66	624	244,973
1Y83-B	Chain B, T-To-T(High) Quaternary Transitions In Human...	7.48E-66	621	243,817
1DXU-B	Chain B, Hemoglobin (Deoxy) Mutant With Val 1 Replac...	7.48E-66	621	243,817
1NQP-B	Chain B, Crystal Structure Of Human Hemoglobin E At 1...	9.77E-66	620	243,432
1K1K-B	Chain B, Structure Of Mutant Human Carbonmonoxyhe...	9.77E-66	620	243,432

Figure 13.10: Display of the output of a BLAST search in the tabular view. The hits can be sorted by the different columns, simply by clicking the column heading.

Figure 13.10 is an example of a BLAST Table.

The BLAST Table includes the following information:

- **Query sequence.** The sequence which was used for the search.
- **Hit.** The Name of the sequences found in the BLAST search.
- **Id.** GenBank ID.
- **Description.** Text from NCBI describing the sequence.
- **E-value.** Measure of quality of the match. Higher E-values indicate that BLAST found a less homologous sequence.
- **Score.** This shows the score of the local alignment generated through the BLAST search.
- **Bit score.** This shows the bit score of the local alignment generated through the BLAST search. Bit scores are normalized, which means that the bit scores from different alignments can be compared, even if different scoring matrices have been used.
- **Hit start.** Shows the start position in the hit sequence
- **Hit end.** Shows the end position in the hit sequence.
- **Hit length.** The length of the hit.
- **Query start.** Shows the start position in the query sequence.
- **Query end.** Shows the end position in the query sequence.
- **Overlap.** Display a percentage value for the overlap of the query sequence and hit sequence. Only the length of the local alignment is taken into account and not the full length query sequence.
- **Identity.** Shows the number of identical residues in the query and hit sequence.
- **%Identity.** Shows the percentage of identical residues in the query and hit sequence.

- **Positive.** Shows the number of similar but not necessarily identical residues in the query and hit sequence.
- **%Positive.** Shows the percentage of similar but not necessarily identical residues in the query and hit sequence.
- **Gaps.** Shows the number of gaps in the query and hit sequence.
- **%Gaps.** Shows the percentage of gaps in the query and hit sequence.
- **Query Frame/Strand.** Shows the frame or strand of the query sequence.
- **Hit Frame/Strand.** Shows the frame or strand of the hit sequence.

In the **BLAST table** view you can handle the hit sequences. Select one or more sequences from the table, and apply one of the following functions.

- **Download and Open.** Download the full sequence from NCBI and opens it. If multiple sequences are selected, they will all open (if the same sequence is listed several times, only one copy of the sequence is downloaded and opened).
- **Download and Save.** Download the full sequence from NCBI and save it. When you click the button, there will be a save dialog letting you specify a folder to save the sequences. If multiple sequences are selected, they will all open (if the same sequence is listed several times, only one copy of the sequence is downloaded and opened).
- **Open at NCBI.** Opens the corresponding sequence(s) at GenBank at NCBI. Here is stored additional information regarding the selected sequence(s). The default Internet browser is used for this purpose.
- **Open structure.** If the hit sequence contain structure information, the sequence is opened in a text view or a 3D view (3D view in *CLC Main Workbench* or *CLC Genomics Workbench*).

The hits can be sorted by the different columns, simply by clicking the column heading. In cases where individual rows have been selected in the table, the selected rows will still be selected after sorting the data.

You can do a text-based search in the information in the BLAST table by using the filter at the upper right part of the view. In this way you can search for e.g. species or other information which is typically included in the "Description" field.

The table is integrated with the graphical view described in section 13.2.3 so that selecting a hit in the table will make a selection on the corresponding sequence in the graphical view.

13.3 Local BLAST databases

BLAST databases on your local system can be made available for searches via your *CLC Main Workbench*, (section 13.3.1). To make adding databases even easier, you can download pre-formatted BLAST databases from the NCBI from within your *CLC Main Workbench*, (section 13.3.2). You can also easily create your own local blast databases from sequences within your *CLC Main Workbench*, (section 13.3.3).

13.3.1 Make pre-formatted BLAST databases available

To use databases that have been downloaded or created outside the Workbench, you can either

- Put the database files in one of the locations defined in the BLAST database manager (see section 13.4)
- Add the location where your BLAST databases are stored using the BLAST database manager (see section 13.4). See figure 13.14.

13.3.2 Download NCBI pre-formatted BLAST databases

Many popular pre-formatted databases are available for download from the NCBI. You can download any of the databases available from the list at <ftp://ftp.ncbi.nlm.nih.gov/blast/db/> from within your *CLC Main Workbench*.

You must be connected to the internet to use this tool.

If you choose:

or **Toolbox | BLAST** () | **Download BLAST Databases** ()

a window like the one in figure 13.11 pops up showing you the list of databases available for download.

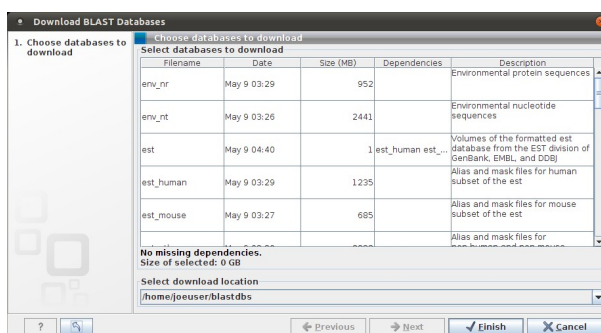

Figure 13.11: Choose from pre-formatted BLAST databases at the NCBI available for download.

In this window, you can see the names of the databases, the date they were made available for download on the NCBI site, the size of the files associated with that database, and a brief description of each database. You can also see whether the database has any dependencies. This aspect is described below.

You can also specify which of your database locations you would like to store the files in. Please see the **Manage BLAST Databases** section for more on this (section 13.4).

There are two very important things to note if you wish to take advantage of this tool.

- Many of the databases listed are very large. Please make sure you have room for them. If you are working on a shared system, we recommend you discuss your plans with your system administrator and fellow users.
- Some of the databases listed are dependent on others. This will be listed in the **Dependencies** column of the **Download BLAST Databases** window. This means that while

the database you are interested in may seem very small, it may require that you also download a very big database on which it depends.

An example of the second item above is *Swissprot*. To download a database from the NCBI that would allow you to search just Swissprot entries, you need to download the whole *nr* database in addition to the entry for Swissprot.

13.3.3 Create local BLAST databases

In the *CLC Main Workbench* you can create a local database that you can use for local BLAST searches. You can specify a location on your computer to save the BLAST database files to. The Workbench will list the BLAST databases found in these locations when you set up a local BLAST search (see section 13.1.3).

DNA, RNA, and protein sequences located in the **Navigation Area** can be used to create BLAST databases from. Any given BLAST database can only include one molecule type. If you wish to use a pre-formatted BLAST database instead, see section 13.3.1.

To create a BLAST database, go to:

Toolbox | BLAST (📁) | Create BLAST Database (👤+)

This opens the dialog seen in figure 13.12.

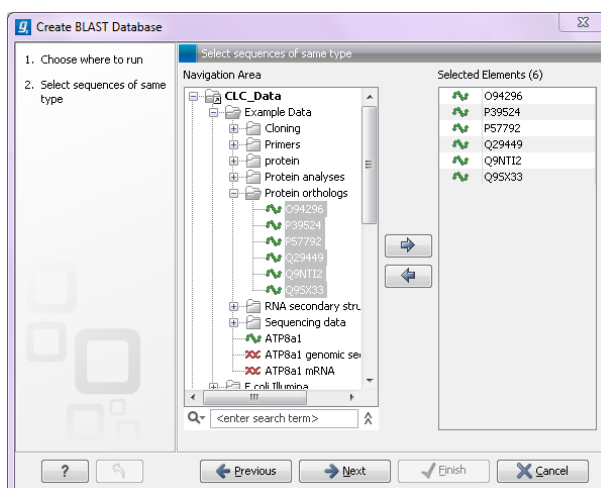

Figure 13.12: Add sequences for the BLAST database.

Select sequences or sequence lists you wish to include in your database and click **Next**.

In the next dialog, shown in figure 13.13, you provide the following information:

- **Name.** The name of the BLAST database. This name will be used when running BLAST searches and also as the base file name for the BLAST database files.
- **Description.** You can add more details to describe the contents of the database.
- **Location.** You can select the location to save the BLAST database files to. You can add or change the locations in this list using the **Manage BLAST Databases** tool, see section 13.4.

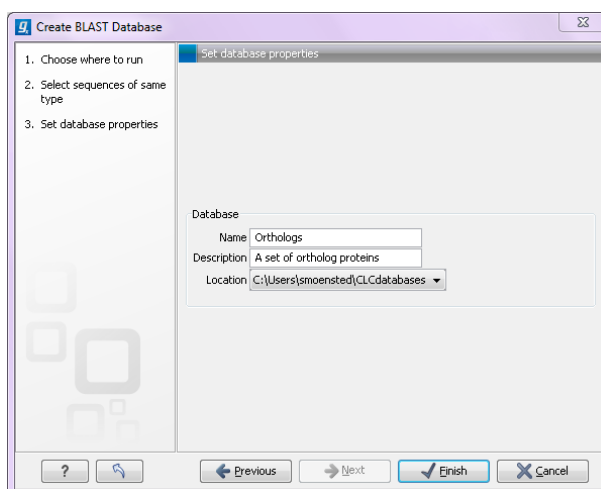

Figure 13.13: Providing a name and description for the database, and the location to save the files to.

Click **Finish** to create the BLAST database. Once the process is complete, the new database will be available in the **Manage BLAST Databases** dialog, see section 13.4, and when running local BLAST (see section 13.1.3).

13.4 Manage BLAST databases

The BLAST database available as targets for running local BLAST searches (see section 13.1.3) can be managed through the Manage BLAST Databases dialog (see figure 13.14):

Toolbox | BLAST (📄) | Manage BLAST Databases (🗄️)

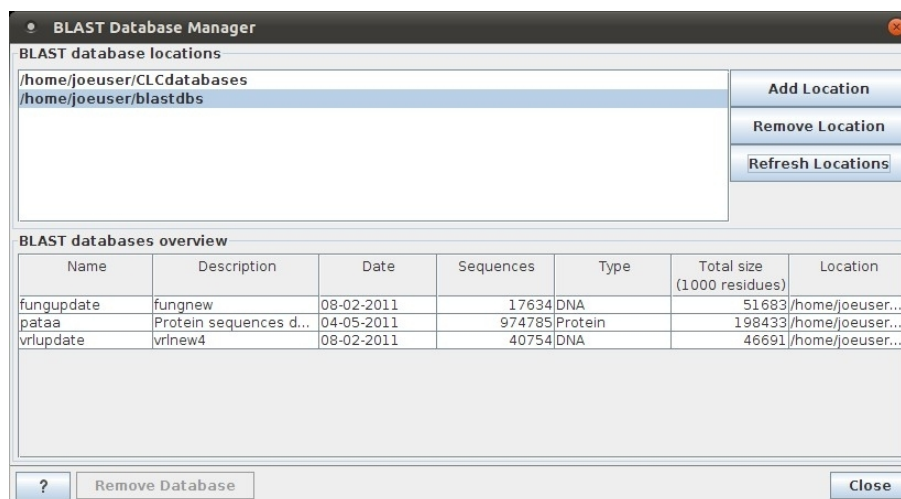

Figure 13.14: Overview of available BLAST databases.

At the top of the dialog, there is a list of the **BLAST database locations**. These locations are folders where the Workbench will look for valid BLAST databases. These can either be created from within the Workbench using the **Create BLAST Database tool**, see section 13.3.3, or they can be pre-formatted BLAST databases.

The list of locations can be modified using the **Add Location** and **Remove Location** buttons. Once the Workbench has scanned the locations, it will keep a cache of the databases (in order

to improve performance). If you have added new databases that are not listed, you can press **Refresh Locations** to clear the cache and search the database locations again.

By default a BLAST database location will be added under your home area in a folder called CLCdatabases. This folder is scanned recursively, through all subfolders, to look for valid databases. All other folder locations are scanned only at the top level.

Below the list of locations, all the BLAST databases are listed with the following information:

- **Name.** The name of the BLAST database.
- **Description.** Detailed description of the contents of the database.
- **Date.** The date the database was created.
- **Sequences.** The number of sequences in the database.
- **Type.** The type can be either nucleotide (DNA) or protein.
- **Total size (1000 residues).** The number of residues in the database, either bases or amino acid.
- **Location.** The location of the database.

Below the list of BLAST databases, there is a button to **Remove Database**. This option will delete the database files belonging to the database selected.

13.4.1 Migrating from a previous version of the Workbench

In versions released before 2011, the BLAST database management was very different from this. In order to migrate from the older versions, please add the folders of the old BLAST databases as locations in the BLAST database manager (see section 13.4). The old representations of the BLAST databases in the **Navigation Area** can be deleted.

If you have saved the BLAST databases in the default folder, they will automatically appear because the default database location used in *CLC Main Workbench 6.8* is the same as the default folder specified for saving BLAST databases in the old version.

13.5 Bioinformatics explained: BLAST

BLAST (Basic Local Alignment Search Tool) has become the *defacto* standard in search and alignment tools [Altschul et al., 1990]. The BLAST algorithm is still actively being developed and is one of the most cited papers ever written in this field of biology. Many researchers use BLAST as an initial screening of their sequence data from the laboratory and to get an idea of what they are working on. BLAST is far from being basic as the name indicates; it is a highly advanced algorithm which has become very popular due to availability, speed, and accuracy. In short, a BLAST search identifies homologous sequences by searching one or more databases usually hosted by NCBI (<http://www.ncbi.nlm.nih.gov/>), on the query sequence of interest [McGinnis and Madden, 2004].

BLAST is an open source program and anyone can download and change the program code. This has also given rise to a number of BLAST derivatives; WU-BLAST is probably the most commonly used [Altschul and Gish, 1996].

BLAST is highly scalable and comes in a number of different computer platform configurations which makes usage on both small desktop computers and large computer clusters possible.

13.5.1 Examples of BLAST usage

BLAST can be used for a lot of different purposes. A few of them are mentioned below.

- **Looking for species.** If you are sequencing DNA from unknown species, BLAST may help identify the correct species or homologous species.
- **Looking for domains.** If you BLAST a protein sequence (or a translated nucleotide sequence) BLAST will look for known domains in the query sequence.
- **Looking at phylogeny.** You can use the BLAST web pages to generate a phylogenetic tree of the BLAST result.
- **Mapping DNA to a known chromosome.** If you are sequencing a gene from a known species but have no idea of the chromosome location, BLAST can help you. BLAST will show you the position of the query sequence in relation to the hit sequences.
- **Annotations.** BLAST can also be used to map annotations from one organism to another or look for common genes in two related species.

13.5.2 Searching for homology

Most research projects involving sequencing of either DNA or protein have a requirement for obtaining biological information of the newly sequenced and maybe unknown sequence. If the researchers have no prior information of the sequence and biological content, valuable information can often be obtained using BLAST. The BLAST algorithm will search for homologous sequences in predefined and annotated databases of the users choice.

In an easy and fast way the researcher can gain knowledge of gene or protein function and find evolutionary relations between the newly sequenced DNA and well established data.

After the BLAST search the user will receive a report specifying found homologous sequences and their local alignments to the query sequence.

13.5.3 How does BLAST work?

BLAST identifies homologous sequences using a heuristic method which initially finds short matches between two sequences; thus, the method does not take the entire sequence space into account. After initial match, BLAST attempts to start local alignments from these initial matches. This also means that BLAST does not guarantee the optimal alignment, thus some sequence hits may be missed. In order to find optimal alignments, the Smith-Waterman algorithm should be used (see below). In the following, the BLAST algorithm is described in more detail.

Seeding

When finding a match between a query sequence and a hit sequence, the starting point is the words that the two sequences have in common. A word is simply defined as a number of letters.

For blastp the default word size is 3 $W=3$. If a query sequence has a QWRTG, the searched words are QWR, WRT, RTG. See figure 13.15 for an illustration of words in a protein sequence.

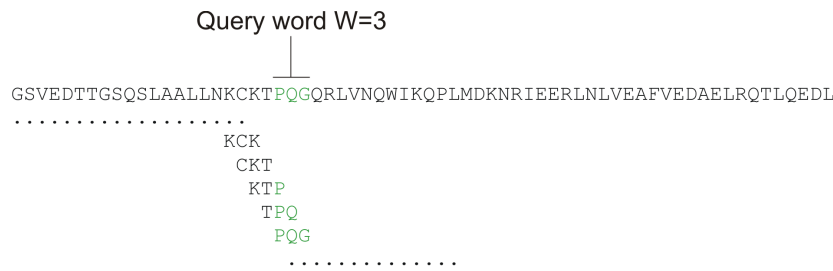

Figure 13.15: Generation of exact BLAST words with a word size of $W=3$.

During the initial BLAST seeding, the algorithm finds all common words between the query sequence and the hit sequence(s). Only regions with a word hit will be used to build on an alignment.

BLAST will start out by making words for the entire query sequence (see figure 13.15). For each word in the query sequence, a compilation of neighborhood words, which exceed the threshold of T , is also generated.

A neighborhood word is a word obtaining a score of at least T when comparing, using a selected scoring matrix (see figure 13.16). The default scoring matrix for blastp is BLOSUM62 (for explanation of scoring matrices, see www.clcbio.com/be). The compilation of exact words and neighborhood words is then used to match against the database sequences.

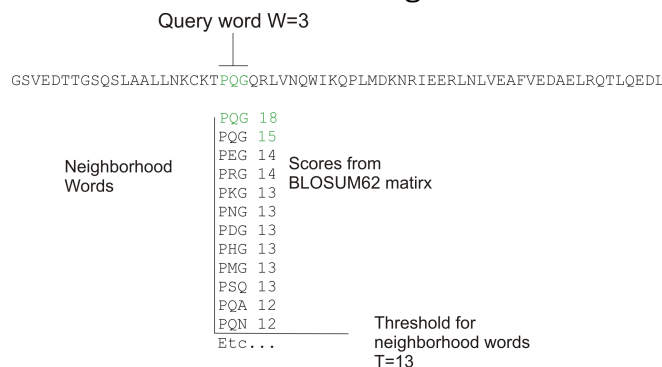

Figure 13.16: Neighborhood BLAST words based on the BLOSUM62 matrix. Only words where the threshold T exceeds 13 are included in the initial seeding.

After initial finding of words (seeding), the BLAST algorithm will extend the (only 3 residues long) alignment in both directions (see figure 13.17). Each time the alignment is extended, an alignment score is increases/decreased. When the alignment score drops below a predefined threshold, the extension of the alignment stops. This ensures that the alignment is not extended to regions where only very poor alignment between the query and hit sequence is possible. If the obtained alignment receives a score above a certain threshold, it will be included in the final BLAST result.

By tweaking the word size W and the neighborhood word threshold T , it is possible to limit the search space. E.g. by increasing T , the number of neighboring words will drop and thus limit the search space as shown in figure 13.18.

This will increase the speed of BLAST significantly but may result in loss of sensitivity. Increasing the word size W will also increase the speed but again with a loss of sensitivity.

```

Figure 13.17: Blast aligning in both directions. The initial word match is marked green.

Figure 13.18: Each dot represents a word match. Increasing the threshold of T limits the search space significantly.

13.5.4 Which BLAST program should I use?

Depending on the nature of the sequence it is possible to use different BLAST programs for the database search. There are five versions of the BLAST program, blastn, blastp, blastx, tblastn, tblastx:

Option	Query Type	DB Type	Comparison	Note
blastn	Nucleotide	Nucleotide	Nucleotide-Nucleotide	
blastp	Protein	Protein	Protein-Protein	
tblastn	Protein	Nucleotide	Protein-Protein	The database is translated into protein
blastx	Nucleotide	Protein	Protein-Protein	The queries are translated into protein
tblastx	Nucleotide	Nucleotide	Protein-Protein	The queries and database are translated into protein

The most commonly used method is to BLAST a nucleotide sequence against a nucleotide database (blastn) or a protein sequence against a protein database (blastp). But often another BLAST program will produce more interesting hits. E.g. if a nucleotide sequence is translated

before the search, it is more likely to find better and more accurate hits than just a `blastn` search. One of the reasons for this is that protein sequences are evolutionarily more conserved than nucleotide sequences. Another good reason for translating the query sequence before the search is that you get protein hits which are likely to be annotated. Thus you can directly see the protein function of the sequenced gene.

13.5.5 Which BLAST options should I change?

The NCBI BLAST web pages and the BLAST command line tool offer a number of different options which can be changed in order to obtain the best possible result. Changing these parameters can have a great impact on the search result. It is not the scope of this document to comment on all of the options available but merely the options which can be changed with a direct impact on the search result.

The E-value

The *expect value* (E-value) can be changed in order to limit the number of hits to the most significant ones. The lower the E-value, the better the hit. The E-value is dependent on the length of the query sequence and the size of the database. For example, an alignment obtaining an E-value of 0.05 means that there is a 5 in 100 chance of occurring by chance alone.

E-values are very dependent on the query sequence length and the database size. Short identical sequence may have a high E-value and may be regarded as "false positive" hits. This is often seen if one searches for short primer regions, small domain regions etc. The default threshold for the E-value on the BLAST web page is 10. Increasing this value will most likely generate more hits. Below are some rules of thumb which can be used as a guide but should be considered with common sense.

- **E-value < 10e-100** Identical sequences. You will get long alignments across the entire query and hit sequence.
- **10e-100 < E-value < 10e-50** Almost identical sequences. A long stretch of the query protein is matched to the database.
- **10e-50 < E-value < 10e-10** Closely related sequences, could be a domain match or similar.
- **10e-10 < E-value < 1** Could be a true homologue but it is a gray area.
- **E-value > 1** Proteins are most likely not related
- **E-value > 10** Hits are most likely junk unless the query sequence is very short.

Gap costs

For `blastp` it is possible to specify gap cost for the chosen substitution matrix. There is only a limited number of options for these parameters. The *open gap cost* is the price of introducing gaps in the alignment, and *extension gap cost* is the price of every extension past the initial opening gap. Increasing the gap costs will result in alignments with fewer gaps.

Filters

It is possible to set different filter options before running the BLAST search. Low-complexity regions have a very simple composition compared to the rest of the sequence and may result in problems during the BLAST search [Wootton and Federhen, 1993]. A low complexity region of a protein can for example look like this 'fftflllss', which in this case is a region as part of a signal peptide. In the output of the BLAST search, low-complexity regions will be marked in lowercase gray characters (default setting). The low complexity region cannot be thought of as a significant match; thus, disabling the low complexity filter is likely to generate more hits to sequences which are not truly related.

Word size

Change of the word size has a great impact on the seeded sequence space as described above. But one can change the word size to find sequence matches which would otherwise not be found using the default parameters. For instance the word size can be decreased when searching for primers or short nucleotides. For `blastn` a suitable setting would be to decrease the default word size of 11 to 7, increase the E-value significantly (1000) and turn off the complexity filtering.

For `blastp` a similar approach can be used. Decrease the word size to 2, increase the E-value and use a more stringent substitution matrix, e.g. a PAM30 matrix.

Fortunately, the optimal search options for finding short, nearly exact matches can already be found on the BLAST web pages <http://www.ncbi.nlm.nih.gov/BLAST/>.

Substitution matrix

For protein BLAST searches, a default substitution matrix is provided. If you are looking at distantly related proteins, you should either choose a high-numbered PAM matrix or a low-numbered BLOSUM matrix. See *Bioinformatics Explained* on scoring matrices on <http://www.clcbio.com/be/>. The default scoring matrix for `blastp` is BLOSUM62.

13.5.6 Explanation of the BLAST output

The BLAST output comes in different flavors. On the NCBI web page the default output is html, and the following description will use the html output as example. Ordinary text and xml output for easy computational parsing is also available.

The default layout of the NCBI BLAST result is a graphical representation of the hits found, a table of sequence identifiers of the hits together with scoring information, and alignments of the query sequence and the hits.

The graphical output (shown in figure 13.19) gives a quick overview of the query sequence and the resulting hit sequences. The hits are colored according to the obtained alignment scores.

The table view (shown in figure 13.20) provides more detailed information on each hit and furthermore acts as a hyperlink to the corresponding sequence in GenBank.

In the alignment view one can manually inspect the individual alignments generated by the BLAST algorithm. This is particularly useful for detailed inspection of the sequence hit found (subject) and the corresponding alignment. In the alignment view, all scores are described for each alignment,

Figure 13.19: BLAST graphical view. A simple graphical overview of the hits found aligned to the query sequence. The alignments are color coded ranging from black to red as indicated in the color label at the top.

Sequences producing significant alignments:

Figure 13.21: Alignment view of BLAST results. Individual alignments are represented together with BLAST scores and more.

13.5.7 I want to BLAST against my own sequence database, is this possible?

It is possible to download the entire BLAST program package and use it on your own computer, institution computer cluster or similar. This is preferred if you want to search in proprietary sequences or sequences unavailable in the public databases stored at NCBI. The downloadable BLAST package can either be installed as a web-based tool or as a command line tool. It is available for a wide range of different operating systems.

The BLAST package can be downloaded free of charge from the following location <http://www.ncbi.nlm.nih.gov/BLAST/download.shtml>

Pre-formatted databases are available from a dedicated BLAST ftp site <ftp://ftp.ncbi.nlm.nih.gov/blast/db/>. Moreover, it is possible to download programs/scripts from the same site enabling automatic download of changed BLAST databases. Thus it is possible to schedule a nightly update of changed databases and have the updated BLAST database stored locally or on a shared network drive at all times. Most BLAST databases on the NCBI site are updated on a daily basis to include all recent sequence submissions to GenBank.

A few commercial software packages are available for searching your own data. The advantage of using a commercial program is obvious when BLAST is integrated with the existing tools of these programs. Furthermore, they let you perform BLAST searches and retain annotations on the query sequence (see figure 13.22). It is also much easier to batch download a selection of hit sequences for further inspection.

Figure 13.22: Snippet of alignment view of BLAST results from CLC Main Workbench. Individual alignments are represented directly in a graphical view. The top sequence is the query sequence and is shown with a selection of annotations.

13.5.8 What you cannot get out of BLAST

Don't expect BLAST to produce the best available alignment. BLAST is a heuristic method which does not guarantee the best results, and therefore you cannot rely on BLAST if you wish to find *all* the hits in the database.

Instead, use the Smith-Waterman algorithm for obtaining the best possible local alignments [Smith and Waterman, 1981].

BLAST only makes local alignments. This means that a great but short hit in another sequence may not at all be related to the query sequence even though the sequences align well in a small region. It may be a domain or similar.

It is always a good idea to be cautious of the material in the database. For instance, the sequences may be wrongly annotated; hypothetical proteins are often simple translations of a found ORF on a sequenced nucleotide sequence and may not represent a true protein.

Don't expect to see the best result using the default settings. As described above, the settings should be adjusted according to the what kind of query sequence is used, and what kind of results you want. It is a good idea to perform the same BLAST search with different settings to get an idea of how they work. There is not a final answer on how to adjust the settings for your particular sequence.

14.1 Importing structure files	262
14.2 Viewing structure files	263
14.2.1 Moving and rotating	263
14.3 Selections and display of the 3D structure	264
14.3.1 Coloring of the 3D structure	264
14.3.2 Hierarchical view - changing how selections of the structure are displayed	265
14.4 3D Output	269

In order to understand protein function it is often valuable to see the actual three dimensional structure of the protein. This is of course only possible if the structure of the protein has been resolved and published. *CLC Main Workbench* has an integrated viewer of structure files. Structure files are usually deposited at the Protein DataBank (PDB) www.rcsb.org, where protein structure files can be searched and downloaded.

14.1 Importing structure files

In order to view the three dimensional structure files there are different ways to import these. The supported file formats are PDB and mmCIF which both can be downloaded from the Protein DataBank (<http://www.rcsb.org>) and imported through the import menu (see section 7.1).

Another way to import structure files is if a structure file is found through a direct search at the GenBank structure database (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=Structure>). Read more about search for structures in section 12.3.

It is also possible to make a BLAST search against the PDB database. In the latter case, structure files can be directly downloaded to the navigation area by clicking the **Open structure** button below all the BLAST hits. Downloading structure files from a conducted BLAST search is only possible if the results are shown in a BLAST table. (See figure 14.1). How to conduct a BLAST search can be seen in section 13.1.1.

Download and Open Download and Save Open at NCBI Open Structure

Figure 14.1: It is possible to open a structure file directly from the output of a conducted BLAST search by clicking the Open Structure button.

14.2 Viewing structure files

An example of a 3D structure is shown in figure 14.2.

Figure 14.2: 3D view. Structure files can be opened, viewed and edited in several ways.

Structures can be rotated and moved using the mouse and keyboard. **Pan mode** (☞) must be enabled in order to rotate and move the sequence.

Note! It is only possible to view one structure file at a time, in order to limit the amount of memory used.

14.2.1 Moving and rotating

Structure files are simply rotated by holding down the left mouse button while moving the mouse. This will rotate the structure in the direction the mouse is moved. The structures can be freely rotated in all directions.

Holding down the Ctrl on Windows or ⌘ on Mac key on the keyboard while dragging the mouse

moves the structure in the direction the mouse is moved. This is particularly useful if the view is zoomed to cover only a small region of the protein structure.

Zoom in () and zoom out () on the structure is done by selecting the appropriate zoom tool in the toolbar and clicking with the mouse on the view area. Alternatively, click and hold the left mouse button while using either zoom tool and move the mouse up or down to zoom out or in respectively. The view can be restored to display the entire structure by clicking the **Fit width** () button on the toolbar (read more about zooming in section 3.2).

- **Rotate mode**

The structure is rotated when the "Pan mode" () is selected in the toolbar. If the "pan mode" is not enabled on the first view of a structure a warning is shown.

- **Zoom mode**

Use the zoom buttons on the toolbar to enable zoom mode. A single click with the mouse will zoom slightly on the structure. Moreover, it is possible to zoom in and out on the structure by keeping the left mouse button pressed while moving the mouse up and down.

- **Move mode**

It is possible to move the structure from side to side if the Ctrl key on Windows and ⌘ key on Mac is pressed while dragging with the mouse.

14.3 Selections and display of the 3D structure

The view of the structure can be changed in several ways. All graphical changes are carried out through the **Side Panel**. At the top, you can change the default coloring (**Default colors** and **Settings**), and at the bottom you can change the representation of specific parts of the structure in order to high-light e.g. an active site.

14.3.1 Coloring of the 3D structure

The default colors apply if nothing else has been specified in the **Hierarchical view** below (see section 14.3.2):

- **Atom type.** Colors the atoms individually.
 - **Carbon:** Light grey
 - **Oxygen:** Red
 - **Hydrogen:** White
 - **Nitrogen:** Light blue
 - **Sulphur:** Yellow
 - **Chlorine, Boron:** Green
 - **Phosphorus, Iron, Barium:** Orange
 - **Sodium:** Blue
 - **Magnesium:** Forest green
 - **Zn, Cu, Ni, Br:** Brown
 - **Ca, Mn, Al, Ti, Cr, Ag:** Dark grey

- **F, Si, Au:** Goldenrod
 - **Iodine:** Purple
 - **Lithium:** firebrick
 - **Helium:** Pink
 - **Other:** Deep pink
- **Entities.** This will color protein subunits and additional structures individually. Using the view table, the user may select which colors are used to color subunits.
 - **Rainbow.** This color mode will color the structure with rainbow colors along the sequence.
 - **Residue hydrophobicity.** Colors the residues according to hydrophobicity.

In the **Settings** group, you can specify the background color to use. Default is black.

14.3.2 Hierarchical view - changing how selections of the structure are displayed

In the bottom of the **Side Panel**, you see the hierarchical view of the 3D structure (see an example in figure 14.3).

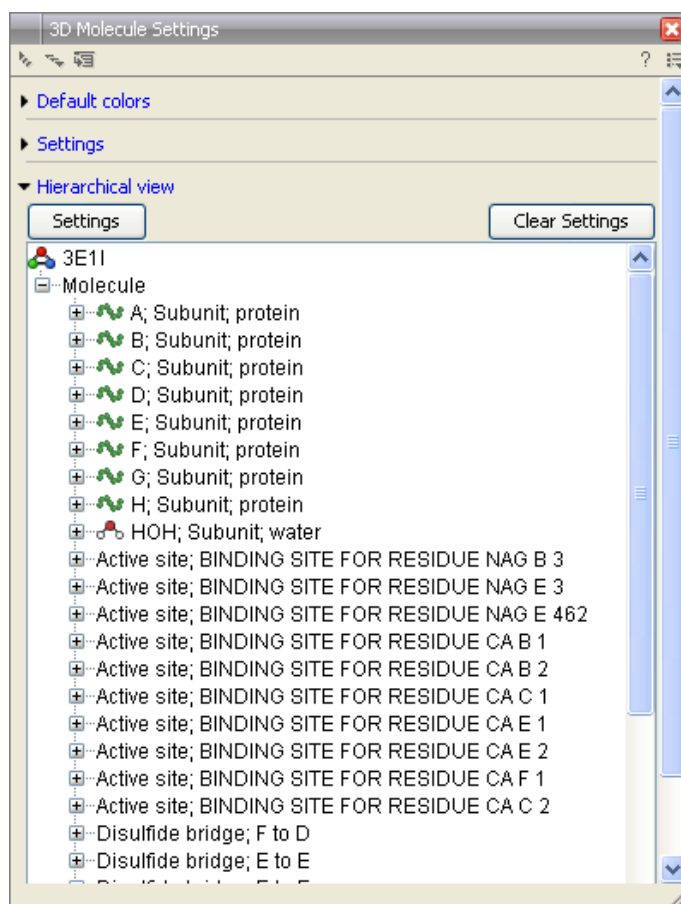

Figure 14.3: Hierarchy view in the Side Panel.

The hierarchical view shows the structure in a detailed manner. Individual structure subunits, residues, active sites, disulfide bridges or even down to the atom level can be selected individually and colored accordingly.

You can show additional information from the hierarchical view by holding your mouse still for one second (see an example in figure 14.4).

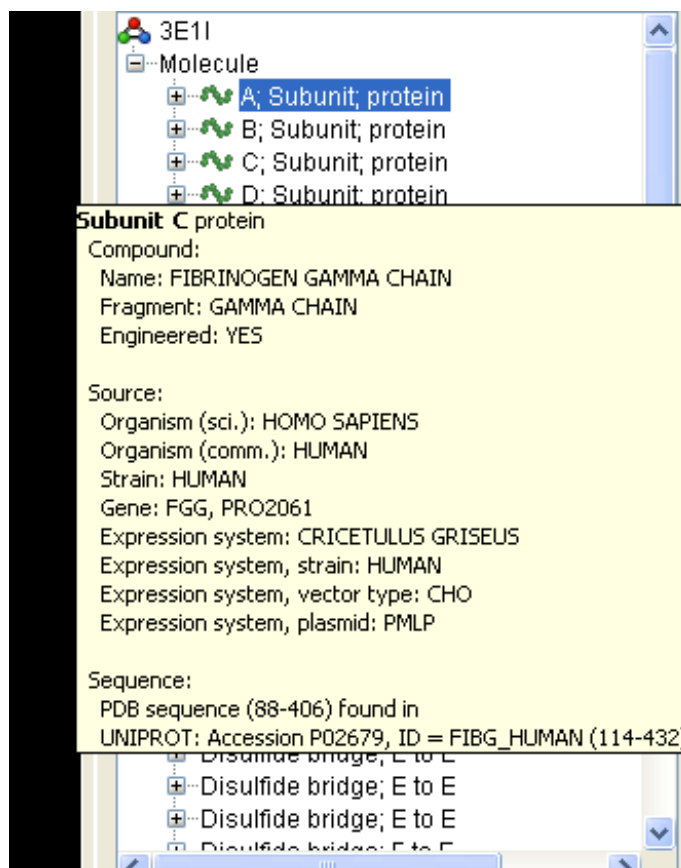

Figure 14.4: Details shown by holding the mouse cursor on a subunit.

For each item in the hierarchy view, you can apply special view settings. Simply click an item in the hierarchy view and click the **Settings** button above. This will display the settings dialog as shown in figure 14.5.

Figure 14.5: Customize appearance.

There are four tabs at the top. You can specify settings for each tab and then click **OK** to apply and close the dialog. You can also click **Apply** which will keep the settings dialog visible. You will then be able to select another item in the hierarchical view and apply settings for this also.

Atoms

The **Atoms** tab is shown in figure 14.5. At the top, you can choose to show atoms, and below you can specify their appearance:

- **Color.** Clicking the color box allows you to select a color.
- **Opacity.** Determines the level of opacity.
- **Atom size.** The size of the atoms measured by vdW radius.

Bonds

The **Bonds** tab is shown in figure 14.6.

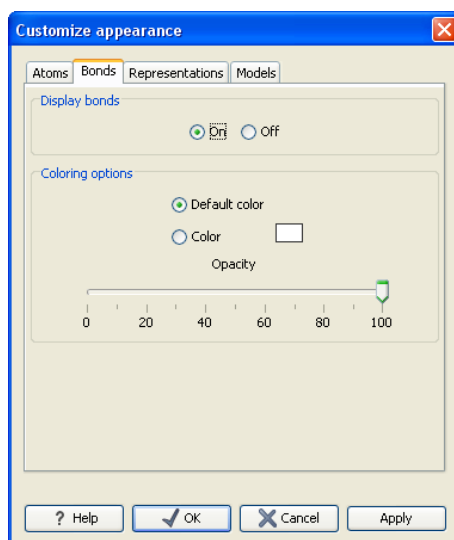

Figure 14.6: *Customize appearance for bonds.*

At the top, you can choose to show bonds, and below you can specify their appearance:

- **Color.** Clicking the color box allows you to select a color.
- **Opacity.** Determines the level of opacity.

Representations

The **Representations** tab is shown in figure 14.7.

At the top, you can choose to between four display models:

- **Secondary structure.**

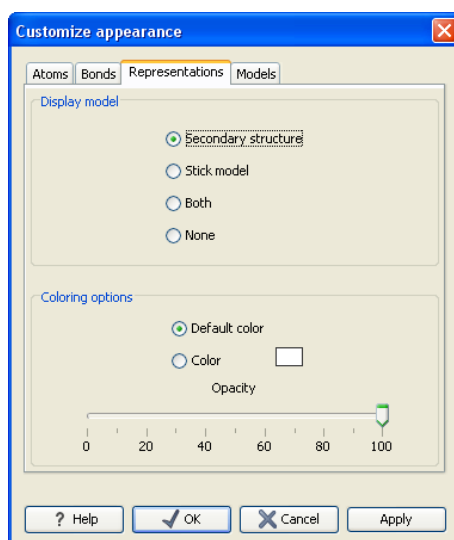

Figure 14.7: *Customize appearance for representations.*

- **Stick model.**
- **Both.** Displaying both secondary structure and stick model.
- **None.** Will not display representations.
- **Color.** Clicking the color box allows you to select a color.
- **Opacity.** Determines the level of opacity.

Models

The **Models** tab is shown in figure 14.8. At the top, you can choose to between three display

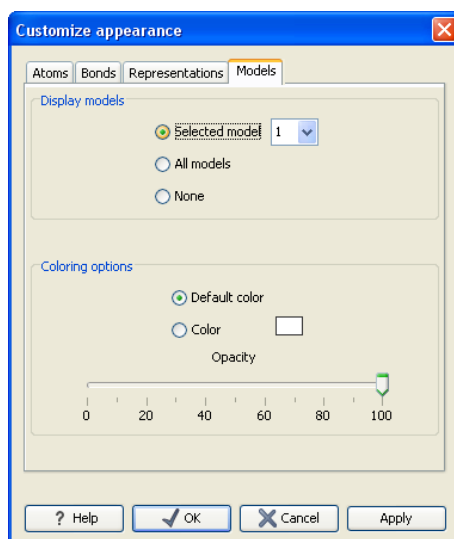

Figure 14.8: *Customize appearance for models.*

modes. This functionality is only applicable to NMR structures which have multiple resolved structures, for X-ray structures only one structure is available:

- **Selected model.**
- **All models.**
- **None.** Will not display models.
- **Color.** Clicking the color box allows you to select a color.
- **Opacity.** Determines the level of opacity.

14.4 3D Output

The output of the 3D view is rendered on the screen in real time and changes to the preferences are visible immediately. From *CLC Main Workbench* you can export the visible part of the 3D view to different graphic formats, by pressing the **Graphics** button  on the **Menu bar**. This will allow you to export in the following formats:

Format	Suffix	Type
Portable Network Graphics	.png	bitmap
JPEG	.jpg	bitmap
Tagged Image File	.tif	bitmap
PostScript	.ps	vector graphics
Encapsulated PostScript	.eps	vector graphics
Portable Document Format	.pdf	vector graphics
Scalable Vector Graphics	.svg	vector graphics

Printing is not fully implemented with the 3D editor. Should you wish to print a 3D view, this can be done by either exporting to a graphics format and printing that or use the scheme below.

Windows:

- Adjust your 3D view in *CLC Main Workbench*
- Press **Print Screen** on your keyboard (or **Alt + Print Screen**)
- Paste the result into an 'image editor' e.g. Paint or GIMP <http://www.gimp.org/>
- Crop (edit the screen shot)
- Save in your preferred file format and/or print

Mac:

- Set up your 3D view
- Press **⌘ + shift + 3** (or **⌘ + shift + 4**) (to take screen shot)
- Open the saved file (.pdf or .png) in a 'image editor' e.g. GIMP <http://www.gimp.org/>
- Crop (edit the screen shot)
- Save in your preferred file format and/or print

Linux:

- Set up your 3D view
- e.g. use GIMP to take the screen shot <http://www.gimp.org/>
- Crop (edit the screen shot)
- Save in your preferred file format and/or print

CLC Main Workbench offers different kinds of sequence analyses, which apply to both protein and DNA. The analyses are described in this chapter.

15.1 Shuffle sequence

In some cases, it is beneficial to shuffle a sequence. This is an option in the **Toolbox** menu under **General Sequence Analyses**. It is normally used for statistical analyses, e.g. when comparing an alignment score with the distribution of scores of shuffled sequences.

Shuffling a sequence removes all annotations that relate to the residues.

select sequence | Toolbox in the Menu Bar | General Sequence Analysis (🔧) | Shuffle Sequence (🔀)

or **right-click a sequence** | **Toolbox** | **General Sequence Analysis** (🛠️) | **Shuffle Sequence** (🔀)

This opens the dialog displayed in figure 15.1:

Figure 15.1: Choosing sequence for shuffling.

If a sequence was selected before choosing the Toolbox action, this sequence is now listed in the **Selected Elements** window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements.

Click **Next** to determine how the shuffling should be performed.

In this step, shown in figure 15.2: For nucleotides, the following parameters can be set:

Figure 15.2: Parameters for shuffling.

- **Mononucleotide shuffling.** Shuffle method generating a sequence of the exact same mononucleotide frequency
- **Dinucleotide shuffling.** Shuffle method generating a sequence of the exact same dinucleotide frequency
- **Mononucleotide sampling from zero order Markov chain.** Resampling method generating a sequence of the same expected mononucleotide frequency.

- **Dinucleotide sampling from first order Markov chain.** Resampling method generating a sequence of the same expected dinucleotide frequency.

For proteins, the following parameters can be set:

- **Single amino acid shuffling.** Shuffle method generating a sequence of the exact same amino acid frequency.
- **Single amino acid sampling from zero order Markov chain.** Resampling method generating a sequence of the same expected single amino acid frequency.
- **Dipeptide shuffling.** Shuffle method generating a sequence of the exact same dipeptide frequency.
- **Dipeptide sampling from first order Markov chain.** Resampling method generating a sequence of the same expected dipeptide frequency.

For further details of these algorithms, see [Clote et al., 2005]. In addition to the shuffle method, you can specify the number of randomized sequences to output.

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

This will open a new view in the **View Area** displaying the shuffled sequence. The new sequence is not saved automatically. To save the sequence, drag it into the **Navigation Area** or press ctrl + S (⌘ + S on Mac) to activate a save dialog.

15.2 Dot plots

Dot plots provide a powerful visual comparison of two sequences. Dot plots can also be used to compare regions of similarity within a sequence. This chapter first describes how to create and second how to adjust the view of the plot.

15.2.1 Create dot plots

A dot plot is a simple, yet intuitive way of comparing two sequences, either DNA or protein, and is probably the oldest way of comparing two sequences [Maizel and Lenk, 1981]. A dot plot is a 2 dimensional matrix where each axis of the plot represents one sequence. By sliding a fixed size window over the sequences and making a sequence match by a dot in the matrix, a diagonal line will emerge if two identical (or very homologous) sequences are plotted against each other. Dot plots can also be used to visually inspect sequences for direct or inverted repeats or regions with low sequence complexity. Various smoothing algorithms can be applied to the dot plot calculation to avoid noisy background of the plot. Moreover, can various substitution matrices be applied in order to take the evolutionary distance of the two sequences into account.

To create a dot plot:

Toolbox | General Sequence Analysis (📁) | Create Dot Plot (🔗)

or **Select one or two sequences in the Navigation Area | Toolbox in the Menu Bar | General Sequence Analysis (📁) | Create Dot Plot (🔗)**

or **Select one or two sequences in the Navigation Area | right-click in the Navigation Area | Toolbox | General Sequence Analysis (🔧) | Create Dot Plot (📊)**

This opens the dialog shown in figure 15.3.

Figure 15.3: Selecting sequences for the dot plot.

If a sequence was selected before choosing the **Toolbox** action, this sequence is now listed in the **Selected Elements** window of the dialog. Use the arrows to add or remove elements from the selected elements. Click **Next** to adjust dot plot parameters. Clicking **Next** opens the dialog shown in figure 15.4.

Notice! Calculating dot plots take up a considerable amount of memory in the computer. Therefore, you see a warning if the sum of the number of nucleotides/amino acids in the sequences is higher than 8000. If you insist on calculating a dot plot with more residues the Workbench may shut down, allowing you to save your work first. However, this depends on your computer's memory configuration.

Adjust dot plot parameters

There are two parameters for calculating the dot plot:

- **Distance correction (only valid for protein sequences)** In order to treat evolutionary transitions of amino acids, a distance correction measure can be used when calculating the dot plot. These distance correction matrices (substitution matrices) take into account the likeliness of one amino acid changing to another.
- **Window size** A residue by residue comparison (window size = 1) would undoubtedly result in a very noisy background due to a lot of similarities between the two sequences of interest. For DNA sequences the background noise will be even more dominant as a match between only four nucleotide is very likely to happen. Moreover, a residue by residue comparison (window size = 1) can be very time consuming and computationally demanding. Increasing the window size will make the dot plot more 'smooth'.

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

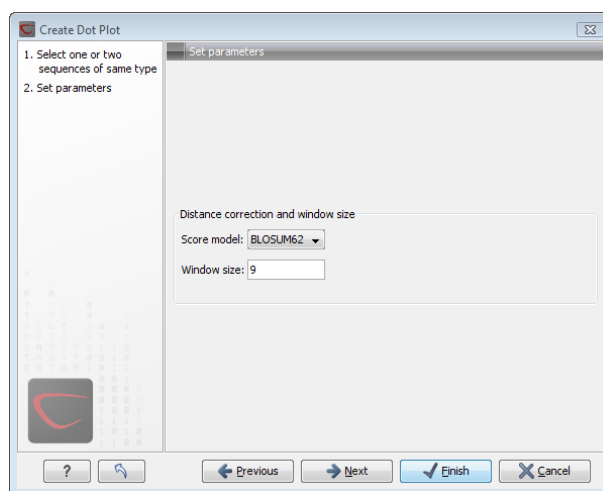

Figure 15.4: Setting the dot plot parameters.

15.2.2 View dot plots

A view of a dot plot can be seen in figure 15.5. You can select **Zoom in** (🔍) in the Toolbar and click the dot plot to zoom in to see the details of particular areas.

Figure 15.5: A view is opened showing the dot plot.

The **Side Panel** to the right let you specify the dot plot preferences. The gradient color box can be adjusted to get the appropriate result by dragging the small pointers at the top of the box. Moving the slider from the right to the left lowers the thresholds which can be directly seen in the dot plot, where more diagonal lines will emerge. You can also choose another color gradient by clicking on the gradient box and choose from the list.

Adjusting the sliders above the gradient box is also practical, when producing an output for printing. (Too much background color might not be desirable). By crossing one slider over the other (the two sliders change side) the colors are inverted, allowing for a white background. (If you choose a color gradient, which includes white). See figure 15.5.

Figure 15.6: Dot plot with inverted colors, practical for printing.

15.2.3 Bioinformatics explained: Dot plots

Realization of dot plots

Dot plots are two-dimensional plots where the x-axis and y-axis each represents a sequence and the plot itself shows a comparison of these two sequences by a calculated score for each position of the sequence. If a window of fixed size on one sequence (one axis) match to the other sequence a dot is drawn at the plot. Dot plots are one of the oldest methods for comparing two sequences [Maizel and Lenk, 1981].

The scores that are drawn on the plot are affected by several issues.

- Scoring matrix for distance correction.
Scoring matrices (BLOSUM and PAM) contain substitution scores for every combination of two amino acids. Thus, these matrices can only be used for dot plots of protein sequences.
- Window size
The single residue comparison (bit by bit comparison(window size = 1)) in dot plots will undoubtedly result in a noisy background of the plot. You can imagine that there are many successes in the comparison if you only have four possible residues like in nucleotide sequences. Therefore you can set a window size which is smoothing the dot plot. Instead of comparing single residues it compares subsequences of length set as window size. The score is now calculated with respect to aligning the subsequences.
- Threshold
The dot plot shows the calculated scores with colored threshold. Hence you can better recognize the most important similarities.

Examples and interpretations of dot plots

Contrary to simple sequence alignments dot plots can be a very useful tool for spotting various evolutionary events which may have happened to the sequences of interest.

Below is shown some examples of dot plots where sequence insertions, low complexity regions, inverted repeats etc. can be identified visually.

Similar sequences

The most simple example of a dot plot is obtained by plotting two homologous sequences of interest. If very similar or identical sequences are plotted against each other a diagonal line will occur.

The dot plot in figure 15.7 shows two related sequences of the Influenza A virus nucleoproteins infecting ducks and chickens. Accession numbers from the two sequences are: DQ232610 and DQ023146. Both sequences can be retrieved directly from <http://www.ncbi.nlm.nih.gov/gquery/gquery.fcgi>.

Figure 15.7: Dot plot of DQ232610 vs. DQ023146 (Influenza A virus nucleoproteins) showing and overall similarity

Repeated regions

Sequence repeats can also be identified using dot plots. A repeat region will typically show up as lines parallel to the diagonal line.

If the dot plot shows more than one diagonal in the same region of a sequence, the regions depending to the other sequence are repeated. In figure 15.9 you can see a sequence with repeats.

Figure 15.8: *Direct and inverted repeats shown on an amino acid sequence generated for demonstration purposes.*

Figure 15.9: *The dot plot of a sequence showing repeated elements. See also figure 15.8.*

Frame shifts

Frame shifts in a nucleotide sequence can occur due to insertions, deletions or mutations. Such frame shifts can be visualized in a dot plot as seen in figure 15.10. In this figure, three frame shifts for the sequence on the y-axis are found.

1. Deletion of nucleotides
2. Insertion of nucleotides
3. Mutation (out of frame)

Sequence inversions

Figure 15.10: This dot plot show various frame shifts in the sequence. See text for details.

In dot plots you can see an inversion of sequence as contrary diagonal to the diagonal showing similarity. In figure 15.11 you can see a dot plot (window length is 3) with an inversion.

Low-complexity regions

Low-complexity regions in sequences can be found as regions around the diagonal all obtaining a high score. Low complexity regions are calculated from the redundancy of amino acids within a limited region [Wootton and Federhen, 1993]. These are most often seen as short regions of only a few different amino acids. In the middle of figure 15.12 is a square shows the low-complexity region of this sequence.

15.2.4 Bioinformatics explained: Scoring matrices

Biological sequences have evolved throughout time and evolution has shown that not all changes to a biological sequence is equally likely to happen. Certain amino acid substitutions (change of one amino acid to another) happen often, whereas other substitutions are very rare. For instance, tryptophan (W) which is a relatively rare amino acid, will only – on very rare occasions – mutate into a leucine (L).

Based on evolution of proteins it became apparent that these changes or substitutions of amino acids can be modeled by a scoring matrix also referred to as a substitution matrix. See an example of a scoring matrix in table 15.1. This matrix lists the substitution scores of every single amino acid. A score for an aligned amino acid pair is found at the intersection of the corresponding column and row. For example, the substitution score from an arginine (R) to a lysine (K) is 2. The diagonal show scores for amino acids which have not changed. Most substitutions changes have a negative score. Only rounded numbers are found in this matrix.

The two most used matrices are the BLOSUM [Henikoff and Henikoff, 1992] and PAM [Dayhoff and Schwartz, 1978].

Figure 15.12: The dot plot showing a low-complexity region in the sequence. The sequence is artificial and low complexity regions does not always show as a square.

Different scoring matrices

PAM

The first PAM matrix (Point Accepted Mutation) was published in 1978 by Dayhoff et al. The PAM matrix was build through a global alignment of related sequences all having sequence similarity above 85% [Dayhoff and Schwartz, 1978]. A PAM matrix shows the probability that any given amino acid will mutate into another in a given time interval. As an example, PAM1 gives that one amino acid out of a 100 will mutate in a given time interval. In the other end of the scale, a PAM256 matrix, gives the probability of 256 mutations in a 100 amino acids (see figure 15.13).

There are some limitation to the PAM matrices which makes the BLOSUM matrices somewhat more attractive. The dataset on which the initial PAM matrices were build is very old by now, and the PAM matrices assume that all amino acids mutate at the same rate - this is not a correct assumption.

BLOSUM

In 1992, 14 years after the PAM matrices were published, the BLOSUM matrices (BLOcks Substitution Matrix) were developed and published [Henikoff and Henikoff, 1992].

Henikoff et al. wanted to model more divergent proteins, thus they used locally aligned sequences where none of the aligned sequences share less than 62% identity. This resulted

	A	R	N	D	C	Q	E	G	H	I	L	K	M	F	P	S	T	W	Y	V

Table 15.1: **The BLOSUM62 matrix.** A tabular view of the BLOSUM62 matrix containing all possible substitution scores [Henikoff and Henikoff, 1992].

in a scoring matrix called BLOSUM62. In contrast to the PAM matrices the BLOSUM matrices are calculated from alignments without gaps emerging from the BLOCKS database <http://blocks.fhcrc.org/>.

Sean Eddy recently wrote a paper reviewing the BLOSUM62 substitution matrix and how to calculate the scores [Eddy, 2004].

Use of scoring matrices

Deciding which scoring matrix you should use in order to obtain the best alignment results is a difficult task. If you have no prior knowledge on the sequence the BLOSUM62 is probably the best choice. This matrix has become the *de facto* standard for scoring matrices and is also used as the default matrix in BLAST searches. The selection of a "wrong" scoring matrix will most probably strongly influence on the outcome of the analysis. In general a few rules apply to the selection of scoring matrices.

- For closely related sequences choose BLOSUM matrices created for highly similar alignments, like BLOSUM80. You can also select low PAM matrices such as PAM1.
- For distant related sequences, select low BLOSUM matrices (for example BLOSUM45) or high PAM matrices such as PAM250.

The BLOSUM matrices with low numbers correspond to PAM matrices with high numbers. (See figure 15.13) for correlations between the PAM and BLOSUM matrices. To summarize, if you want to find distant related proteins to a sequence of interest using BLAST, you could benefit of using BLOSUM45 or similar matrices.

Other useful resources

Figure 15.13: Relationship between scoring matrices. The BLOSUM62 has become a de facto standard scoring matrix for a wide range of alignment programs. It is the default matrix in BLAST.

15.3 Local complexity plot

In *CLC Main Workbench* it is possible to calculate local complexity for both DNA and protein sequences. The local complexity is a measure of the diversity in the composition of amino acids within a given range (window) of the sequence. The K2 algorithm is used for calculating local complexity [Wootton and Federhen, 1993]. To conduct a complexity calculation do the following:

Select sequences in Navigation Area | Toolbox in Menu Bar | General Sequence Analysis (📁) | **Create Complexity Plot** (📊)

This opens a dialog. In **Step 1** you can change, remove and add DNA and protein sequences.

When the relevant sequences are selected, clicking **Next** takes you to **Step 2**. This step allows you to adjust the window size from which the complexity plot is calculated. Default is set to 11 amino acids and the number should always be odd. The higher the number, the less volatile the graph.

Figure 15.14 shows an example of a local complexity plot.

Figure 15.14: An example of a local complexity plot.

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**. The values of the complexity plot approaches 1.0 as the distribution of amino acids become more complex.

See section B in the appendix for information about the graph view.

15.4 Sequence statistics

CLC Main Workbench can produce an output with many relevant statistics for protein sequences. Some of the statistics are also relevant to produce for DNA sequences. Therefore, this section deals with both types of statistics. The required steps for producing the statistics are the same.

To create a statistic for the sequence, do the following:

select sequence(s) | Toolbox in the Menu Bar | General Sequence Analysis (🔧) | Create Sequence Statistics (📊)

This opens a dialog where you can alter your choice of sequences which you want to create statistics for. You can also add sequence lists.

Note! You cannot create statistics for DNA and protein sequences at the same time.

When the sequences are selected, click **Next**.

This opens the dialog displayed in figure 15.15.

The dialog offers to adjust the following parameters:

- **Individual statistics layout.** If more sequences were selected in **Step 1**, this function generates separate statistics for each sequence.
- **Comparative statistics layout.** If more sequences were selected in **Step 1**, this function generates statistics with comparisons between the sequences.

Figure 15.15: Setting parameters for the sequence statistics.

You can also choose to include Background distribution of amino acids. If this box is ticked, an extra column with amino acid distribution of the chosen species, is included in the table output. (The distributions are calculated from UniProt www.uniprot.org version 6.0, dated September 13 2005.)

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**. An example of protein sequence statistics is shown in figure 15.16.

1 Protein statistics

1.1 Sequence information

Sequence type	Protein
Length	147
Organism	Mus musculus
Name	CAA32220
Description	haemoglobin beta-h0 chain [Mus musculus]
Modification Date	18-APR-2005
Weight	16,412 kDa

1.2 Half-life

N-terminal aa	Half-life mammals	Half-life yeast	Half-life E.Coli

Figure 15.16: Comparative sequence statistics.

Nucleotide sequence statistics are generated using the same dialog as used for protein sequence statistics. However, the output of Nucleotide sequence statistics is less extensive than that of the protein sequence statistics.

Note! The headings of the tables change depending on whether you calculate 'individual' or 'comparative' sequence statistics.

The output of comparative protein sequence statistics include:

- Sequence information:
 - Sequence type
 - Length
 - Organism

- Name
 - Description
 - Modification Date
 - Weight. This is calculated like this: $sum_{unitsinsequence}(weight(unit)) - links * weight(H2O)$ where `links` is the sequence length minus one and `units` are amino acids. The atomic composition is defined the same way.
 - Isoelectric point
 - Aliphatic index
- Half-life
 - Extinction coefficient
 - Counts of Atoms
 - Frequency of Atoms
 - Count of hydrophobic and hydrophilic residues
 - Frequencies of hydrophobic and hydrophilic residues
 - Count of charged residues
 - Frequencies of charged residues
 - Amino acid distribution
 - Histogram of amino acid distribution
 - Annotation table
 - Counts of di-peptides
 - Frequency of di-peptides

The output of nucleotide sequence statistics include:

- General statistics:
 - Sequence type
 - Length
 - Organism
 - Name
 - Description
 - Modification Date
 - Weight. This is calculated like this: $sum_{unitsinsequence}(weight(unit)) - links * weight(H2O)$ where `links` is the sequence length minus one for linear sequences and sequence length for circular molecules. The `units` are monophosphates. Both the weight for single- and double stranded molecules are included. The atomic composition is defined the same way.

- Atomic composition
- Nucleotide distribution table
- Nucleotide distribution histogram
- Annotation table
- Counts of di-nucleotides
- Frequency of di-nucleotides

A short description of the different areas of the statistical output is given in section [15.4.1](#).

15.4.1 Bioinformatics explained: Protein statistics

Every protein holds specific and individual features which are unique to that particular protein. Features such as isoelectric point or amino acid composition can reveal important information of a novel protein. Many of the features described below are calculated in a simple way.

Molecular weight

The molecular weight is the mass of a protein or molecule. The molecular weight is simply calculated as the sum of the atomic mass of all the atoms in the molecule.

The weight of a protein is usually represented in Daltons (Da).

A calculation of the molecular weight of a protein does not usually include additional posttranslational modifications. For native and unknown proteins it tends to be difficult to assess whether posttranslational modifications such as glycosylations are present on the protein, making a calculation based solely on the amino acid sequence inaccurate. The molecular weight can be determined very accurately by mass-spectrometry in a laboratory.

Isoelectric point

The isoelectric point (pI) of a protein is the pH where the proteins has no net charge. The pI is calculated from the pKa values for 20 different amino acids. At a pH below the pI, the protein carries a positive charge, whereas if the pH is above pI the proteins carry a negative charge. In other words, pI is high for basic proteins and low for acidic proteins. This information can be used in the laboratory when running electrophoretic gels. Here the proteins can be separated, based on their isoelectric point.

Aliphatic index

The aliphatic index of a protein is a measure of the relative volume occupied by aliphatic side chain of the following amino acids: alanine, valine, leucine and isoleucine. An increase in the aliphatic index increases the thermostability of globular proteins. The index is calculated by the following formula.

$$\text{Aliphatic index} = X(\text{Ala}) + a * X(\text{Val}) + b * X(\text{Leu}) + b * (X)\text{Ile}$$

Amino acid	Mammalian	Yeast	E. coli
Ala (A)	4.4 hour	>20 hours	>10 hours
Cys (C)	1.2 hours	>20 hours	>10 hours
Asp (D)	1.1 hours	3 min	>10 hours
Glu (E)	1 hour	30 min	>10 hours
Phe (F)	1.1 hours	3 min	2 min
Gly (G)	30 hours	>20 hours	>10 hours
His (H)	3.5 hours	10 min	>10 hours
Ile (I)	20 hours	30 min	>10 hours
Lys (K)	1.3 hours	3 min	2 min
Leu (L)	5.5 hours	3 min	2 min
Met (M)	30 hours	>20 hours	>10 hours
Asn (N)	1.4 hours	3 min	>10 hours
Pro (P)	>20 hours	>20 hours	?
Gln (Q)	0.8 hour	10 min	>10 hours
Arg (R)	1 hour	2 min	2 min
Ser (S)	1.9 hours	>20 hours	>10 hours
Thr (T)	7.2 hours	>20 hours	>10 hours
Val (V)	100 hours	>20 hours	>10 hours
Trp (W)	2.8 hours	3 min	2 min
Tyr (Y)	2.8 hours	10 min	2 min

Table 15.2: **Estimated half life.** Half life of proteins where the N-terminal residue is listed in the first column and the half-life in the subsequent columns for mammals, yeast and *E. coli*.

$X(Ala)$, $X(Val)$, $X(Ile)$ and $X(Leu)$ are the amino acid compositional fractions. The constants a and b are the relative volume of valine ($a=2.9$) and leucine/isoleucine ($b=3.9$) side chains compared to the side chain of alanine [Ikai, 1980].

Estimated half-life

The half life of a protein is the time it takes for the protein pool of that particular protein to be reduced to the half. The half life of proteins is highly dependent on the presence of the N-terminal amino acid, thus overall protein stability [Bachmair et al., 1986, Gonda et al., 1989, Tobias et al., 1991]. The importance of the N-terminal residues is generally known as the 'N-end rule'. The N-end rule and consequently the N-terminal amino acid, simply determines the half-life of proteins. The estimated half-life of proteins have been investigated in mammals, yeast and *E. coli* (see Table 15.2). If leucine is found N-terminally in mammalian proteins the estimated half-life is 5.5 hours.

Extinction coefficient

This measure indicates how much light is absorbed by a protein at a particular wavelength. The extinction coefficient is measured by UV spectrophotometry, but can also be calculated. The amino acid composition is important when calculating the extinction coefficient. The extinction coefficient is calculated from the absorbance of cysteine, tyrosine and tryptophan using the following equation:

$$Ext(Protein) = count(Cysteine) * Ext(Cysteine) + count(Tyr) * Ext(Tyr) + count(Trp) * Ext(Trp)$$

where Ext is the extinction coefficient of amino acid in question. At 280nm the extinction coefficients are: Cys=120, Tyr=1280 and Trp=5690.

This equation is only valid under the following conditions:

- pH 6.5
- 6.0 M guanidium hydrochloride
- 0.02 M phosphate buffer

The extinction coefficient values of the three important amino acids at different wavelengths are found in [Gill and von Hippel, 1989].

Knowing the extinction coefficient, the absorbance (optical density) can be calculated using the following formula:

$$Absorbance(Protein) = \frac{Ext(Protein)}{Molecular\ weight}$$

Two values are reported. The first value is computed assuming that all cysteine residues appear as half cystines, meaning they form di-sulfide bridges to other cysteines. The second number assumes that no di-sulfide bonds are formed.

Atomic composition

Amino acids are indeed very simple compounds. All 20 amino acids consist of combinations of only five different atoms. The atoms which can be found in these simple structures are: Carbon, Nitrogen, Hydrogen, Sulfur, Oxygen. The atomic composition of a protein can for example be used to calculate the precise molecular weight of the entire protein.

Total number of negatively charged residues (Asp+Glu)

At neutral pH, the fraction of negatively charged residues provides information about the location of the protein. Intracellular proteins tend to have a higher fraction of negatively charged residues than extracellular proteins.

Total number of positively charged residues (Arg+Lys)

At neutral pH, nuclear proteins have a high relative percentage of positively charged amino acids. Nuclear proteins often bind to the negatively charged DNA, which may regulate gene expression or help to fold the DNA. Nuclear proteins often have a low percentage of aromatic residues [Andrade et al., 1998].

Amino acid distribution

Amino acids are the basic components of proteins. The amino acid distribution in a protein is simply the percentage of the different amino acids represented in a particular protein of interest. Amino acid composition is generally conserved through family-classes in different organisms which can be useful when studying a particular protein or enzymes across species borders. Another interesting observation is that amino acid composition variate slightly between

proteins from different subcellular localizations. This fact has been used in several computational methods, used for prediction of subcellular localization.

Annotation table

This table provides an overview of all the different annotations associated with the sequence and their incidence.

Dipeptide distribution

This measure is simply a count, or frequency, of all the observed adjacent pairs of amino acids (dipeptides) found in the protein. It is only possible to report neighboring amino acids. Knowledge on dipeptide composition have previously been used for prediction of subcellular localization.

15.5 Join sequences

CLC Main Workbench can join several nucleotide or protein sequences into one sequence. This feature can for example be used to construct "supergenes" for phylogenetic inference by joining several disjoint genes into one. Note, that when sequences are joined, all their annotations are carried over to the new spliced sequence.

Two (or more) sequences can be joined by:

select sequences to join | Toolbox in the Menu Bar | General Sequence Analyses | Join sequences (🔗)

or **select sequences to join | right-click any selected sequence | Toolbox | General Sequence Analyses | Join sequences (🔗)**

This opens the dialog shown in figure 15.17.

If you have selected some sequences before choosing the Toolbox action, they are now listed in the **Selected Elements** window of the dialog. Use the arrows to add or remove sequences from the selected elements. Click **Next** opens the dialog shown in figure 15.18.

In step 2 you can change the order in which the sequences will be joined. Select a sequence and use the arrows to move the selected sequence up or down.

Figure 15.17: Selecting two sequences to be joined.

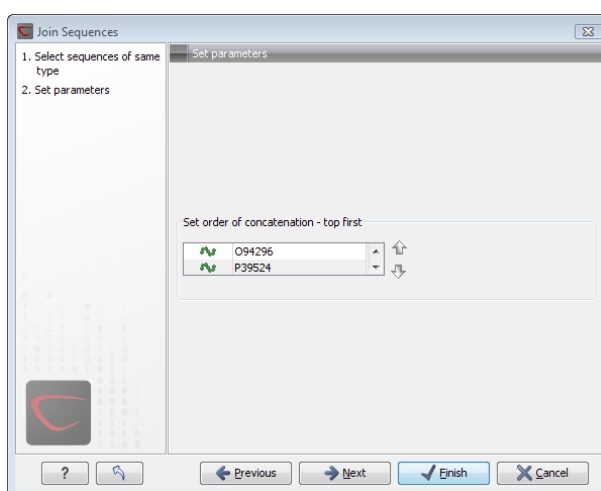

Figure 15.18: Setting the order in which sequences are joined.

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

The result is shown in figure 15.19.

Figure 15.19: The result of joining sequences is a new sequence containing the annotations of the joined sequences (they each had a HBB annotation).

15.6 Pattern Discovery

With *CLC Main Workbench* you can perform pattern discovery on both DNA and protein sequences. Advanced hidden Markov models can help to identify unknown sequence patterns across single or even multiple sequences.

In order to search for unknown patterns:

Select DNA or protein sequence(s) | Toolbox in the Menu Bar | General Sequence Analysis (📁) | Pattern Discovery (🔍?)

or **right-click DNA or protein sequence(s) | Toolbox | General Sequence Analysis (📁) | Pattern Discovery (🔍?)**

If a sequence was selected before choosing the Toolbox action, the sequence is now listed in the **Selected Elements** window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements.

You can perform the analysis on several DNA or several protein sequences at a time. If the analysis is performed on several sequences at a time the method will search for patterns which is common between all the sequences. Annotations will be added to all the sequences and a view is opened for each sequence.

Click **Next** to adjust parameters (see figure 15.20).

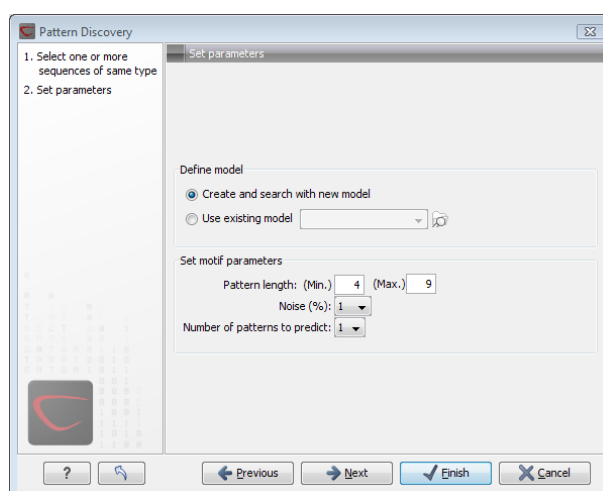

Figure 15.20: Setting parameters for the pattern discovery. See text for details.

In order to search unknown sequences with an already existing model:

Select to use an already existing model which is seen in figure 15.20. Models are represented with the following icon in the navigation area (🔍📁).

15.6.1 Pattern discovery search parameters

Various parameters can be set prior to the pattern discovery. The parameters are listed below and a screen shot of the parameter settings can be seen in figure 15.20.

- **Create and search with new model.** This will create a new HMM model based on the selected sequences. The found model will be opened after the run and presented in a table view. It can be saved and used later if desired.
- **Use existing model.** It is possible to use already created models to search for the same pattern in new sequences.
- **Minimum pattern length.** Here, the minimum length of patterns to search for, can be specified.

- **Maximum pattern length.** Here, the maximum length of patterns to search for, can be specified.
- **Noise (%).** Specify noise-level of the model. This parameter has influence on the level of degeneracy of patterns in the sequence(s). The noise parameter can be 1,2,5 or 10 percent.
- **Number of different kinds of patterns to predict.** Number of iterations the algorithm goes through. After the first iteration, we force predicted pattern-positions in the first run to be member of the background: In that way, the algorithm finds new patterns in the second iteration. Patterns marked 'Pattern1' have the highest confidence. The maximal iterations to go through is 3.
- **Include background distribution.** For protein sequences it is possible to include information on the background distribution of amino acids from a range of organisms.

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**. This will open a view showing the patterns found as annotations on the original sequence (see figure 15.21). If you have selected several sequences, a corresponding number of views will be opened.

```
      Pattern1      Pattern1
      ┌──────────┐ ┌──────────┐
3VCNKNQTA EDLAWSYGFP ECARFLTMIK CMQATARSSGE
```

Figure 15.21: Sequence view displaying two discovered patterns.

15.6.2 Pattern search output

If the analysis is performed on several sequences at a time the method will search for patterns in the sequences and open a new view for each of the sequences, in which a pattern was discovered. Each novel pattern will be represented as an annotation of the type **Region**. More information on each found pattern is available through the tool-tip, including detailed information on the position of the pattern and quality scores.

It is also possible to get a tabular view of all found patterns in one combined table. Then each found pattern will be represented with various information on obtained scores, quality of the pattern and position in the sequence.

A table view of emission values of the actual used HMM model is presented in a table view. This model can be saved and used to search for a similar pattern in new or unknown sequences.

15.7 Motif Search

CLC Main Workbench offers advanced and versatile options to search for known motifs represented either by a simple sequence or a more advanced regular expression. These advanced search capabilities are available for use in both DNA and protein sequences.

There are two ways to access this functionality:

- When viewing sequences, it is possible to have motifs calculated and shown on the sequence in a similar way as restriction sites (see section ??). This approach is called *Dynamic motifs* and is an easy way to spot known sequence motifs when working with sequences for cloning etc.
- For more refined and systematic search for motifs can be performed through the **Toolbox**. This will generate a table and optionally add annotations to the sequences.

The two approaches are described below.

15.7.1 Dynamic motifs

In the **Side Panel** of sequence views, there is a group called **Motifs** (see figure 15.22).

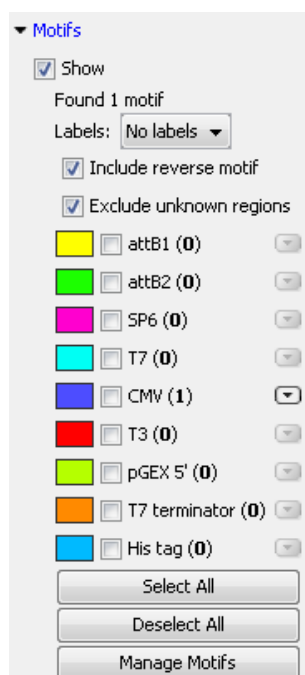

Figure 15.22: Dynamic motifs in the Side Panel.

The Workbench will look for the listed motifs in the sequence that is open and by clicking the check box next to the motif it will be shown in the view as illustrated in figure 15.23.

```

      380                400                420
      |                |                |
      CCCATTGACGTC AATGGGAGTTTGT TTTGGCCACCAAAATCAACGGGACTTTCC
      |                |                |
      440                460
      |                |
      AAAATGTCGTAACA AACTCCGCCCCATTGACGCAAAATGGGCGGTAGGCGTATAC
      |                |                |
      480                500                520
      |                |                |
      GGTGGGAGGTCTATATAAGCAGAGCTCGTTT AGTGAACCGTCAGATCGCCTGG
  
```

Figure 15.23: Showing dynamic motifs on the sequence.

This case shows the CMV promoter primer sequence which is one of the pre-defined motifs in *CLC Main Workbench*. The motif is per default shown as a faded arrow with no text. The direction of the arrow indicates the strand of the motif.

Placing the mouse cursor on the arrow will display additional information about the motif as illustrated in figure 15.24.

Figure 15.24: Showing dynamic motifs on the sequence.

To add **Labels** to the motif, select the **Flag** or **Stacked** option. They will put the name of the motif as a flag above the sequence. The stacked option will stack the labels when there is more than one motif so that all labels are shown.

Below the labels option there are two options for controlling the way the sequence should be searched for motifs:

- **Include reverse motifs.** This will also find motifs on the negative strand (only available for nucleotide sequences)
- **Exclude matches in N-regions for simple motifs.** The motif search handles ambiguous characters in the way that two residues are different if they do not have any residues in common. For example: For nucleotides, *N* matches any character and *R* matches *A,G*. For proteins, *X* matches any character and *Z* matches *E,Q*. Genome sequence often have large regions with unknown sequence. These regions are very often padded with *N*'s. Ticking this checkbox will not display hits found in *N*-regions and if a one residue in a motif matches to an *N*, it will be treated as a mismatch.

The list of motifs shown in figure 15.22 is a pre-defined list that is included with the *CLC Main Workbench*. You can define your own set of motifs to use instead. In order to do this, you first need to create a **Motif list** (📁) (see section 15.7.4) and then click the **Manage Motifs** button. This will bring up the dialog shown in figure 15.25.

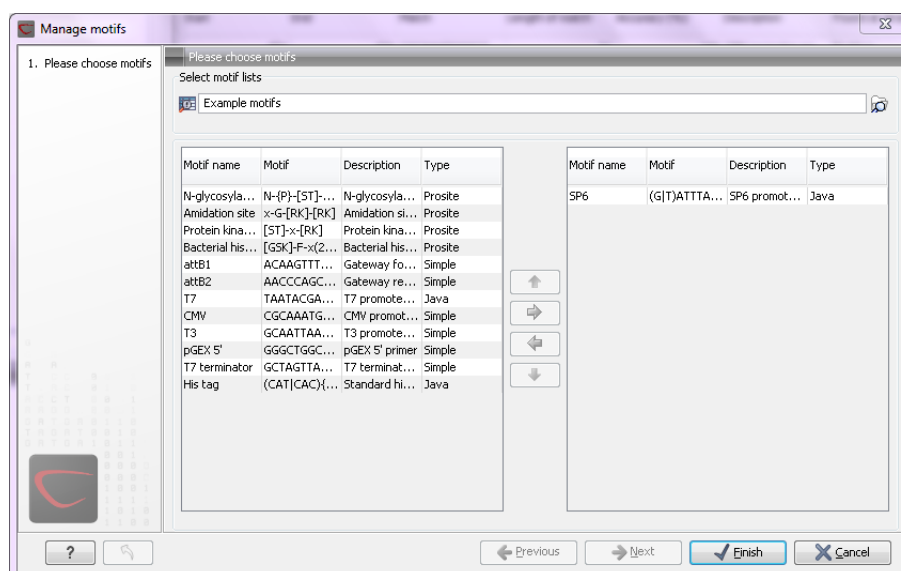

Figure 15.25: Managing the motifs to be shown.

At the top, select a motif list by clicking the **Browse**  button. When the motif list is selected, its motifs are listed in the panel in the left-hand side of the dialog. The right-hand side panel contains the motifs that will be listed in the **Side Panel** when you click **Finish**.

15.7.2 Motif search from the Toolbox

The dynamic motifs described in section 15.7.1 provide a quick way of routinely scanning a sequence for commonly used motifs, but in some cases a more systematic approach is needed. The motif search in the **Toolbox** provides an option to search for motifs with a user-specified similarity to the target sequence, and furthermore the motifs found can be displayed in an overview table. This is particularly useful when searching for motifs on many sequences.

To start the Toolbox motif search:

Toolbox | General Sequence Analysis | Motif Search

Use the arrows to add or remove sequences or sequence lists from the selected elements.

You can perform the analysis on several DNA or several protein sequences at a time. If the analysis is performed on several sequences at a time the method will search for patterns in the sequences and create an overview table of the motifs found in all sequences.

Click **Next** to adjust parameters (see figure 15.26).

Figure 15.26: Setting parameters for the motif search.

The options for the motif search are:

- **Motif types.** Choose what kind of motif to be used:
 - Simple motif. Choosing this option means that you enter a simple motif, e.g. ATGATGNNATG.
 - Java regular expression. See section 15.7.3.
 - Prosite regular expression. For proteins, you can enter different protein patterns from the PROSITE database (protein patterns using regular expressions and describing specific amino acid sequences). The PROSITE database contains a great number of patterns and have been used to identify related proteins (see <http://www.expasy.org/cgi-bin/prosite-list.pl>).

- Use motif list. Clicking the small button  will allow you to select a saved motif list (see section 15.7.4).
- **Motif.** If you choose to search with a simple motif, you should enter a literal string as your motif. Ambiguous amino acids and nucleotides are allowed. Example; ATGATGNNATG. If your motif type is Java regular expression, you should enter a regular expression according to the syntax rules described in section 15.7.3. Press **Shift + F1** key for options. For proteins, you can search with a Prosite regular expression and you should enter a protein pattern from the PROSITE database.
- **Accuracy.** If you search with a simple motif, you can adjust the accuracy of the motif to the match on the sequence. If you type in a simple motif and let the accuracy be 80%, the motif search algorithm runs through the input sequence and finds all subsequences of the same length as the simple motif such that the fraction of identity between the subsequence and the simple motif is at least 80%. A motif match is added to the sequence as an annotation with the exact fraction of identity between the subsequence and the simple motif. If you use a list of motifs, the accuracy applies only to the simple motifs in the list.
- **Search for reverse motif.** This enables searching on the negative strand on nucleotide sequences.
- **Exclude unknown regions.** Genome sequence often have large regions with unknown sequence. These regions are very often padded with N's. Ticking this checkbox will not display hits found in N-regions. Motif search handles ambiguous characters in the way that two residues are different if they do not have any residues in common. For example: For nucleotides, *N* matches any character and *R* matches *A,G*. For proteins, *X* matches any character and *Z* matches *E,Q*.

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**. There are two types of results that can be produced:

- **Add annotations.** This will add an annotation to the sequence when a motif is found (an example is shown in figure 15.27).
- **Create table.** This will create an overview table of all the motifs found for all the input sequences.

Figure 15.27: Sequence view displaying the pattern found. The search string was 'tataaa'.

15.7.3 Java regular expressions

A regular expressions is a string that describes or matches a set of strings, according to certain syntax rules. They are usually used to give a concise description of a set, without

having to list all elements. The simplest form of a regular expression is a literal string. The syntax used for the regular expressions is the Java regular expression syntax (see <http://java.sun.com/docs/books/tutorial/essential/regex/index.html>). Below is listed some of the most important syntax rules which are also shown in the help pop-up when you press Shift + F1:

$[A-Z]$ will match the characters A through Z (Range). You can also put single characters between the brackets: The expression $[AGT]$ matches the characters A , G or T .

$[A-D[M-P]]$ will match the characters A through D and M through P (Union). You can also put single characters between the brackets: The expression $[AG[M-P]]$ matches the characters A , G and M through P .

$[A-M\&\&[H-P]]$ will match the characters between A and M lying between H and P (Intersection). You can also put single characters between the brackets. The expression $[A-M\&\&[HGTD]]$ matches the characters A through M which is H , G , T , D or A .

$[^A-M]$ will match any character except those between A and M (Excluding). You can also put single characters between the brackets: The expression $[^AG]$ matches any character except A and G .

$[A-Z\&\&[^M-P]]$ will match any character A through Z except those between M and P (Subtraction). You can also put single characters between the brackets: The expression $[A-P\&\&[^CG]]$ matches any character between A and P except C and G .

The symbol $.$ matches any character.

$X\{n\}$ will match a repetition of an element indicated by following that element with a numerical value or a numerical range between the curly brackets. For example, $ACG\{2\}$ matches the string $ACGG$ and $(ACG)\{2\}$ matches $ACGACG$.

$X\{n,m\}$ will match a certain number of repetitions of an element indicated by following that element with two numerical values between the curly brackets. The first number is a lower limit on the number of repetitions and the second number is an upper limit on the number of repetitions. For example, $ACT\{1,3\}$ matches ACT , $ACTT$ and $ACTTT$.

$X\{n,\}$ represents a repetition of an element at least n times. For example, $(AC)\{2,\}$ matches all strings $ACAC$, $ACACAC$, $ACACACAC$,...

The symbol $^$ restricts the search to the beginning of your sequence. For example, if you search through a sequence with the regular expression AC , the algorithm will find a match if AC occurs in the beginning of the sequence.

The symbol $\$$ restricts the search to the end of your sequence. For example, if you search through a sequence with the regular expression $GT\$$, the algorithm will find a match if GT occurs in the end of the sequence.

Examples

The expression $[ACG][^AC]G\{2\}$ matches all strings of length 4, where the first character is A , C or G and the second is any character except A , C and the third and fourth character is G . The expression $G.[^A]\$$ matches all strings of length 3 in the end of your sequence, where the first character is C , the second any character and the third any character except A .

15.7.4 Create motif list

CLC Main Workbench offers advanced and versatile options to create lists of sequence patterns or known motifs represented either by a literal string or a regular expression.

A motif list is created from the Toolbox:

Toolbox | General Sequence Analyses | Create Motif List (📄)

This will open an empty list where you can add motifs by clicking the **Add** (+) button at the bottom of the view. This will open a dialog shown in figure 15.28.

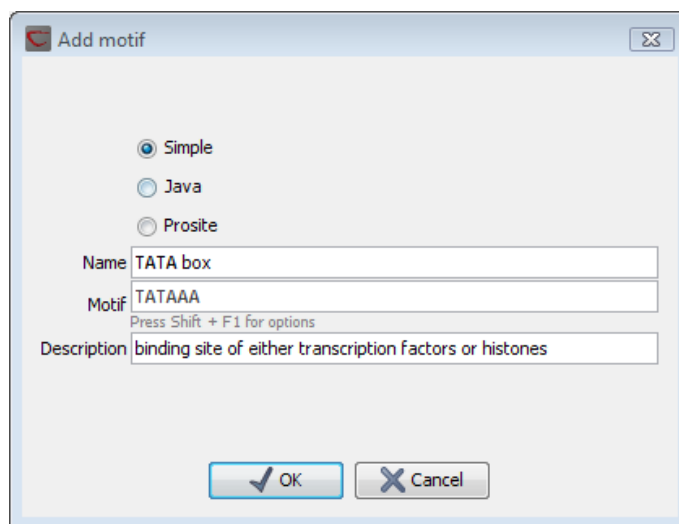

Figure 15.28: Entering a new motif in the list.

In this dialog, you can enter the following information:

- **Name.** The name of the motif. In the result of a motif search, this name will appear as the name of the annotation and in the result table.
- **Motif.** The actual motif. See section 15.7.2 for more information about the syntax of motifs.
- **Description.** You can enter a description of the motif. In the result of a motif search, the description will appear in the result table and added as a note to the annotation on the sequence (visible in the **Annotation table** (📄) or by placing the mouse cursor on the annotation).
- **Type.** You can enter three different types of motifs: Simple motifs, java regular expressions or PROSITE regular expression. Read more in section 15.7.2.

The motif list can contain a mix of different types of motifs. This is practical because some motifs can be described with the simple syntax, whereas others need the more advanced regular expression syntax.

Instead of manually adding motifs, you can **Import From Fasta File** (📄). This will show a dialog where you can select a fasta file on your computer and use this to create motifs. This will automatically take the name, description and sequence information from the fasta file, and put it into the motif list. The motif type will be "simple".

Besides adding new motifs, you can also edit and delete existing motifs in the list. To edit a motif, either double-click the motif in the list, or select and click the **Edit** () button at the bottom of the view.

To delete a motif, select it and press the Delete key on the keyboard. Alternatively, click **Delete** () in the **Tool bar**.

Save the motif list in the **Navigation Area**, and you will be able to use for Motif Search () (see section 15.7).

Chapter 16

Nucleotide analyses

Contents

16.1 Convert DNA to RNA	301
16.2 Convert RNA to DNA	302
16.3 Reverse complements of sequences	303
16.4 Reverse sequence	304
16.5 Translation of DNA or RNA to protein	304
16.5.1 Translate part of a nucleotide sequence	306
16.6 Find open reading frames	306
16.6.1 Open reading frame parameters	306

CLC Main Workbench offers different kinds of sequence analyses, which only apply to DNA and RNA.

16.1 Convert DNA to RNA

CLC Main Workbench lets you convert a DNA sequence into RNA, substituting the T residues (Thymine) for U residues (Urasil):

select a DNA sequence in the Navigation Area | Toolbox in the Menu Bar | Nucleotide Analysis (📄) | Convert DNA to RNA (🔗)

or **right-click a sequence in Navigation Area | Toolbox | Nucleotide Analysis (📄) | Convert DNA to RNA (🔗)**

This opens the dialog displayed in figure 16.1:

If a sequence was selected before choosing the Toolbox action, this sequence is now listed in the **Selected Elements** window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements.

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

Note! You can select multiple DNA sequences and sequence lists at a time. If the sequence list contains RNA sequences as well, they will not be converted.

Figure 16.1: Translating DNA to RNA.

16.2 Convert RNA to DNA

CLC Main Workbench lets you convert an RNA sequence into DNA, substituting the U residues (Urasil) for T residues (Thymine):

select an RNA sequence in the Navigation Area | Toolbox in the Menu Bar | Nucleotide Analysis (📁) | Convert RNA to DNA (🔄)

or **right-click a sequence in Navigation Area | Toolbox | Nucleotide Analysis (📁) | Convert RNA to DNA (🔄)**

This opens the dialog displayed in figure 16.2:

Figure 16.2: Translating RNA to DNA.

If a sequence was selected before choosing the Toolbox action, this sequence is now listed in the **Selected Elements** window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements.

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

This will open a new view in the **View Area** displaying the new DNA sequence. The new sequence is not saved automatically. To save the sequence, drag it into the **Navigation Area** or press Ctrl

+ S (⌘ + S on Mac) to activate a save dialog.

Note! You can select multiple RNA sequences and sequence lists at a time. If the sequence list contains DNA sequences as well, they will not be converted.

16.3 Reverse complements of sequences

CLC Main Workbench is able to create the reverse complement of a nucleotide sequence. By doing that, a new sequence is created which also has all the annotations reversed since they now occupy the opposite strand of their previous location.

To quickly obtain the reverse complement of a sequence or part of a sequence, you may select a region on the negative strand and open it in a new view:

right-click a selection on the negative strand | Open selection in New View (📄)

By doing that, the sequence will be reversed. This is only possible when the double stranded view option is enabled. It is possible to copy the selection and paste it in a word processing program or an e-mail. To obtain a reverse complement of an entire sequence:

select a sequence in the Navigation Area | Toolbox in the Menu Bar | Nucleotide Analysis (📄) | **Reverse Complement** (↔)

or **right-click a sequence in Navigation Area | Toolbox | Nucleotide Analysis** (📄) | **Reverse Complement** (↔)

This opens the dialog displayed in figure 16.3:

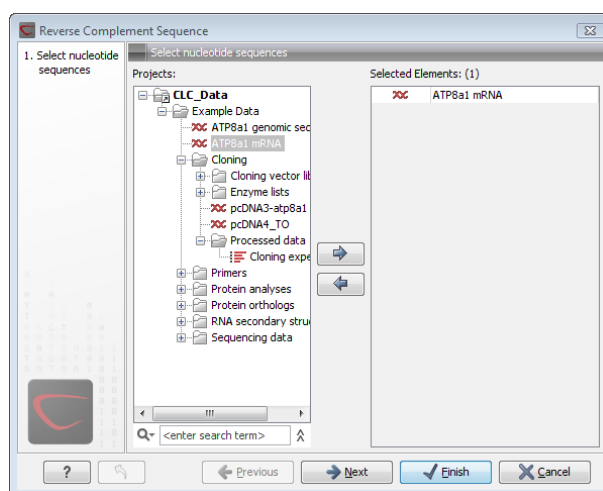

Figure 16.3: Creating a reverse complement sequence.

If a sequence was selected before choosing the Toolbox action, the sequence is now listed in the **Selected Elements** window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements.

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

This will open a new view in the **View Area** displaying the reverse complement of the selected sequence. The new sequence is not saved automatically. To save the sequence, drag it into the **Navigation Area** or press Ctrl + S (⌘ + S on Mac) to activate a save dialog.

16.4 Reverse sequence

CLC Main Workbench is able to create the reverse of a nucleotide sequence.

Note! This is not the same as a reverse complement. If you wish to create the reverse complement, please refer to section 16.3.

select a sequence in the Navigation Area | Toolbox in the Menu Bar | Nucleotide Analysis (📄) | Reverse Sequence (↔)

This opens the dialog displayed in figure 16.4:

Figure 16.4: Reversing a sequence.

If a sequence was selected before choosing the Toolbox action, the sequence is now listed in the **Selected Elements** window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements.

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

Note! This is not the same as a reverse complement. If you wish to create the reverse complement, please refer to section 16.3.

16.5 Translation of DNA or RNA to protein

In *CLC Main Workbench* you can translate a nucleotide sequence into a protein sequence using the **Toolbox** tools. Usually, you use the +1 reading frame which means that the translation starts from the first nucleotide. Stop codons result in an asterisk being inserted in the protein sequence at the corresponding position. It is possible to translate in any combination of the six reading frames in one analysis. To translate:

select a nucleotide sequence | Toolbox in the Menu Bar | Nucleotide Analysis (📄) | Translate to Protein (🔄)

or **right-click a nucleotide sequence | Toolbox | Nucleotide Analysis (📄) | Translate to Protein (🔄)**

This opens the dialog displayed in figure 16.5:

If a sequence was selected before choosing the Toolbox action, the sequence is now listed in

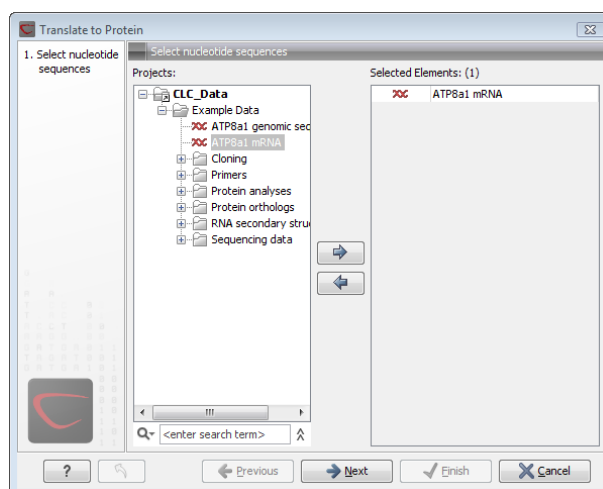

Figure 16.5: Choosing sequences for translation.

the **Selected Elements** window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements.

Clicking **Next** generates the dialog seen in figure 16.6:

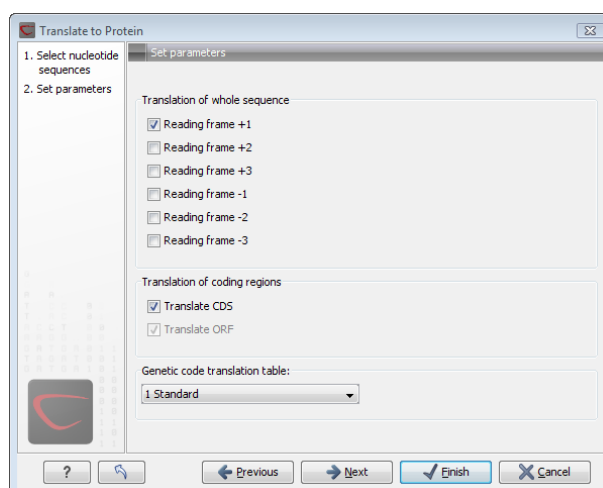

Figure 16.6: Choosing +1 and +3 reading frames, and the standard translation table.

Here you have the following options:

Reading frames If you wish to translate the whole sequence, you must specify the reading frame for the translation. If you select e.g. two reading frames, two protein sequences are generated.

Translate coding regions You can choose to translate regions marked by and CDS or ORF annotation. This will generate a protein sequence for each CDS or ORF annotation on the sequence.

Genetic code translation table Lets you specify the genetic code for the translation. The translation tables are occasionally updated from NCBI. The tables are not available in this printable version of the user manual. Instead, the tables are included in the **Help**-menu in the **Menu Bar** (in the appendix).

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**. The newly created protein is shown, but is not saved automatically.

To save a protein sequence, drag it into the **Navigation Area** or press Ctrl + S (⌘ + S on Mac) to activate a save dialog.

16.5.1 Translate part of a nucleotide sequence

If you want to make separate translations of *all* the coding regions of a nucleotide sequence, you can check the option: "Translate CDS and ORF" in the translation dialog (see figure 16.6).

If you want to translate a *specific* coding region, which is annotated on the sequence, use the following procedure:

Open the nucleotide sequence | right-click the ORF or CDS annotation | Translate CDS/ORF (👉) | choose a translation table | OK

If the annotation contains information about the translation, this information will be used, and you do not have to specify a translation table.

The CDS and ORF annotations are colored yellow as default.

16.6 Find open reading frames

The *CLC Main Workbench* **Find Open Reading Frames** function can be used to find all open reading frames (ORF) in a sequence, or, by choosing particular start codons to use, it can be used as a rudimentary gene finder. ORFs identified will be shown as annotations on the sequence. You have the option of choosing a translation table, the start codons to use, minimum ORF length as well as a few other parameters. These choices are explained in this section.

To find open reading frames:

select a nucleotide sequence | Toolbox in the Menu Bar | Nucleotide Analysis (📁) | Find Open Reading Frames (🔍)

or **right-click a nucleotide sequence | Toolbox | Nucleotide Analysis (📁) | Find Open Reading Frames (🔍)**

This opens the dialog displayed in figure 16.7:

If a sequence was selected before choosing the Toolbox action, the sequence is now listed in the **Selected Elements** window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements.

If you want to adjust the parameters for finding open reading frames click **Next**.

16.6.1 Open reading frame parameters

This opens the dialog displayed in figure 16.8:

The adjustable parameters for the search are:

- **Start codon:**

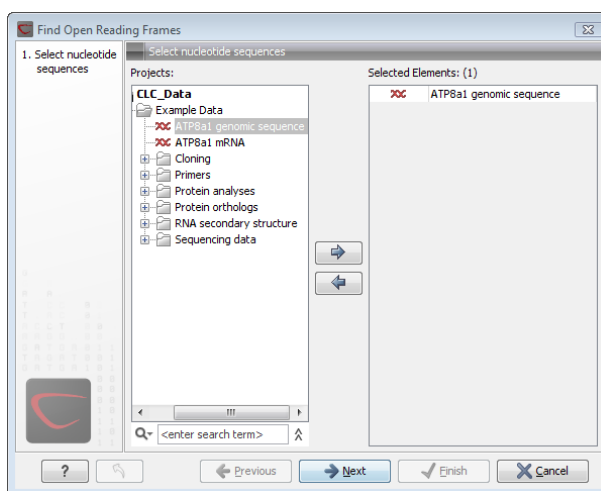

Figure 16.7: Create Reading Frame dialog.

Figure 16.8: Create Reading Frame dialog.

- **AUG**. Most commonly used start codon.
 - **Any**. Find all open reading frames.
 - **All start codons in genetic code**.
 - **Other**. Here you can specify a number of start codons separated by commas.
- **Both strands**. Finds reading frames on both strands.
 - **Open-ended Sequence**. Allows the ORF to start or end outside the sequence. If the sequence studied is a part of a larger sequence, it may be advantageous to allow the ORF to start or end outside the sequence.
 - **Genetic code translation table**.
 - **Include stop codon in result** The ORFs will be shown as annotations which can include the stop codon if this option is checked. The translation tables are occasionally updated from NCBI. The tables are not available in this printable version of the user manual. Instead, the tables are included in the **Help**-menu in the **Menu Bar** (in the appendix).
 - **Minimum Length**. Specifies the minimum length for the ORFs to be found. The length is specified as number of codons.

Using open reading frames for gene finding is a fairly simple approach which is likely to predict genes which are not real. Setting a relatively high minimum length of the ORFs will reduce the number of false positive predictions, but at the same time short genes may be missed (see figure 16.9).

Figure 16.9: The first 12,000 positions of the *E. coli* sequence NC_000913 downloaded from GenBank. The blue (dark) annotations are the genes while the yellow (brighter) annotations are the ORFs with a length of at least 100 amino acids. On the positive strand around position 11,000, a gene starts before the ORF. This is due to the use of the standard genetic code rather than the bacterial code. This particular gene starts with CTG, which is a start codon in bacteria. Two short genes are entirely missing, while a handful of open reading frames do not correspond to any of the annotated genes.

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

Finding open reading frames is often a good first step in annotating sequences such as cloning vectors or bacterial genomes. For eukaryotic genes, ORF determination may not always be very helpful since the intron/exon structure is not part of the algorithm.

Chapter 17

Protein analyses

Contents

17.1 Signal peptide prediction	310

CLC Main Workbench offers a number of analyses of proteins as described in this chapter.

17.1 Signal peptide prediction

Signal peptides target proteins to the extracellular environment either through direct plasma-membrane translocation in prokaryotes or is routed through the Endoplasmatic Reticulum in eukaryotic cells. The signal peptide is removed from the resulting mature protein during translocation across the membrane. For prediction of signal peptides, we query SignalP [Nielsen et al., 1997, Bendtsen et al., 2004b] located at <http://www.cbs.dtu.dk/services/SignalP/>. Thus an active internet connection is required to run the signal peptide prediction. Additional information on SignalP and Center for Biological Sequence analysis (CBS) can be found at <http://www.cbs.dtu.dk> and in the original research papers [Nielsen et al., 1997, Bendtsen et al., 2004b].

In order to predict potential signal peptides of proteins, the D-score from the SignalP output is used for discrimination of signal peptide versus non-signal peptide (see section 17.1.3). This score has been shown to be the most accurate [Klee and Ellis, 2005] in an evaluation study of signal peptide predictors.

In order to use SignalP, you need to download the SignalP plug-in using the plug-in manager, see section 1.7.1.

When the plug-in is downloaded and installed, you can use it to predict signal peptides:

Select a protein sequence | Toolbox in the Menu Bar | Protein Analysis (📁) | Signal Peptide Prediction (🌿)

or **right-click a protein sequence | Toolbox | Protein Analysis (📁) | Signal Peptide Prediction (🌿)**

If a sequence was selected before choosing the Toolbox action, this sequence is now listed in the **Selected Elements** window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements.

Click **Next** to set parameters for the SignalP analysis.

17.1.1 Signal peptide prediction parameter settings

It is possible to set different options prior to running the analysis (see figure 17.1). An organism type should be selected. The default is eukaryote.

- Eukaryote (default)
- Gram-negative bacteria
- Gram-positive bacteria

You can perform the analysis on several protein sequences at a time. This will add annotations to all the sequences and open a view for each sequence if a signal peptide is found. If no signal peptide is found in the sequence a dialog box will be shown.

The predictions obtained can either be shown as annotations on the sequence, listed in a table or be shown as the detailed and full text output from the SignalP method. This can be used to interpret borderline predictions:

- Add annotations to sequence

Figure 17.1: Setting the parameters for signal peptide prediction.

- Create table
- Text

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

17.1.2 Signal peptide prediction output

After running the prediction as described above, the protein sequence will show predicted signal peptide as annotations on the original sequence (see figure 17.2).

Figure 17.2: N-terminal signal peptide shown as annotation on the sequence.

Each annotation will carry a tooltip note saying that the corresponding annotation is predicted with SignalP version 3.0. Additional notes can be added through the **Edit annotation** (👉) right-click mouse menu. See section 11.3.2.

Undesired annotations can be removed through the **Delete Annotation** (👉) right-click mouse menu. See section 11.3.4.

17.1.3 Bioinformatics explained: Prediction of signal peptides

Why the interest in signal peptides?

The importance of signal peptides was shown in 1999 when Günter Blobel received the Nobel Prize in physiology or medicine for his discovery that "proteins have intrinsic signals that govern

their transport and localization in the cell" [Blobel, 2000]. He pointed out the importance of defined peptide motifs for targeting proteins to their site of function.

Performing a query to PubMed¹ reveals that thousands of papers have been published, regarding signal peptides, secretion and subcellular localization, including knowledge of using signal peptides as vehicles for chimeric proteins for biomedical and pharmaceutical industry. Many papers describe statistical or machine learning methods for prediction of signal peptides and prediction of subcellular localization in general. After the first published method for signal peptide prediction [von Heijne, 1986], more and more methods have surfaced, although not all methods have been made available publicly.

Different types of signal peptides

Soon after Günter Blobel's initial discovery of signal peptides, more targeting signals were found. Most cell types and organisms employ several ways of targeting proteins to the extracellular environment or subcellular locations. Most of the proteins targeted for the extracellular space or subcellular locations carry specific sequence motifs (signal peptides) characterizing the type of secretion/targeting it undergoes.

Several new different signal peptides or targeting signals have been found during the later years, and papers often describe a small amino acid motif required for secretion of that particular protein. In most of the latter cases, the identified sequence motif is only found in this particular protein and as such cannot be described as a new group of signal peptides.

Describing the various types of signal peptides is beyond the scope of this text but several review papers on this topic can be found on PubMed. Targeting motifs can either be removed from, or retained in the mature protein after the protein has reached the correct and final destination. Some of the best characterized signal peptides are depicted in figure 17.3.

Numerous methods for prediction of protein targeting and signal peptides have been developed; some of them are mentioned and cited in the introduction of the SignalP research paper [Bendtsen et al., 2004b]. However, no prediction method will be able to cover all the different types of signal peptides. Most methods predicts classical signal peptides targeting to the general secretory pathway in bacteria or classical secretory pathway in eukaryotes. Furthermore, a few methods for prediction of non-classically secreted proteins have emerged [Bendtsen et al., 2004a, Bendtsen et al., 2005].

Prediction of signal peptides and subcellular localization

In the search for accurate prediction of signal peptides, many approaches have been investigated. Almost 20 years ago, the first method for prediction of classical signal peptides was published [von Heijne, 1986]. Nowadays, more sophisticated machine learning methods, such as neural networks, support vector machines, and hidden Markov models have arrived along with the increasing computational power and they all perform superior to the old weight matrix based methods [Menne et al., 2000]. Also, many other "classical" statistical approaches have been carried out, often in conjunction with machine learning methods. In the following sections, a wide range of different signal peptide and subcellular prediction methods will be described.

Most signal peptide prediction methods require the presence of the correct N-terminal end of

¹<http://www.ncbi.nlm.nih.gov/entrez/>

Figure 17.3: Schematic representation of various signal peptides. Red color indicates n-region, gray color indicates h-region, cyan indicates c-region. All white circles are part of the mature protein. +1 indicates the first position of the mature protein. The length of the signal peptides is not drawn to scale.

the preprotein for correct classification. As large scale genome sequencing projects sometimes assign the 5'-end of genes incorrectly, many proteins are annotated without the correct N-terminal [Reinhardt and Hubbard, 1998] leading to incorrect prediction of subcellular localization. These erroneous predictions can be ascribed directly to poor gene finding. Other methods for prediction of subcellular localization use information within the mature protein and therefore they are more robust to N-terminal truncation and gene finding errors.

Figure 17.4: Sequence logo of eukaryotic signal peptides, showing conservation of amino acids in bits [Schneider and Stephens, 1990]. Polar and hydrophobic residues are shown in green and black, respectively, while blue indicates positively charged residues and red negatively charged residues. The logo is based on an ungapped sequence alignment fixed at the -1 position of the signal peptides.

The SignalP method

One of the most cited and best methods for prediction of classical signal peptides is the SignalP method [Nielsen et al., 1997, Bendtsen et al., 2004b]. In contrast to other methods, SignalP also predicts the actual cleavage site; thus the peptide which is cleaved off during translocation over the membrane. Recently, an independent research paper has rated SignalP version 3.0 to be the best standalone tool for signal peptide prediction. It was shown that the D-score which is reported by the SignalP method is the best measure for discriminating secretory from non-secretory proteins [Klee and Ellis, 2005].

SignalP is located at <http://www.cbs.dtu.dk/services/SignalP/>

What do the SignalP scores mean?

Many bioinformatics approaches or prediction tools do not give a yes/no answer. Often the user is facing an interpretation of the output, which can be either numerical or graphical. Why is that? In clear-cut examples there are no doubt; yes: this is a signal peptide! But, in borderline cases it is often convenient to have more information than just a yes/no answer. Here a graphical output can aid to interpret the correct answer. An example is shown in figure 17.5.

The graphical output from SignalP (neural network) comprises three different scores, C, S and Y. Two additional scores are reported in the SignalP3-NN output, namely the *S-mean* and the *D-score*, but these are only reported as numerical values.

For each organism class in SignalP; Eukaryote, Gram-negative and Gram-positive, two different neural networks are used, one for predicting the actual signal peptide and one for predicting the position of the signal peptidase I (SPase I) cleavage site. The *S-score* for the signal peptide prediction is reported for every single amino acid position in the submitted sequence, with high scores indicating that the corresponding amino acid is part of a signal peptide, and low scores indicating that the amino acid is part of a mature protein.

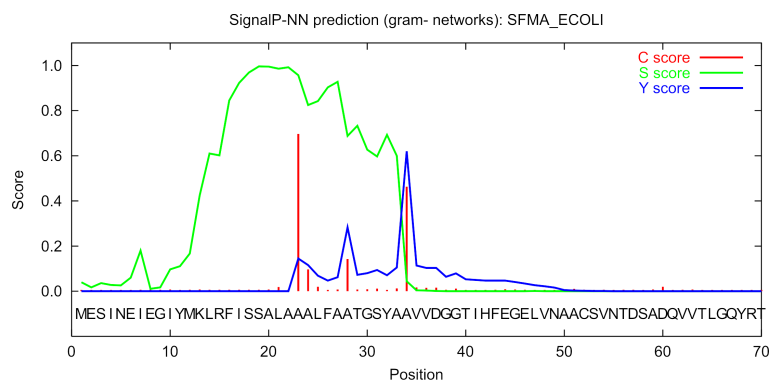

Figure 17.5: Graphical output from the SignalP method of Swiss-Prot entry *SFMA_ECOLI*. Initially this seemed like a borderline prediction, but closer inspection of the sequence revealed an internal methionine at position 12, which could indicate a erroneously annotated start of the protein. Later this protein was re-annotated by Swiss-Prot to start at the M in position 12. See the text for description of the scores.

The C-score is the "cleavage site" score. For each position in the submitted sequence, a C-score is reported, which should only be significantly high at the cleavage site. Confusion is often seen with the position numbering of the cleavage site. When a cleavage site position is referred to by a single number, the number indicates the first residue in the mature protein. This means that a reported cleavage site between amino acid 26-27 corresponds to the mature protein starting at (and include) position 27.

Y-max is a derivative of the C-score combined with the S-score resulting in a better cleavage site prediction than the raw C-score alone. This is due to the fact that multiple high-peaking C-scores can be found in one sequence, where only one is the true cleavage site. The cleavage site is assigned from the Y-score where the slope of the S-score is steep and a significant C-score is found.

The S-mean is the average of the S-score, ranging from the N-terminal amino acid to the amino acid assigned with the highest Y-max score, thus the S-mean score is calculated for the length of the predicted signal peptide. The S-mean score was in SignalP version 2.0 used as the criteria for discrimination of secretory and non-secretory proteins.

The D-score is introduced in SignalP version 3.0 and is a simple average of the S-mean and Y-max score. The score shows superior discrimination performance of secretory and non-secretory proteins to that of the S-mean score which was used in SignalP version 1 and 2.

For non-secretory proteins all the scores represented in the SignalP3-NN output should ideally be very low.

The hidden Markov model calculates the probability of whether the submitted sequence contains a signal peptide or not. The eukaryotic HMM model also reports the probability of a signal anchor, previously named uncleaved signal peptides. Furthermore, the cleavage site is assigned by a probability score together with scores for the n-region, h-region, and c-region of the signal peptide, if it is found.

17.2 Protein charge

In *CLC Main Workbench* you can create a graph in the electric charge of a protein as a function of pH. This is particularly useful for finding the net charge of the protein at a given pH. This knowledge can be used e.g. in relation to isoelectric focusing on the first dimension of 2D-gel electrophoresis. The isoelectric point (pI) is found where the net charge of the protein is zero. The calculation of the protein charge does not include knowledge about any potential post-translational modifications the protein may have.

The pKa values reported in the literature may differ slightly, thus resulting in different looking graphs of the protein charge plot compared to other programs.

In order to calculate the protein charge:

Select a protein sequence | Toolbox in the Menu Bar | Protein Analysis (📁) | Create Protein Charge Plot (📄)

or **right-click a protein sequence | Toolbox | Protein Analysis (📁) | Create Protein Charge Plot (📄)**

This opens the dialog displayed in figure 17.6:

If a sequence was selected before choosing the Toolbox action, the sequence is now listed in the **Selected Elements** window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements.

You can perform the analysis on several protein sequences at a time. This will result in one output graph showing protein charge graphs for the individual proteins.

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

Figure 17.6: Choosing protein sequences to calculate protein charge.

17.2.1 Modifying the layout

Figure 17.7 shows the electrical charges for three proteins. In the **Side Panel** to the right, you can modify the layout of the graph.

Figure 17.7: View of the protein charge.

See section B in the appendix for information about the graph view.

17.3 Transmembrane helix prediction

Many proteins are integral membrane proteins. Most membrane proteins have hydrophobic regions which span the hydrophobic core of the membrane bi-layer and hydrophilic regions located on the outside or the inside of the membrane. Many receptor proteins have several transmembrane helices spanning the cellular membrane.

For prediction of transmembrane helices, *CLC Main Workbench* uses TMHMM version 2.0 [Krogh et al., 2001] located at <http://www.cbs.dtu.dk/services/TMHMM/>, thus an active internet connection is required to run the transmembrane helix prediction. Additional information on THMHH and Center for Biological Sequence analysis (CBS) can be found at

<http://www.cbs.dtu.dk> and in the original research paper [Krogh et al., 2001].

In order to use the transmembrane helix prediction, *you need to download the plug-in* using the plug-in manager (see section 1.7.1).

When the plug-in is downloaded and installed, you can use it to predict transmembrane helices:

**Select a protein sequence | Toolbox in the Menu Bar | Protein Analysis (📁)|
Transmembrane Helix Prediction (🔍)**

or **right-click a protein sequence | Toolbox | Protein Analysis (📁)| Transmembrane
Helix Prediction (🔍)**

If a sequence was selected before choosing the Toolbox action, this sequence is now listed in the **Selected Elements** window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements.

The predictions obtained can either be shown as annotations on the sequence, in a table or as the detailed and text output from the TMHMM method.

- Add annotations to sequence
- Create table
- Text

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

You can perform the analysis on several protein sequences at a time. This will add annotations to all the sequences and open a view for each sequence if a transmembrane helix is found. If a transmembrane helix is not found a dialog box will be presented.

After running the prediction as described above, the protein sequence will show predicted transmembrane helices as annotations on the original sequence (see figure 17.8). Moreover, annotations showing the topology will be shown. That is, which part the proteins is located on the inside or on the outside.

Each annotation will carry a tooltip note saying that the corresponding annotation is predicted with TMHMM version 2.0. Additional notes can be added through the **Edit annotation** (👉) right-click mouse menu. See section 11.3.2.

Undesired annotations can be removed through the **Delete Annotation** (🗑️) right-click mouse menu. See section 11.3.4.

17.4 Antigenicity

CLC Main Workbench can help to identify antigenic regions in protein sequences in different ways, using different algorithms. The algorithms provided in the Workbench, merely plot an index of antigenicity over the sequence.

Two different methods are available.

[Welling et al., 1985] Welling et al. used information on the relative occurrence of amino acids in antigenic regions to make a scale which is useful for prediction of antigenic regions. This method

Figure 17.8: Transmembrane segments shown as annotation on the sequence and the topology.

is better than the Hopp-Woods scale of hydrophobicity which is also used to identify antigenic regions.

A semi-empirical method for prediction of antigenic regions has been developed [Kolaskar and Tongaonkar, 1990]. This method also includes information of surface accessibility and flexibility and at the time of publication the method was able to predict antigenic determinants with an accuracy of 75%.

Note! Similar results from the two method can not always be expected as the two methods are based on different training sets.

17.4.1 Plot of antigenicity

Displaying the antigenicity for a protein sequence in a plot is done in the following way:

select a protein sequence in Navigation Area | Toolbox in the Menu Bar | Protein Analysis (📄) | Create Antigenicity Plot (📊)

This opens a dialog. The first step allows you to add or remove sequences. Clicking **Next** takes you through to **Step 2**, which is displayed in figure 17.9.

The **Window size** is the width of the window where, the antigenicity is calculated. The wider the window, the less volatile the graph. You can chose from a number of antigenicity scales. Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**. The result can be seen in figure 17.10.

See section B in the appendix for information about the graph view.

The level of antigenicity is calculated on the basis of the different scales. The different scales add different values to each type of amino acid. The antigenicity score is then calculated as the

Figure 17.9: Step two in the Antigenicity Plot allows you to choose different antigenicity scales and the window size.

Figure 17.10: The result of the antigenicity plot calculation and the associated Side Panel.

sum of the values in a 'window', which is a particular range of the sequence. The window length can be set from 5 to 25 residues. The wider the window, the less fluctuations in the antigenicity scores.

17.4.2 Antigenicity graphs along sequence

Antigenicity graphs along the sequence can be displayed using the **Side Panel**. The functionality is similar to hydrophobicity (see section 17.5.2).

17.5 Hydrophobicity

CLC Main Workbench can calculate the hydrophobicity of protein sequences in different ways, using different algorithms. (See section 17.5.3). Furthermore, hydrophobicity of sequences can be displayed as hydrophobicity plots and as graphs along sequences. In addition, *CLC Main Workbench* can calculate hydrophobicity for several sequences at the same time, and for

alignments.

17.5.1 Hydrophobicity plot

Displaying the hydrophobicity for a protein sequence in a plot is done in the following way:

select a protein sequence in Navigation Area | Toolbox in the Menu Bar | Protein Analysis (📁) | Create Hydrophobicity Plot (📊)

This opens a dialog. The first step allows you to add or remove sequences. Clicking **Next** takes you through to **Step 2**, which is displayed in figure 17.11.

Figure 17.11: Step two in the Hydrophobicity Plot allows you to choose hydrophobicity scale and the window size.

The **Window size** is the width of the window where the hydrophobicity is calculated. The wider the window, the less volatile the graph. You can choose from a number of hydrophobicity scales which are further explained in section 17.5.3 Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**. The result can be seen in figure 17.12.

Figure 17.12: The result of the hydrophobicity plot calculation and the associated Side Panel.

See section **B** in the appendix for information about the graph view.

17.5.2 Hydrophobicity graphs along sequence

Hydrophobicity graphs along sequence can be displayed easily by activating the calculations from the **Side Panel** for a sequence.

right-click protein sequence in Navigation Area | Show | Sequence | open Protein info in Side Panel

or **double-click protein sequence in Navigation Area | Show | Sequence | open Protein info in Side Panel**

These actions result in the view displayed in figure 17.13.

Figure 17.13: The different available scales in Protein info in **CLC Main Workbench**.

The level of hydrophobicity is calculated on the basis of the different scales. The different scales add different values to each type of amino acid. The hydrophobicity score is then calculated as the sum of the values in a 'window', which is a particular range of the sequence. The window length can be set from 5 to 25 residues. The wider the window, the less fluctuations in the hydrophobicity scores. (For more about the theory behind hydrophobicity, see 17.5.3).

In the following we will focus on the different ways that *CLC Main Workbench* offers to display the hydrophobicity scores. We use Kyte-Doolittle to explain the display of the scores, but the different options are the same for all the scales. Initially there are three options for displaying the hydrophobicity scores. You can choose one, two or all three options by selecting the boxes. (See figure 17.14).

Figure 17.14: The different ways of displaying the hydrophobicity scores, using the Kyte-Doolittle scale.

Coloring the letters and their background. When choosing coloring of letters or coloring of their background, the color red is used to indicate high scores of hydrophobicity. A 'color-slider'

allows you to amplify the scores, thereby emphasizing areas with high (or low, blue) levels of hydrophobicity. The color settings mentioned are default settings. By clicking the color bar just below the color slider you get the option of changing color settings.

Graphs along sequences. When selecting graphs, you choose to display the hydrophobicity scores underneath the sequence. This can be done either by a line-plot or bar-plot, or by coloring. The latter option offers you the same possibilities of amplifying the scores as applies for coloring of letters. The different ways to display the scores when choosing 'graphs' are displayed in figure 17.14. Notice that you can choose the height of the graphs underneath the sequence.

17.5.3 Bioinformatics explained: Protein hydrophobicity

Calculation of hydrophobicity is important to the identification of various protein features. This can be membrane spanning regions, antigenic sites, exposed loops or buried residues. Usually, these calculations are shown as a plot along the protein sequence, making it easy to identify the location of potential protein features.

Figure 17.15: Plot of hydrophobicity along the amino acid sequence. Hydrophobic regions on the sequence have higher numbers according to the graph below the sequence, furthermore hydrophobic regions are colored on the sequence. Red indicates regions with high hydrophobicity and blue indicates regions with low hydrophobicity.

The hydrophobicity is calculated by sliding a fixed size window (of an odd number) over the protein sequence. At the central position of the window, the average hydrophobicity of the entire window is plotted (see figure 17.15).

Hydrophobicity scales

Several hydrophobicity scales have been published for various uses. Many of the commonly used hydrophobicity scales are described below.

Kyte-Doolittle scale. The Kyte-Doolittle scale is widely used for detecting hydrophobic regions in proteins. Regions with a positive value are hydrophobic. This scale can be used for identifying both surface-exposed regions as well as transmembrane regions, depending on the window size used. Short window sizes of 5-7 generally work well for predicting putative surface-exposed regions. Large window sizes of 19-21 are well suited for finding transmembrane domains if the values calculated are above 1.6 [Kyte and Doolittle, 1982]. These values should be used as a rule of thumb and deviations from the rule may occur.

Engelman scale. The Engelman hydrophobicity scale, also known as the GES-scale, is another scale which can be used for prediction of protein hydrophobicity [Engelman et al., 1986]. As the Kyte-Doolittle scale, this scale is useful for predicting transmembrane regions in proteins.

Eisenberg scale. The Eisenberg scale is a normalized consensus hydrophobicity scale which

shares many features with the other hydrophobicity scales [Eisenberg et al., 1984].

Hopp-Woods scale. Hopp and Woods developed their hydrophobicity scale for identification of potentially antigenic sites in proteins. This scale is basically a hydrophilic index where apolar residues have been assigned negative values. Antigenic sites are likely to be predicted when using a window size of 7 [Hopp and Woods, 1983].

Cornette scale. Cornette *et al.* computed an optimal hydrophobicity scale based on 28 published scales [Cornette et al., 1987]. This optimized scale is also suitable for prediction of alpha-helices in proteins.

Rose scale. The hydrophobicity scale by Rose *et al.* is correlated to the average area of buried amino acids in globular proteins [Rose et al., 1985]. This results in a scale which is not showing the helices of a protein, but rather the surface accessibility.

Janin scale. This scale also provides information about the accessible and buried amino acid residues of globular proteins [Janin, 1979].

Welling scale. Welling et al. used information on the relative occurrence of amino acids in antigenic regions to make a scale which is useful for prediction of antigenic regions. This method is better than the Hopp-Woods scale of hydrophobicity which is also used to identify antigenic regions.

Kolaskar-Tongaonkar. A semi-empirical method for prediction of antigenic regions has been developed [Kolaskar and Tongaonkar, 1990]. This method also includes information of surface accessibility and flexibility and at the time of publication the method was able to predict antigenic determinants with an accuracy of 75%.

Surface Probability. Display of surface probability based on the algorithm by [Emini et al., 1985]. This algorithm has been used to identify antigenic determinants on the surface of proteins.

Chain Flexibility. Display of backbone chain flexibility based on the algorithm by [Karplus and Schulz, 1985]. It is known that chain flexibility is an indication of a putative antigenic determinant.

Many more scales have been published throughout the last three decades. Even though more advanced methods have been developed for prediction of membrane spanning regions, the simple and very fast calculations are still highly used.

17.6 Pfam domain search

With *CLC Main Workbench* you can perform a search for Pfam domains on protein sequences. The Pfam database at <http://pfam.sanger.ac.uk/> is a large collection of multiple sequence alignments that covers approximately 9318 protein domains and protein families [Bateman et al., 2004]. Based on the individual domain alignments, profile HMMs have been developed. These profile HMMs can be used to search for domains in unknown sequences.

Many proteins have a unique combination of domains which can be responsible, for instance, for the catalytic activities of enzymes. Pfam was initially developed to aid the annotation of the *C. elegans* genome. Annotating unknown sequences based on pairwise alignment methods by simply transferring annotation from a known protein to the unknown partner does not take domain organization into account [Galperin and Koonin, 1998]. An unknown protein may be annotated wrongly, for instance, as an enzyme if the pairwise alignment only finds a regulatory domain.

Using the Pfam search option in *CLC Main Workbench*, you can search for domains in sequence data which otherwise do not carry any annotation information. The Pfam search option adds all found domains onto the protein sequence which was used for the search. If domains of no relevance are found they can easily be removed as described in section 11.3.4. Setting a lower cutoff value will result in fewer domains.

In *CLC Main Workbench* we have implemented our own HMM algorithm for prediction of the Pfam domains. Thus, we do not use the original HMM implementation, HMMER <http://hmmer.wustl.edu/> for domain prediction. We find the most probable state path/alignment through each profile HMM by the Viterbi algorithm and based on that we derive a new null model by averaging over the emission distributions of all *M* and *I* states that appear in the state path (*M* is a match state and *I* is an insert state). From that model we now arrive at an additive correction to the original bit-score, like it is done in the original HMMER algorithm.

In order to conduct the Pfam search:

Select a protein sequence | Toolbox in the Menu Bar | Protein Analysis (📁) | Pfam Domain Search (↔)

or **right-click a protein sequence | Toolbox | Protein Analysis (📁) | Pfam Domain Search (↔)**

Figure 17.16: Setting parameters for Pfam domain search.

If a sequence was selected before choosing the Toolbox action, this sequence is now listed in the **Selected Elements** window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements.

You can perform the analysis on several protein sequences at a time. This will add annotations to all the sequences and open a view for each sequence. Click **Next** to adjust parameters (see figure 17.16).

17.6.1 Pfam search parameters

- **Choose database and search type**

When searching for Pfam domains it is possible to choose different databases and specify the search for full domains or fragments of domains. Only the 100 most frequent domains are included as default in *CLC Main Workbench*. Additional databases can be downloaded directly from CLC bio's web-site at <http://www.clcbio.com/resources>.

- **Search full domains and fragments.** This option allows you to search both for full domain but also for partial domains. This could be the case if a domain extends beyond the ends of a sequence
- **Search full domains only.** Selecting this option only allows searches for full domains.

- **Search fragments only.** Only partial domains will be found.
- **Database.** Only the 100 most frequent domains are included as default in *CLC Main Workbench*, but additional databases can be downloaded and installed as described in section 17.6.2.
- **Set significance cutoff.** The E-value (expectation value) is the number of hits that would be expected to have a score equal to or better than this value, by chance alone. This means that a good E-value which gives a confident prediction is much less than 1. E-values around 1 is what is expected by chance. Thus, the lower the E-value, the more specific the search for domains will be. Only positive numbers are allowed.

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**. This will open a view showing the found domains as annotations on the original sequence (see figure 17.17). If you have selected several sequences, a corresponding number of views will be opened.

Figure 17.17: Domains annotations based on Pfam.

Each found domain will be represented as an annotation of the type **Region**. More information on each found domain is available through the tooltip, including detailed information on the identity score which is the basis for the prediction.

For a more detailed description of the provided scores through the tool tip look at <http://pfam.sanger.ac.uk/help#tabview=tab5>.

17.6.2 Download and installation of additional Pfam databases

Additional databases can be downloaded as a resource using the **Plug-in manager** (📦) (see section 1.7.4).

If you are not able to download directly from the Plug-in manager, please go to <http://www.clcbio.com/download> to download and install the files directly.

17.7 Secondary structure prediction

An important issue when trying to understand protein function is to know the actual structure of the protein. Many questions that are raised by molecular biologists are directly targeted at protein structure. The alpha-helix forms a coiled rodlike structure whereas a beta-sheet show an extended sheet-like structure. Some proteins are almost devoid of alpha-helices such as

chymotrypsin (PDB_ID: 1AB9) whereas others like myoglobin (PDB_ID: 101M) have a very high content of alpha-helices.

With *CLC Main Workbench* one can predict the secondary structure of proteins very fast. Predicted elements are alpha-helix, beta-sheet (same as beta-strand) and other regions.

Based on extracted protein sequences from the protein databank (<http://www.rcsb.org/pdb/>) a hidden Markov model (HMM) was trained and evaluated for performance. Machine learning methods have shown superior when it comes to prediction of secondary structure of proteins [Rost, 2001]. By far the most common structures are Alpha-helices and beta-sheets which can be predicted, and predicted structures are automatically added to the query as annotation which later can be edited.

In order to predict the secondary structure of proteins:

Select a protein sequence | Toolbox in the Menu Bar | Protein Analysis (📄) | Predict secondary structure (🌀)

or **right-click a protein sequence | Toolbox | Protein Analysis (📄) | Predict secondary structure (🌀)**

This opens the dialog displayed in figure 17.18:

Figure 17.18: Choosing one or more protein sequences for secondary structure prediction.

If a sequence was selected before choosing the Toolbox action, this sequence is now listed in the **Selected Elements** window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements.

You can perform the analysis on several protein sequences at a time. This will add annotations to all the sequences and open a view for each sequence.

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

After running the prediction as described above, the protein sequence will show predicted alpha-helices and beta-sheets as annotations on the original sequence (see figure 17.19).

Each annotation will carry a tooltip note saying that the corresponding annotation is predicted with *CLC Main Workbench*. Additional notes can be added through the **Edit Annotation** (👉) right-click mouse menu. See section 11.3.2.

Figure 17.19: Alpha-helices and beta-strands shown as annotations on the sequence.

Undesired alpha-helices or beta-sheets can be removed through the **Delete Annotation** (🗑️➡️) right-click mouse menu. See section 11.3.4.

17.8 Protein report

CLC Main Workbench is able to produce protein reports, that allow you to easily generate different kinds of information regarding a protein.

Actually a protein report is a collection of some of the protein analyses which are described elsewhere in this manual.

To create a protein report do the following:

Right-click protein in Navigation Area | Toolbox | Protein Analysis (📄) **Create Protein Report** (📄)

This opens dialog **Step 1**, where you can choose which proteins to create a report for. When the correct one is chosen, click **Next**.

In dialog **Step 2** you can choose which analyses you want to include in the report. The following list shows which analyses are available and explains where to find more details.

- **Sequence statistics.** See section 15.4 for more about this topic.
- **Plot of charge as function of pH.** See section 17.2 for more about this topic.
- **Plot of hydrophobicity.** See section 17.5 for more about this topic.
- **Plot of local complexity.** See section 15.3 for more about this topic.
- **Dot plot against self.** See section 15.2 for more about this topic.
- **Secondary structure prediction.** See section 17.7 for more about this topic.
- **Pfam domain search.** See section 17.6 for more about this topic.
- **Local BLAST.** See section 13.1.3 for more about this topic.
- **NCBI BLAST.** See section 13.1.1 for more about this topic.

When you have selected the relevant analyses, click **Next**. **Step 3 to Step 7** (if you select all the analyses in **Step 2**) are adjustments of parameters for the different analyses. The parameters

are mentioned briefly in relation to the following steps, and you can turn to the relevant chapters or sections (mentioned above) to learn more about the significance of the parameters.

In **Step 3** you can adjust parameters for sequence statistics:

- **Individual Statistics Layout. Comparative** is disabled because reports are generated for one protein at a time.
- **Include Background Distribution of Amino Acids.** Includes distributions from different organisms. Background distributions are calculated from UniProt www.uniprot.org version 6.0, dated September 13 2005.

In **Step 4** you can adjust parameters for hydrophobicity plots:

- **Window size.** Width of window on sequence (odd number).
- **Hydrophobicity scales.** Lets you choose between different scales.

In **Step 5** you can adjust a parameter for complexity plots:

- **Window size.** Width of window on sequence (must be odd).

In **Step 6** you can adjust parameters for dot plots:

- **Score model.** Different scoring matrices.
- **Window size.** Width of window on sequence.

In **Step 7** you can adjust parameters for BLAST search:

- **Program.** Lets you choose between different BLAST programs.
- **Database.** Lets you limit your search to a particular database.

17.8.1 Protein report output

An example of Protein report can be seen in figure [17.20](#).

By double clicking a graph in the output, this graph is shown in a different view (*CLC Main Workbench* generates another tab). The report output and the new graph views can be saved by dragging the tab into the **Navigation Area**.

The content of the tables in the report can be copy/pasted out of the program and e.g. into Microsoft Excel. To do so:

Select content of table | Right-click the selection | Copy

You can also **Export**  the report in Excel format.

1 Protein statistics

1.1 Sequence information

Sequence type	Protein
Length	47 nuc
Organism	Mus musculus (house mouse)
Name	CAA24102
Description	beta-globin HO [Mus musculus]
Modification Date	18-APR-2005
Weight	5.326,084 Da

N-terminal aa	Half-life mammals	Half-life yeast	Half-life E.Coli
Proline	>20 hours	>20 hours	Unknown

1.3 Extinction coefficient

Conditions	Extinction coefficient at	Absorption at 280nm 0.1%

Figure 17.20: A protein report. There is a Table of Contents in the Side Panel that makes it easy to browse the report.

17.9 Reverse translation from protein into DNA

A protein sequence can be back-translated into DNA using *CLC Main Workbench*. Due to degeneracy of the genetic code every amino acid could translate into several different codons (only 20 amino acids but 64 different codons). Thus, the program offers a number of choices for determining which codons should be used. These choices are explained in this section.

In order to make a reverse translation:

Select a protein sequence | Toolbox in the Menu Bar | Protein Analysis (📁) | Reverse Translate (🔄)

or **right-click a protein sequence | Toolbox | Protein Analysis (📁) | Reverse translate (🔄)**

This opens the dialog displayed in figure 17.21:

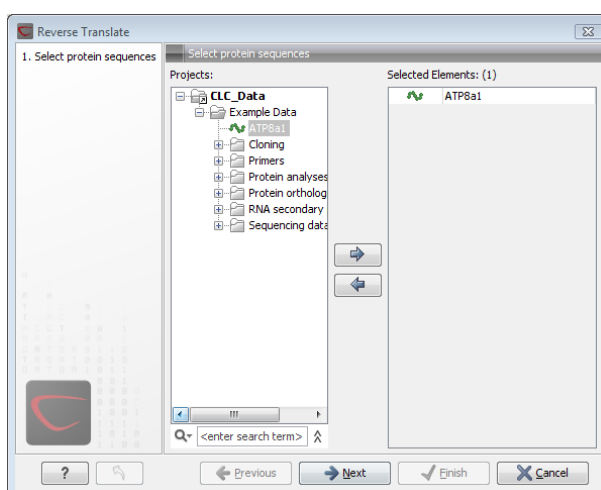

Figure 17.21: Choosing a protein sequence for reverse translation.

If a sequence was selected before choosing the Toolbox action, the sequence is now listed in the **Selected Elements** window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements. You can translate several protein sequences at a time.

Click **Next** to adjust the parameters for the translation.

17.9.1 Reverse translation parameters

Figure 17.22 shows the choices for making the translation.

Figure 17.22: Choosing parameters for the reverse translation.

- **Use random codon.** This will randomly back-translate an amino acid to a codon without using the translation tables. Every time you perform the analysis you will get a different result.
- **Use only the most frequent codon.** On the basis of the selected translation table, this parameter/option will assign the codon that occurs most often. When choosing this option, the results of performing several reverse translations will always be the same, contrary to the other two options.
- **Use codon based on frequency distribution.** This option is a mix of the other two options. The selected translation table is used to attach weights to each codon based on its frequency. The codons are assigned randomly with a probability given by the weights. A more frequent codon has a higher probability of being selected. Every time you perform the analysis, you will get a different result. This option yields a result that is closer to the translation behavior of the organism (assuming you choose an appropriate codon frequency table).
- **Map annotations to reverse translated sequence.** If this checkbox is checked, then all annotations on the protein sequence will be mapped to the resulting DNA sequence. In the tooltip on the transferred annotations, there is a note saying that the annotation derives from the original sequence.

The **Codon Frequency Table** is used to determine the frequencies of the codons. Select a frequency table from the list that fits the organism you are working with. A translation table of an organism is created on the basis of counting all the codons in the coding sequences. Every codon in a **Codon Frequency Table** has its own count, frequency (per thousand) and fraction which are calculated in accordance with the occurrences of the codon in the organism. You can customize the list of codon frequency tables for your installation, see section [L](#).

Click **Next** if you wish to adjust how to handle the results (see section [9.2](#)). If not, click **Finish**. The newly created nucleotide sequence is shown, and if the analysis was performed on several protein sequences, there will be a corresponding number of views of nucleotide sequences. The new sequence is not saved automatically. To save the sequence, drag it into the **Navigation Area** or press Ctrl + S (⌘ + S on Mac) to show the save dialog.

17.9.2 Bioinformatics explained: Reverse translation

In all living cells containing hereditary material such as DNA, a transcription to mRNA and subsequent a translation to proteins occur. This is of course simplified but is in general what is happening in order to have a steady production of proteins needed for the survival of the cell. In bioinformatics analysis of proteins it is sometimes useful to know the ancestral DNA sequence in order to find the genomic localization of the gene. Thus, the translation of proteins back to DNA/RNA is of particular interest, and is called reverse translation or back-translation.

The Genetic Code

In 1968 the Nobel Prize in Medicine was awarded to Robert W. Holley, Har Gobind Khorana and Marshall W. Nirenberg for their interpretation of the Genetic Code (<http://nobelprize.org/medicine/laureates/1968/>). The Genetic Code represents translations of all 64 different codons into 20 different amino acids. Therefore it is no problem to translate a DNA/RNA sequence into a specific protein. But due to the degeneracy of the genetic code, several codons may code for only one specific amino acid. This can be seen in the table below. After the discovery of the genetic code it has been concluded that different organism (and organelles) have genetic codes which are different from the "standard genetic code". Moreover, the amino acid alphabet is no longer limited to 20 amino acids. The 21st amino acid, selenocysteine, is encoded by an 'UGA' codon which is normally a stop codon. The discrimination of a selenocysteine over a stop codon is carried out by the translation machinery. Selenocysteines are very rare amino acids.

The table below shows the Standard Genetic Code which is the default translation table.

TTT F Phe	TCT S Ser	TAT Y Tyr	TGT C Cys
TTC F Phe	TCC S Ser	TAC Y Tyr	TGC C Cys
TTA L Leu	TCA S Ser	TAA * Ter	TGA * Ter
TTG L Leu i	TCG S Ser	TAG * Ter	TGG W Trp
CTT L Leu	CCT P Pro	CAT H His	CGT R Arg
CTC L Leu	CCC P Pro	CAC H His	CGC R Arg
CTA L Leu	CCA P Pro	CAA Q Gln	CGA R Arg
CTG L Leu i	CCG P Pro	CAG Q Gln	CGG R Arg
ATT I Ile	ACT T Thr	AAT N Asn	AGT S Ser
ATC I Ile	ACC T Thr	AAC N Asn	AGC S Ser
ATA I Ile	ACA T Thr	AAA K Lys	AGA R Arg
ATG M Met i	ACG T Thr	AAG K Lys	AGG R Arg
GTT V Val	GCT A Ala	GAT D Asp	GGT G Gly
GTC V Val	GCC A Ala	GAC D Asp	GGC G Gly
GTA V Val	GCA A Ala	GAA E Glu	GGA G Gly
GTG V Val	GCG A Ala	GAG E Glu	GGG G Gly

Challenge of reverse translation

A particular protein follows from the translation of a DNA sequence whereas the reverse translation need not have a specific solution according to the Genetic Code. The Genetic Code is degenerate which means that a particular amino acid can be translated into more than one codon. Hence there are ambiguities of the reverse translation.

Solving the ambiguities of reverse translation

In order to solve these ambiguities of reverse translation you can define how to prioritize the codon selection, e.g:

- Choose a codon randomly.
- Select the most frequent codon in a given organism.
- Randomize a codon, but with respect to its frequency in the organism.

As an example we want to translate an alanine to the corresponding codon. Four different codons can be used for this reverse translation; GCU, GCC, GCA or GCG. By picking either one by random choice we will get an alanine.

The most frequent codon, coding for an alanine in *E. coli* is GCG, encoding 33.7% of all alanines. Then comes GCC (25.5%), GCA (20.3%) and finally GCU (15.3%). The data are retrieved from the Codon usage database, see below. Always picking the most frequent codon does not necessarily give the best answer.

By selecting codons from a distribution of calculated codon frequencies, the DNA sequence obtained after the reverse translation, holds the correct (or nearly correct) codon distribution. It

should be kept in mind that the obtained DNA sequence is not necessarily identical to the original one encoding the protein in the first place, due to the degeneracy of the genetic code.

In order to obtain the best possible result of the reverse translation, one should use the codon frequency table from the correct organism or a closely related species. The codon usage of the mitochondrial chromosome are often different from the native chromosome(s), thus mitochondrial codon frequency tables should only be used when working specifically with mitochondria.

17.10 Proteolytic cleavage detection

CLC Main Workbench offers to analyze protein sequences with respect to cleavage by a selection of proteolytic enzymes. This section explains how to adjust the detection parameters and offers basic information on proteolytic cleavage in general.

17.10.1 Proteolytic cleavage parameters

Given a protein sequence, *CLC Main Workbench* detects proteolytic cleavage sites in accordance with detection parameters and shows the detected sites as annotations on the sequence and in textual format in a table below the sequence view.

Detection of proteolytic cleavage sites is initiated by:

**right-click a protein sequence in Navigation Area | Toolbox | Protein Analysis (📄)|
Proteolytic Cleavage, (✂️)**

This opens the dialog shown in figure 17.23:

Figure 17.23: Choosing sequence CAA32220 for proteolytic cleavage.

CLC Main Workbench allows you to detect proteolytic cleavages for several sequences at a time. Correct the list of sequences by selecting a sequence and clicking the arrows pointing left and right. Then click **Next** to go to **Step 2**.

In **Step 2** you can select proteolytic cleavage enzymes. The list of available enzymes will be expanded continuously. Presently, the list contains the enzymes shown in figure 17.24. The full list of enzymes and their cleavage patterns can be seen in Appendix, section E.

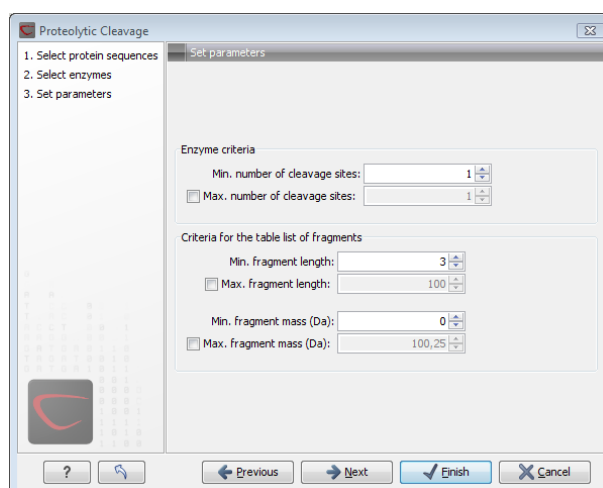

Figure 17.24: Setting parameters for proteolytic cleavage detection.

Select the enzymes you want to use for detection. When the relevant enzymes are chosen, click **Next**.

In **Step 3** you can set parameters for the detection. This limits the number of detected cleavages. Figure 17.25 shows an example of how parameters can be set.

- **Min. and max. number of cleavage sites.** Certain proteolytic enzymes cleave at many positions in the amino acid sequence. For instance proteinase K cleaves at nine different amino acids, regardless of the surrounding residues. Thus, it can be very useful to limit the number of actual cleavage sites before running the analysis.

Figure 17.25: Setting parameters for proteolytic cleavage detection.

- **Min. and max. fragment length** Likewise, it is possible to limit the output to only display sequence fragments between a chosen length. Both a lower and upper limit can be chosen.
- **Min. and max. fragment mass** The molecular weight is not necessarily directly correlated to the fragment length as amino acids have different molecular masses. For that reason it is also possible to limit the search for proteolytic cleavage sites to mass-range.

Example!: If you have one protein sequence but you only want to show which enzymes cut between two and four times. Then you should select "The enzymes has more cleavage sites than 2" and select "The enzyme has less cleavage sites than 4". In the next step you should simply select all enzymes. This will result in a view where only enzymes which cut 2,3 or 4 times are presented.

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

The result of the detection is displayed in figure 17.26.

Figure 17.26: The result of the proteolytic cleavage detection.

Depending on the settings in the program, the output of the proteolytic cleavage site detection will display two views on the screen. The top view shows the actual protein sequence with the predicted cleavage sites indicated by small arrows. If no labels are found on the arrows they can be enabled by setting the labels in the "annotation layout" in the preference panel. The bottom view shows a text output of the detection, listing the individual fragments and information on these.

17.10.2 Bioinformatics explained: Proteolytic cleavage

Proteolytic cleavage is basically the process of breaking the peptide bonds between amino acids in proteins. This process is carried out by enzymes called peptidases, proteases or proteolytic cleavage enzymes.

Proteins often undergo proteolytic processing by specific proteolytic enzymes (proteases/peptidases) before final maturation of the protein. Proteins can also be cleaved as a result of intracellular processing of, for example, misfolded proteins. Another example of proteolytic processing of proteins is secretory proteins or proteins targeted to organelles, which have their signal peptide removed by specific signal peptidases before release to the extracellular environment or specific organelle.

Below a few processes are listed where proteolytic enzymes act on a protein substrate.

- N-terminal methionine residues are often removed after translation.
- Signal peptides or targeting sequences are removed during translocation through a membrane.
- Viral proteins that were translated from a monocistronic mRNA are cleaved.
- Proteins or peptides can be cleaved and used as nutrients.
- Precursor proteins are often processed to yield the mature protein.

Proteolytic cleavage of proteins has shown its importance in laboratory experiments where it is often useful to work with specific peptide fragments instead of entire proteins.

Proteases also have commercial applications. As an example proteases can be used as detergents for cleavage of proteinaceous stains in clothing.

The general nomenclature of cleavage site positions of the substrate were formulated by Schechter and Berger, 1967-68 [Schechter and Berger, 1967], [Schechter and Berger, 1968]. They designate the cleavage site between P1-P1', incrementing the numbering in the N-terminal direction of the cleaved peptide bond (P2, P3, P4, etc..). On the carboxyl side of the cleavage site the numbering is incremented in the same way (P1', P2', P3' etc.). This is visualized in figure 17.27.

Proteases often have a specific recognition site where the peptide bond is cleaved. As an example trypsin only cleaves at lysine or arginine residues, but it does not matter (with a few exceptions) which amino acid is located at position P1'(carboxyterminal of the cleavage site). Another example is trombin which cleaves if an arginine is found in position P1, but not if a D or E is found in position P1' at the same time. (See figure 17.28).

Figure 17.27: Nomenclature of the peptide substrate. The substrate is cleaved between position P1-P1'.

Figure 17.28: Hydrolysis of the peptide bond between two amino acids. Trypsin cleaves unspecifically at lysine or arginine residues whereas trombin cleaves at arginines if aspartate or glutamate is absent.

Bioinformatics approaches are used to identify potential peptidase cleavage sites. Fragments can be found by scanning the amino acid sequence for patterns which match the corresponding cleavage site for the protease. When identifying cleaved fragments it is relatively important to know the calculated molecular weight and the isoelectric point.

18.11.2 Results - binding sites and fragments	365
18.12 Order primers	368

CLC Main Workbench offers graphically and algorithmically advanced design of primers and probes for various purposes. This chapter begins with a brief introduction to the general concepts of the primer designing process. Then follows instructions on how to adjust parameters for primers, how to inspect and interpret primer properties graphically and how to interpret, save and analyze the output of the primer design analysis. After a description of the different reaction types for which primers can be designed, the chapter closes with sections on how to match primers with other sequences and how to create a primer order.

18.1 Primer design - an introduction

Primer design can be accessed in two ways:

select sequence | Toolbox in the Menu Bar | Primers and Probes () | Design Primers () | OK

or **right-click sequence | Show | Primer ()**

In the primer view (see figure 18.1), the basic options for viewing the template sequence are the same as for the standard sequence view. See section 11.1 for an explanation of these options.

Note! This means that annotations such as e.g. known SNP's or exons can be displayed on the template sequence to guide the choice of primer regions. Also, traces in sequencing reads can be shown along with the structure to guide e.g. the re-sequencing of poorly resolved regions.

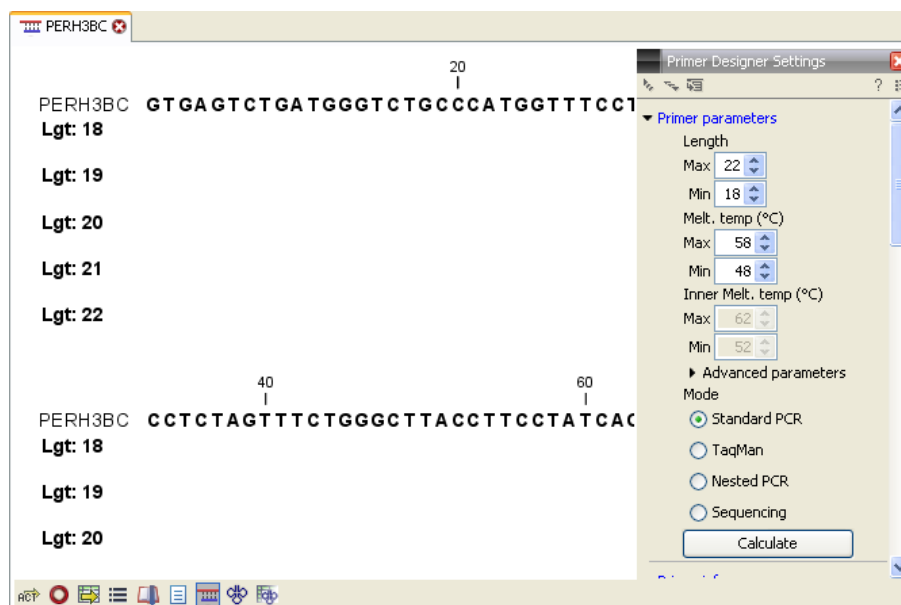

Figure 18.1: The initial view of the sequence used for primer design.

18.1.1 General concept

The concept of the primer view is that the user first chooses the desired reaction type for the session in the Primer Parameters preference group, e.g. *Standard PCR*. Reflecting the choice of reaction type, it is now possible to select one or more regions on the sequence and to use the right-click mouse menu to designate these as primer or probe regions (see figure 18.2).

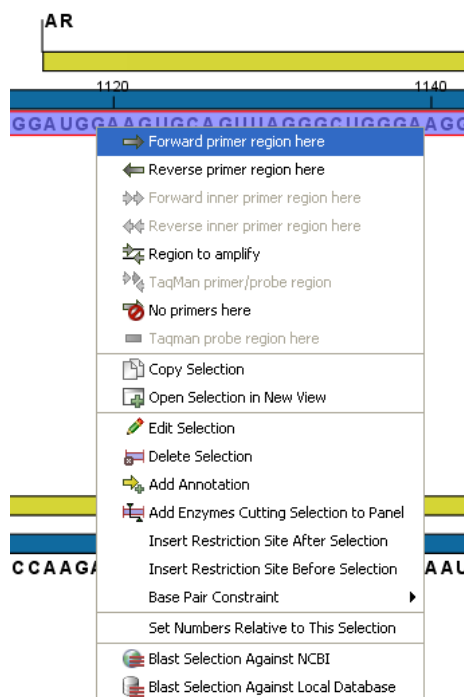

Figure 18.2: Right-click menu allowing you to specify regions for the primer design

When a region is chosen, graphical information about the properties of all possible primers in this region will appear in lines beneath it. By default, information is shown using a compact mode but the user can change to a more detailed mode in the Primer information preference group.

The number of information lines reflects the chosen length interval for primers and probes. In the compact information mode one line is shown for every possible primer-length and each of these lines contain information regarding all possible primers of the given length. At each potential primer starting position, a circular information point is shown which indicates whether the primer fulfills the requirements set in the primer parameters preference group. A green circle indicates a primer which fulfills all criteria and a red circle indicates a primer which fails to meet one or more of the set criteria. For more detailed information, place the mouse cursor over the circle representing the primer of interest. A tool-tip will then appear on screen, displaying detailed information about the primer in relation to the set criteria. To locate the primer on the sequence, simply left-click the circle using the mouse.

The various primer parameters can now be varied to explore their effect and the view area will dynamically update to reflect this allowing for a high degree of interactivity in the primer design process.

After having explored the potential primers the user may have found a satisfactory primer and choose to export this directly from the view area using a mouse right-click on the primers information point. This does not allow for any design information to enter concerning the properties of primer/probe pairs or sets e.g. primer pair annealing and T_m difference between primers. If the latter is desired the user can use the **Calculate** button at the bottom of the Primer parameter preference group. This will activate a dialog, the contents of which depends on the chosen mode. Here, the user can set primer-pair specific setting such as allowed or desired T_m

difference and view the single-primer parameters which were chosen in the Primer parameters preference group.

Upon pressing finish, an algorithm will generate all possible primer sets and rank these based on their characteristics and the chosen parameters. A list will appear displaying the 100 most high scoring sets and information pertaining to these. The search result can be saved to the navigator. From the result table, suggested primers or primer/probe sets can be explored since clicking an entry in the table will highlight the associated primers and probes on the sequence. It is also possible to save individual primers or sets from the table through the mouse right-click menu. For a given primer pair, the amplified PCR fragment can also be opened or saved using the mouse right-click menu.

18.1.2 Scoring primers

CLC Main Workbench employs a proprietary algorithm to rank primer and probe solutions. The algorithm considers both the parameters pertaining to single oligos, such as e.g. the secondary structure score and parameters pertaining to oligo-pairs such as e.g. the oligo pair-annealing score. The ideal score for a solution is 100 and solutions are thus ranked in descending order. Each parameter is assigned an ideal value and a tolerance. Consider for example oligo self-annealing, here the ideal value of the annealing score is 0 and the tolerance corresponds to the maximum value specified in the side panel. The contribution to the final score is determined by how much the parameter deviates from the ideal value and is scaled by the specified tolerance. Hence, a large deviation from the ideal and a small tolerance will give a large deduction in the final score and a small deviation from the ideal and a high tolerance will give a small deduction in the final score.

18.2 Setting parameters for primers and probes

The primer-specific view options and settings are found in the **Primer parameters** preference group in the **Side Panel** to the right of the view (see figure 18.3).

The image shows two side panels from a software interface. The left panel, titled 'Primer parameters', contains several settings: 'Length' with 'Max' at 22 and 'Min' at 18; 'Melt. temp (°C)' with 'Max' at 58 and 'Min' at 48; 'Inner Melt. temp (°C)' with 'Max' at 62 and 'Min' at 52. Below these are 'Advanced parameters' and 'Mode' options: 'Standard PCR' (selected), 'TaqMan', 'Nested PCR', and 'Sequencing'. A 'Calculate' button is at the bottom. The right panel, titled 'Primer information', has a 'Show' checkbox checked, and radio buttons for 'Compact' (selected) and 'Detailed'. Below are several unchecked checkboxes: 'G/C content(G/C)', 'Melting temp.(Tm)', 'Self annealing(SA)', 'Self end annealing(SEA)', 'Secondary structure(SS)', '3' end G/C', and '5' end G/C'.

Figure 18.3: The two groups of primer parameters (in the program, the Primer information group is listed below the other group).

18.2.1 Primer Parameters

In this preference group a number of criteria can be set, which the selected primers must meet. All the criteria concern *single primers*, as primer pairs are not generated until the **Calculate** button is pressed. Parameters regarding primer and probe sets are described in detail for each reaction mode (see below).

- **Length.** Determines the length interval within which primers can be designed by setting a maximum and a minimum length. The upper and lower lengths allowed by the program are 50 and 10 nucleotides respectively.
- **Melting temperature.** Determines the temperature interval within which primers must lie. When the *Nested PCR* or *TaqMan* reaction type is chosen, the first pair of melting temperature interval settings relate to the outer primer pair i.e. not the probe. Melting temperatures are calculated by a nearest-neighbor model which considers stacking interactions between neighboring bases in the primer-template complex. The model uses state-of-the-art thermodynamic parameters [SantaLucia, 1998] and considers the important contribution from the dangling ends that are present when a short primer anneals to a template sequence [Bommarito et al., 2000]. A number of parameters can be adjusted concerning the reaction mixture and which influence melting temperatures (see below). Melting temperatures are corrected for the presence of monovalent cations using the model of [SantaLucia, 1998] and temperatures are further corrected for the presence of magnesium, deoxynucleotide triphosphates (dNTP) and dimethyl sulfoxide (DMSO) using the model of [von Ahsen et al., 2001].
- **Inner melting temperature.** This option is only activated when the *Nested PCR* or *TaqMan* mode is selected. In *Nested PCR* mode, it determines the allowed melting temperature interval for the inner/nested pair of primers, and in *TaqMan* mode it determines the allowed temperature interval for the TaqMan probe.
- **Advanced parameters.** A number of less commonly used options
 - **Buffer properties.** A number of parameters concerning the reaction mixture which influence melting temperatures.
 - * **Primer concentration.** Specifies the concentration of primers and probes in units of nanomoles (nM)
 - * **Salt concentration.** Specifies the concentration of monovalent cations ($[NA^+]$, $[K^+]$ and equivalents) in units of millimoles (mM)
 - * **Magnesium concentration.** Specifies the concentration of magnesium cations ($[Mg^{++}]$) in units of millimoles (mM)
 - * **dNTP concentration.** Specifies the combined concentration of all deoxynucleotide triphosphates in units of millimoles (mM)
 - * **DMSO concentration.** Specifies the concentration of dimethyl sulfoxide in units of volume percent ($vol.\%$)
 - **GC content.** Determines the interval of GC content (% C and G nucleotides in the primer) within which primers must lie by setting a maximum and a minimum GC content.
 - **Self annealing.** Determines the maximum self annealing value of all primers and probes. This determines the amount of base-pairing allowed between two copies of

the same molecule. The self annealing score is measured in number of hydrogen bonds between two copies of primer molecules, with A-T base pairs contributing 2 hydrogen bonds and G-C base pairs contributing 3 hydrogen bonds.

- **Self end annealing.** Determines the maximum self end annealing value of all primers and probes. This determines the number of consecutive base pairs allowed between the 3' end of one primer and another copy of that primer. This score is calculated in number of hydrogen bonds (the example below has a score of 4 - derived from 2 A-T base pairs each with 2 hydrogen bonds).

```
AATTCCCTACAATCCCCAAA
      ||
      AAACCCCTAACATCCCTTAA
```

- **Secondary structure.** Determines the maximum score of the optimal secondary DNA structure found for a primer or probe. Secondary structures are scored by the number of hydrogen bonds in the structure, and 2 extra hydrogen bonds are added for each stacking base-pair in the structure.
- **3' end G/C restrictions.** When this checkbox is selected it is possible to specify restrictions concerning the number of G and C molecules in the 3' end of primers and probes. A low G/C content of the primer/probe 3' end increases the specificity of the reaction. A high G/C content facilitates a tight binding of the oligo to the template but also increases the possibility of mispriming. Unfolding the preference groups yields the following options:
 - **End length.** The number of consecutive terminal nucleotides for which to consider the C/G content
 - **Max no. of G/C.** The maximum number of G and C nucleotides allowed within the specified length interval
 - **Min no. of G/C.** The minimum number of G and C nucleotides required within the specified length interval
- **5' end G/C restrictions.** When this checkbox is selected it is possible to specify restrictions concerning the number of G and C molecules in the 5' end of primers and probes. A high G/C content facilitates a tight binding of the oligo to the template but also increases the possibility of mis-priming. Unfolding the preference groups yields the same options as described above for the 3' end.
- **Mode.** Specifies the reaction type for which primers are designed:
 - **Standard PCR.** Used when the objective is to design primers, or primer pairs, for PCR amplification of a single DNA fragment.
 - **Nested PCR.** Used when the objective is to design two primer pairs for nested PCR amplification of a single DNA fragment.
 - **Sequencing.** Used when the objective is to design primers for DNA sequencing.
 - **TaqMan.** Used when the objective is to design a primer pair and a probe for TaqMan quantitative PCR.

Each mode is described further below.

- **Calculate.** Pushing this button will activate the algorithm for designing primers

18.3 Graphical display of primer information

The primer information settings are found in the **Primer information** preference group in the **Side Panel** to the right of the view (see figure 18.3).

There are two different ways to display the information relating to a single primer, the detailed and the compact view. Both are shown below the primer regions selected on the sequence.

18.3.1 Compact information mode

This mode offers a condensed overview of all the primers that are available in the selected region. When a region is chosen primer information will appear in lines beneath it (see figure 18.4).

Figure 18.4: Compact information mode

The number of information lines reflects the chosen length interval for primers and probes. One line is shown for every possible primer-length, if the length interval is widened more lines will appear. At each potential primer starting position a circle is shown which indicates whether the primer fulfills the requirements set in the primer parameters preference group. A green primer indicates a primer which fulfills all criteria and a red primer indicates a primer which fails to meet one or more of the set criteria. For more detailed information, place the mouse cursor over the circle representing the primer of interest. A tool-tip will then appear on screen displaying detailed information about the primer in relation to the set criteria. To locate the primer on the sequence, simply left-click the circle using the mouse.

The various primer parameters can now be varied to explore their effect and the view area will dynamically update to reflect this. If e.g. the allowed melting temperature interval is widened more green circles will appear indicating that more primers now fulfill the set requirements and if e.g. a requirement for 3' G/C content is selected, red circles will appear at the starting points of the primers which fail to meet this requirement.

18.3.2 Detailed information mode

In this mode a very detailed account is given of the properties of all the available primers. When a region is chosen primer information will appear in groups of lines beneath it (see figure 18.5).

Figure 18.5: Detailed information mode

The number of information-line-groups reflects the chosen length interval for primers and probes. One group is shown for every possible primer length. Within each group, a line is shown for every primer property that is selected from the checkboxes in the primer information preference group. Primer properties are shown at each potential primer starting position and are of two types:

Properties with numerical values are represented by bar plots. A green bar represents the starting point of a primer that meets the set requirement and a red bar represents the starting point of a primer that fails to meet the set requirement:

- G/C content
- Melting temperature
- Self annealing score
- Self end annealing score
- Secondary structure score

Properties with Yes - No values. If a primer meets the set requirement a green circle will be shown at its starting position and if it fails to meet the requirement a red dot is shown at its starting position:

- C/G at 3' end
- C/G at 5' end

Common to both sorts of properties is that mouse clicking an information point (filled circle or bar) will cause the region covered by the associated primer to be selected on the sequence.

18.4 Output from primer design

The output generated by the primer design algorithm is a table of proposed primers or primer pairs with the accompanying information (see figure 18.6).

Score	Pair annealing align (Fwd,Rev)	Fragment length...	Sequence Fwd	Melt. temp. Fwd	Sequence Rev	Melt. temp. Rev
62,56	GGTGGGAGGCTCTATATAA AAGGAGATAAAGAGTCAAGG	598,00	GGTGGGAGGCTCTATATAA	48,572	GGAAGTGAAGATAGAGGAA	49,094
57,873	GGTGGGAGGCTCTATATAA AGGAGATAAAGAGTCAAGG	598,00	GGTGGGAGGCTCTATATAA	48,572	GGAAGTGAAGATAGAGGA	49,566
55,921	GCCTGGATAGCGGTTTGA AGAAGTACTTGGTCGGAG	660,00	GCCTGGATAGCGGTTTGA	56,978	GAGGCTGTTGATGAAGA	56,439

Figure 18.6: Proposed primers

In the preference panel of the table, it is possible to customize which columns are shown in the table. See the sections below on the different reaction types for a description of the available information.

The columns in the output table can be sorted by the present information. For example the user can choose to sort the available primers by their score (default) or by their self annealing score, simply by right-clicking the column header.

The output table interacts with the accompanying primer editor such that when a proposed combination of primers and probes is selected in the table the primers and probes in this solution are highlighted on the sequence.

18.4.1 Saving primers

Primer solutions in a table row can be saved by selecting the row and using the right-click mouse menu. This opens a dialog that allows the user to save the primers to the desired location. Primers and probes are saved as DNA sequences in the program. This means that all available DNA analyzes can be performed on the saved primers, including BLAST. Furthermore, the primers can be edited using the standard sequence view to introduce e.g. mutations and restriction sites.

18.4.2 Saving PCR fragments

The PCR fragment generated from the primer pair in a given table row can also be saved by selecting the row and using the right-click mouse menu. This opens a dialog that allows the user to save the fragment to the desired location. The fragment is saved as a DNA sequence and the position of the primers is added as annotation on the sequence. The fragment can then be used for further analysis and included in e.g. an in-silico cloning experiment using the cloning editor.

18.4.3 Adding primer binding annotation

You can add an annotation to the template sequence specifying the binding site of the primer: Right-click the primer in the table and select **Mark primer annotation on sequence**.

18.5 Standard PCR

This mode is used to design primers for a PCR amplification of a single DNA fragment.

18.5.1 User input

In this mode the user must define either a *Forward primer region*, a *Reverse primer region*, or both. These are defined by making a selection on the sequence and right-clicking the selection. It is also possible to define a *Region to amplify* in which case a forward- and a reverse primer region are automatically placed so as to ensure that the designated region will be included in the PCR fragment. If areas are known where primers must not bind (e.g. repeat rich areas), one or more *No primers here* regions can be defined.

If two regions are defined, it is required that at least a part of the *Forward primer region* is located upstream of the *Reverse primer region*.

After exploring the available primers (see section 18.3) and setting the desired parameter values in the Primer Parameters preference group, the **Calculate** button will activate the primer design algorithm.

When a single primer region is defined

If only a single region is defined, only *single primers* will be suggested by the algorithm.

After pressing the **Calculate** button a dialog will appear (see figure 18.7).

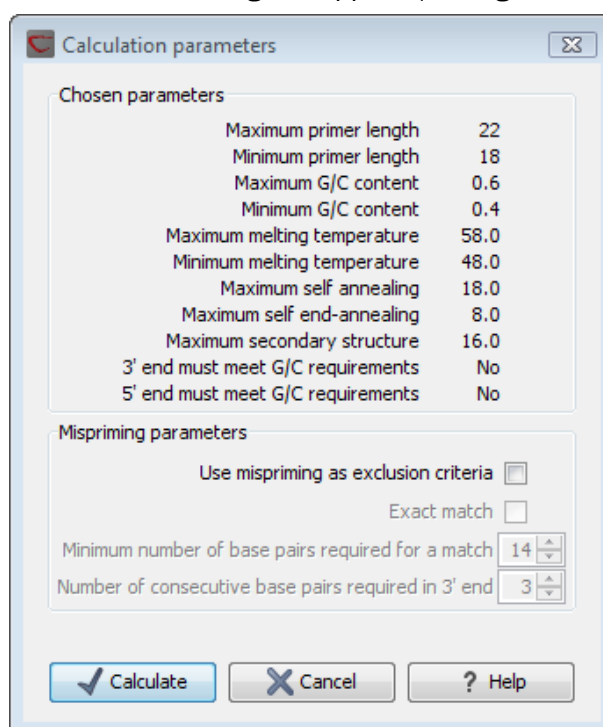

Figure 18.7: Calculation dialog for PCR primers when only a single primer region has been defined.

The top part of this dialog shows the parameter settings chosen in the Primer parameters preference group which will be used by the design algorithm.

The lower part contains a menu where the user can choose to include mispriming as a criteria in the design process. If this option is selected the algorithm will search for competing binding sites of the primer within the sequence.

The adjustable parameters for the search are:

- **Exact match.** Choose only to consider exact matches of the primer, i.e. all positions must base pair with the template for mispriming to occur.
- **Minimum number of base pairs required for a match.** How many nucleotides of the primer that must base pair to the sequence in order to cause mispriming.
- **Number of consecutive base pairs required in 3' end.** How many consecutive 3' end base pairs in the primer that **MUST** be present for mispriming to occur. This option is included since 3' terminal base pairs are known to be essential for priming to occur.

Note! Including a search for potential mispriming sites will prolong the search time substantially if long sequences are used as template and if the minimum number of base pairs required for a match is low. If the region to be amplified is part of a very long molecule and mispriming is a concern, consider extracting part of the sequence prior to designing primers.

When both forward and reverse regions are defined

If both a forward and a reverse region are defined, *primer pairs* will be suggested by the algorithm.

After pressing the **Calculate** button a dialog will appear (see figure 18.8).

Chosen parameters	
Maximum primer length	22
Minimum primer length	18
Maximum G/C content	0.6
Minimum G/C content	0.4
Maximum melting temperature	58.0
Minimum melting temperature	48.0
Maximum self annealing	18.0
Maximum self end-annealing	8.0
Maximum secondary structure	16.0
3' end must meet G/C requirements	No
5' end must meet G/C requirements	No

Primer combination parameters	
Max percentage point difference in G/C content	35
Max difference in melting temperatures within a primer pair	5
Max hydrogen bonds between pairs	18
Max hydrogen bonds between pair ends	8
Maximum length of amplicon	2.000

Mispriming parameters	
Use mispriming as exclusion criteria	<input type="checkbox"/>
Exact match	<input type="checkbox"/>
Minimum number of base pairs required for a match	14
Number of consecutive base pairs required in 3' end	3

Buttons: Calculate, Cancel, Help

Figure 18.8: Calculation dialog for PCR primers when two primer regions have been defined.

Again, the top part of this dialog shows the parameter settings chosen in the Primer parameters preference group which will be used by the design algorithm. The lower part again contains a menu where the user can choose to include mispriming of both primers as a criteria in the design process (see above). The central part of the dialog contains parameters pertaining to primer pairs. Here three parameters can be set:

- Maximum percentage point difference in G/C content - if this is set at e.g. 5 points a pair of primers with 45% and 49% G/C nucleotides, respectively, will be allowed, whereas a pair of primers with 45% and 51% G/C nucleotides, respectively will not be included.
- Maximal difference in melting temperature of primers in a pair - the number of degrees Celsius that primers in a pair are all allowed to differ.
- Max hydrogen bonds between pairs - the maximum number of hydrogen bonds allowed between the forward and the reverse primer in a primer pair.
- Max hydrogen bonds between pair ends - the maximum number of hydrogen bonds allowed in the consecutive ends of the forward and the reverse primer in a primer pair.
- Maximum length of amplicon - determines the maximum length of the PCR fragment.

18.5.2 Standard PCR output table

If only a single region is selected the following columns of information are available:

- Sequence - the primer's sequence.
- Score - measures how much the properties of the primer (or primer pair) deviates from the optimal solution in terms of the chosen parameters and tolerances. The higher the score, the better the solution. The scale is from 0 to 100.
- Region - the interval of the template sequence covered by the primer
- Self annealing - the maximum self annealing score of the primer in units of hydrogen bonds
- Self annealing alignment - a visualization of the highest maximum scoring self annealing alignment
- Self end annealing - the maximum score of consecutive end base-pairings allowed between the ends of two copies of the same molecule in units of hydrogen bonds
- GC content - the fraction of G and C nucleotides in the primer
- Melting temperature of the primer-template complex
- Secondary structure score - the score of the optimal secondary DNA structure found for the primer. Secondary structures are scored by adding the number of hydrogen bonds in the structure, and 2 extra hydrogen bonds are added for each stacking base-pair in the structure
- Secondary structure - a visualization of the optimal DNA structure found for the primer

If both a forward and a reverse region are selected a table of primer pairs is shown, where the above columns (excluding the score) are represented twice, once for the forward primer (designated by the letter F) and once for the reverse primer (designated by the letter R).

Before these, and following the score of the primer pair, are the following columns pertaining to primer pair-information available:

- Pair annealing - the number of hydrogen bonds found in the optimal alignment of the forward and the reverse primer in a primer pair
- Pair annealing alignment - a visualization of the optimal alignment of the forward and the reverse primer in a primer pair.
- Pair end annealing - the maximum score of consecutive end base-pairings found between the ends of the two primers in the primer pair, in units of hydrogen bonds
- Fragment length - the length (number of nucleotides) of the PCR fragment generated by the primer pair

18.6 Nested PCR

Nested PCR is a modification of Standard PCR, aimed at reducing product contamination due to the amplification of unintended primer binding sites (mispriming). If the intended fragment can not be amplified without interference from competing binding sites, the idea is to seek out a larger outer fragment which can be unambiguously amplified and which contains the smaller intended fragment. Having amplified the outer fragment to large numbers, the PCR amplification of the inner fragment can proceed and will yield amplification of this with minimal contamination.

Primer design for nested PCR thus involves designing two primer pairs, one for the outer fragment and one for the inner fragment.

In *Nested PCR* mode the user must thus define four regions a *Forward primer region* (the outer forward primer), a *Reverse primer region* (the outer reverse primer), a *Forward inner primer region*, and a *Reverse inner primer region*. These are defined by making a selection on the sequence and right-clicking the selection. If areas are known where primers must not bind (e.g. repeat rich areas), one or more *No primers here* regions can be defined.

It is required that the *Forward primer region*, is located upstream of the *Forward inner primer region*, that the *Forward inner primer region*, is located upstream of the *Reverse inner primer region*, and that the *Reverse inner primer region*, is located upstream of the *Reverse primer region*.

In *Nested PCR* mode the *Inner melting temperature* menu in the Primer parameters panel is activated, allowing the user to set a separate melting temperature interval for the inner and outer primer pairs.

After exploring the available primers (see section 18.3) and setting the desired parameter values in the Primer parameters preference group, the **Calculate** button will activate the primer design algorithm.

After pressing the **Calculate** button a dialog will appear (see figure 18.9).

The top and bottom parts of this dialog are identical to the *Standard PCR* dialog for designing primer pairs described above.

The central part of the dialog contains parameters pertaining to primer pairs and the comparison between the outer and the inner pair. Here five options can be set:

- Maximum percentage point difference in G/C content (described above under Standard PCR) - this criteria is applied to both primer pairs independently.

Figure 18.9: Calculation dialog

- Maximal difference in melting temperature of primers in a pair - the number of degrees Celsius that primers in a pair are all allowed to differ. This criteria is applied to both primer pairs independently.
- Maximum pair annealing score - the maximum number of hydrogen bonds allowed between the forward and the reverse primer in a primer pair. This criteria is applied to all possible combinations of primers.
- Minimum difference in the melting temperature of primers in the inner and outer primer pair - all comparisons between the melting temperature of primers from the two pairs must be at least this different, otherwise the primer set is excluded. This option is applied to ensure that the inner and outer PCR reactions can be initiated at different annealing temperatures. Please note that to ensure flexibility there is no directionality indicated when setting parameters for melting temperature differences between inner and outer primer pair, i.e. it is not specified whether the inner pair should have a lower or higher T_m . Instead this is determined by the allowed temperature intervals for inner and outer primers that are set in the primer parameters preference group in the side panel. If a higher T_m of inner primers is desired, choose a T_m interval for inner primers which has higher values than the interval for outer primers.
- Two radio buttons allowing the user to choose between a fast and an accurate algorithm for primer prediction.

18.6.1 Nested PCR output table

In nested PCR there are four primers in a solution, forward outer primer (FO), forward inner primer (FI), reverse inner primer (RI) and a reverse outer primer (RO).

The output table can show primer-pair combination parameters for all four combinations of primers and single primer parameters for all four primers in a solution (see section on Standard PCR for an explanation of the available primer-pair and single primer information).

The fragment length in this mode refers to the length of the PCR fragment generated by the inner primer pair, and this is also the PCR fragment which can be exported.

18.7 TaqMan

CLC Main Workbench allows the user to design primers and probes for TaqMan PCR applications.

TaqMan probes are oligonucleotides that contain a fluorescent reporter dye at the 5' end and a quenching dye at the 3' end. Fluorescent molecules become excited when they are irradiated and usually emit light. However, in a TaqMan probe the energy from the fluorescent dye is transferred to the quencher dye by fluorescence resonance energy transfer as long as the quencher and the dye are located in close proximity i.e. when the probe is intact. TaqMan probes are designed to anneal within a PCR product amplified by a standard PCR primer pair. If a TaqMan probe is bound to a product template, the replication of this will cause the Taq polymerase to encounter the probe. Upon doing so, the 5' exonuclease activity of the polymerase will cleave the probe. This cleavage separates the quencher and the dye, and as a result the reporter dye starts to emit fluorescence.

The TaqMan technology is used in Real-Time quantitative PCR. Since the accumulation of fluorescence mirrors the accumulation of PCR products it can be monitored in real-time and used to quantify the amount of template initially present in the buffer.

The technology is also used to detect genetic variation such as SNP's. By designing a TaqMan probe which will specifically bind to one of two or more genetic variants it is possible to detect genetic variants by the presence or absence of fluorescence in the reaction.

A specific requirement of TaqMan probes is that a G nucleotide can not be present at the 5' end since this will quench the fluorescence of the reporter dye. It is recommended that the melting temperature of the TaqMan probe is about 10 degrees celsius higher than that of the primer pair.

Primer design for TaqMan technology involves designing a primer pair and a TaqMan probe.

In *TaqMan* the user must thus define three regions: a *Forward primer region*, a *Reverse primer region*, and a *TaqMan probe region*. The easiest way to do this is to designate a *TaqMan primer/probe region* spanning the sequence region where TaqMan amplification is desired. This will automatically add all three regions to the sequence. If more control is desired about the placing of primers and probes the *Forward primer region*, *Reverse primer region* and *TaqMan probe region* can all be defined manually. If areas are known where primers or probes must not bind (e.g. repeat rich areas), one or more *No primers here* regions can be defined. The regions are defined by making a selection on the sequence and right-clicking the selection.

It is required that at least a part of the *Forward primer region* is located upstream of the *TaqMan Probe region*, and that the *TaqMan Probe region*, is located upstream of a part of the *Reverse primer region*.

In *TaqMan* mode the *Inner melting temperature* menu in the primer parameters panel is activated allowing the user to set a separate melting temperature interval for the TaqMan probe.

After exploring the available primers (see section 18.3) and setting the desired parameter values in the Primer Parameters preference group, the **Calculate** button will activate the primer design algorithm.

After pressing the **Calculate** button a dialog will appear (see figure 18.10) which is similar to the *Nested PCR* dialog described above (see section 18.6).

Chosen parameters	
Maximum primer length	22
Minimum primer length	18
Maximum G/C content	0.6
Minimum G/C content	0.4
Maximum melting temperature	58.0
Minimum melting temperature	48.0
Maximum self annealing	18.0
Maximum self end-annealing	8.0
Maximum secondary structure	16.0
3' end must meet G/C requirements	No
5' end must meet G/C requirements	No

Primer combination parameters	
Max percentage point difference in G/C content	35
Max difference in melting temperatures within a primer pair	5
Max hydrogen bonds between pairs	18
Max hydrogen bonds between pair ends	8
Minimum difference in melting temperature Inner-Outer	5
Maximum length of amplicon	300

Mispriming parameters	
Use mispriming as exclusion criteria	<input type="checkbox"/>
Exact match	<input type="checkbox"/>
Minimum number of base pairs required for a match	12
Number of consecutive base pairs required in 3' end	3

Figure 18.10: Calculation dialog

In this dialog the options to set a minimum and a desired melting temperature difference between outer and inner refers to primer pair and probe respectively.

Furthermore, the central part of the dialog contains an additional parameter

- Maximum length of amplicon - determines the maximum length of the PCR fragment generated in the TaqMan analysis.

18.7.1 TaqMan output table

In TaqMan mode there are two primers and a probe in a given solution, forward primer (F), reverse primer (R) and a TaqMan probe (TP).

The output table can show primer/probe-pair combination parameters for all three combinations of primers and single primer parameters for both primers and the TaqMan probe (see section on

Standard PCR for an explanation of the available primer-pair and single primer information).

The fragment length in this mode refers to the length of the PCR fragment generated by the primer pair, and this is also the PCR fragment which can be exported.

18.8 Sequencing primers

This mode is used to design primers for DNA sequencing.

In this mode the user can define a number of *Forward primer regions* and *Reverse primer regions* where a sequencing primer can start. These are defined by making a selection on the sequence and right-clicking the selection. If areas are known where primers must not bind (e.g. repeat rich areas), one or more *No primers here* regions can be defined.

No requirements are instated on the relative position of the regions defined.

After exploring the available primers (see section 18.3) and setting the desired parameter values in the Primer Parameters preference group, the **Calculate** button will activate the primer design algorithm.

After pressing the **Calculate** button a dialog will appear (see figure 18.11).

Figure 18.11: Calculation dialog for sequencing primers

Since design of sequencing primers does not require the consideration of interactions between primer pairs, this dialog is identical to the dialog shown in *Standard PCR* mode when only a single primer region is chosen. See the section 18.5 for a description.

18.8.1 Sequencing primers output table

In this mode primers are predicted independently for each region, but the optimal solutions are all presented in one table. The solutions are numbered consecutively according to their position on the sequence such that the forward primer region closest to the 5' end of the molecule is designated F1, the next one F2 etc.

For each solution, the single primer information described under Standard PCR is available in the table.

18.9 Alignment-based primer and probe design

CLC Main Workbench allows the user to design PCR primers and TaqMan probes based on an alignment of multiple sequences.

The primer designer for alignments can be accessed in two ways:

select alignment | Toolbox | Primers and Probes (📁) | Design Primers (🇺🇸) | OK

or **If the alignment is already open: | Click Primer Designer (🇺🇸) at the lower left part of the view**

In the alignment primer view (see figure 18.12), the basic options for viewing the template alignment are the same as for the standard view of alignments. See section 22 for an explanation of these options.

Note! This means that annotations such as e.g. known SNP's or exons can be displayed on the template sequence to guide the choice of primer regions. Since the definition of groups of sequences is essential to the primer design the selection boxes of the standard view are shown as default in the alignment primer view.

The screenshot displays the 'Primer Designer' window in CLC Main Workbench. The main area shows an alignment of three sequences: PERH2BD, PERH3BC, and a Consensus. Below each sequence is a 'Sequence logo' visualization. The primer designer settings panel on the right is open, showing the following parameters:

- Length:** Max: 22, Min: 18
- Melt temp (°C):** Max: 58, Min: 48
- Inner Melt temp (°C):** Max: 62, Min: 52
- Advanced parameters:** Mode: Standard PCR (selected), TaqMan (unselected)
- Primer solution:** Perfect match (selected), Allow degeneracy (unselected)
- Max:** 2

Figure 18.12: The initial view of an alignment used for primer design.

18.9.1 Specific options for alignment-based primer and probe design

Compared to the primer view of a single sequence the most notable difference is that the alignment primer view has no available graphical information. Furthermore, the selection boxes found to the left of the names in the alignment play an important role in specifying the oligo design process. This is elaborated below. The **Primer Parameters** group in the **Side Panel** has the same options for specifying primer requirements, but differs by the following (see figure 18.12):

- In the **Mode** submenu which specifies the reaction types the following options are found:
 - **Standard PCR.** Used when the objective is to design primers, or primer pairs, for PCR amplification of a single DNA fragment.
 - **TaqMan.** Used when the objective is to design a primer pair and a probe set for TaqMan quantitative PCR.
- The **Primer solution** submenu is used to specify requirements for the match of a PCR primer against the template sequences. These options are described further below. It contains the following options:
 - **Perfect match.**
 - **Allow degeneracy.**
 - **Allow mismatches.**

The work flow when designing alignment based primers and probes is as follows:

- Use selection boxes to specify groups of included and excluded sequences. To select all the sequences in the alignment, right-click one of the selection boxes and choose **Mark All**.
- Mark either a single forward primer region, a single reverse primer region or both on the sequence (and perhaps also a TaqMan region). Selections must cover all sequences in the included group. You can also specify that there should be no primers in a region (No Primers Here) or that a whole region should be amplified (Region to Amplify).
- Adjust parameters regarding single primers in the preference panel.
- Click the **Calculate** button.

18.9.2 Alignment based design of PCR primers

In this mode, a single or a pair of PCR primers are designed. *CLC Main Workbench* allows the user to design primers which will specifically amplify a group of *included* sequences but **not** amplify the remainder of the sequences, the *excluded* sequences. The selection boxes are used to indicate the status of a sequence, if the box is checked the sequence belongs to the included sequences, if not, it belongs to the excluded sequences. To design primers that are general for all primers in an alignment, simply add them all to the set of included sequences by checking all selection boxes. Specificity of priming is determined by criteria set by the user in the dialog box which is shown when the **Calculate** button is pressed (see below).

Different options can be chosen concerning the match of the primer to the template sequences in the included group:

- **Perfect match.** Specifies that the designed primers must have a perfect match to all relevant sequences in the alignment. When selected, primers will thus only be located in regions that are completely conserved within the sequences belonging to the included group.
- **Allow degeneracy.** Designs primers that may include ambiguity characters where heterogeneities occur in the included template sequences. The allowed fold of degeneracy is user defined and corresponds to the number of possible primer combinations formed by a degenerate primer. Thus, if a primer covers two 4-fold degenerate site and one 2-fold degenerate site the total fold of degeneracy is $4 * 4 * 2 = 32$ and the primer will, when supplied from the manufacturer, consist of a mixture of 32 different oligonucleotides. When scoring the available primers, degenerate primers are given a score which decreases with the fold of degeneracy.
- **Allow mismatches.** Designs primers which are allowed a specified number of mismatches to the included template sequences. The melting temperature algorithm employed includes the latest thermodynamic parameters for calculating T_m when single-base mismatches occur.

When in Standard PCR mode, clicking the **Calculate** button will prompt the dialog shown in figure 18.13.

The top part of this dialog shows the single-primer parameter settings chosen in the Primer parameters preference group which will be used by the design algorithm.

The central part of the dialog contains parameters pertaining to primer specificity (this is omitted if all sequences belong to the included group). Here, three parameters can be set:

- Minimum number of mismatches - the minimum number of mismatches that a primer must have against all sequences in the excluded group to ensure that it does not prime these.
- Minimum number of mismatches in 3' end - the minimum number of mismatches that a primer must have in its 3' end against all sequences in the excluded group to ensure that it does not prime these.
- Length of 3' end - the number of consecutive nucleotides to consider for mismatches in the 3' end of the primer.

The lower part of the dialog contains parameters pertaining to primer pairs (this is omitted when only designing a single primer). Here, three parameters can be set:

- Maximum percentage point difference in G/C content - if this is set at e.g. 5 points a pair of primers with 45% and 49% G/C nucleotides, respectively, will be allowed, whereas a pair of primers with 45% and 51% G/C nucleotides, respectively will not be included.
- Maximal difference in melting temperature of primers in a pair - the number of degrees Celsius that primers in a pair are all allowed to differ.
- Max hydrogen bonds between pairs - the maximum number of hydrogen bonds allowed between the forward and the reverse primer in a primer pair.
- Maximum length of amplicon - determines the maximum length of the PCR fragment.

The output of the design process is a table of single primers or primer pairs as described for primer design based on single sequences. These primers are specific to the included sequences in the alignment according to the criteria defined for specificity. The only novelty in the table, is that melting temperatures are displayed with both a maximum, a minimum and an average value to reflect that degenerate primers or primers with mismatches may have heterogeneous behavior on the different templates in the group of included sequences.

Figure 18.13: Calculation dialog shown when designing alignment based PCR primers.

18.9.3 Alignment-based TaqMan probe design

CLC Main Workbench allows the user to design solutions for TaqMan quantitative PCR which consist of four oligos: a general primer pair which will amplify all sequences in the alignment, a specific TaqMan probe which will match the group of *included* sequences but **not** match the *excluded* sequences and a specific TaqMan probe which will match the group of *excluded* sequences but **not** match the *included* sequences. As above, the selection boxes are used to indicate the status of a sequence, if the box is checked the sequence belongs to the included sequences, if not, it belongs to the excluded sequences. We use the terms included and excluded here to be consistent with the section above although a probe solution is presented for both groups. In TaqMan mode, primers are not allowed degeneracy or mismatches to any template sequence in the alignment, variation is only allowed/required in the TaqMan probes.

Pushing the **Calculate** button will cause the dialog shown in figure 18.14 to appear.

The top part of this dialog is identical to the *Standard PCR* dialog for designing primer pairs described above.

The central part of the dialog contains parameters to define the specificity of TaqMan probes. Two parameters can be set:

- Minimum number of mismatches - the minimum total number of mismatches that must

exist between a specific TaqMan probe and all sequences which belong to the group not recognized by the probe.

- Minimum number of mismatches in central part - the minimum number of mismatches in the central part of the oligo that must exist between a specific TaqMan probe and all sequences which belong to the group not recognized by the probe.

The lower part of the dialog contains parameters pertaining to primer pairs and the comparison between the outer oligos (primers) and the inner oligos (TaqMan probes). Here, five options can be set:

- Maximum percentage point difference in G/C content (described above under Standard PCR).
- Maximal difference in melting temperature of primers in a pair - the number of degrees Celsius that primers in the primer pair are all allowed to differ.
- Maximum pair annealing score - the maximum number of hydrogen bonds allowed between the forward and the reverse primer in an oligo pair. This criteria is applied to all possible combinations of primers and probes.
- Minimum difference in the melting temperature of primer (outer) and TaqMan probe (inner) oligos - all comparisons between the melting temperature of primers and probes must be at least this different, otherwise the solution set is excluded.
- Desired temperature difference in melting temperature between outer (primers) and inner (TaqMan) oligos - the scoring function discounts solution sets which deviate greatly from this value. Regarding this, and the minimum difference option mentioned above, please note that to ensure flexibility there is no directionality indicated when setting parameters for melting temperature differences between probes and primers, i.e. it is not specified whether the probes should have a lower or higher T_m . Instead this is determined by the allowed temperature intervals for inner and outer oligos that are set in the primer parameters preference group in the side panel. If a higher T_m of probes is required, choose a T_m interval for probes which has higher values than the interval for outer primers.

The output of the design process is a table of solution sets. Each solution set contains the following: a set of primers which are general to all sequences in the alignment, a TaqMan probe which is specific to the set of included sequences (sequences where selection boxes are checked) and a TaqMan probe which is specific to the set of excluded sequences (marked by *). Otherwise, the table is similar to that described above for TaqMan probe prediction on single sequences.

18.10 Analyze primer properties

CLC Main Workbench can calculate and display the properties of predefined primers and probes:

select a primer sequence (primers are represented as DNA sequences in the Navigation Area) | Toolbox in the Menu Bar | Primers and Probes (📁) | Analyze Primer Properties (🔍)

Figure 18.14: Calculation dialog shown when designing alignment based TaqMan probes.

If a sequence was selected before choosing the Toolbox action, this sequence is now listed in the **Selected Elements** window of the dialog. Use the arrows to add or remove a sequence from the selected elements.

Clicking **Next** generates the dialog seen in figure 18.15:

Figure 18.15: The parameters for analyzing primer properties.

In the *Concentrations* panel a number of parameters can be specified concerning the reaction mixture and which influence melting temperatures

- **Primer concentration.** Specifies the concentration of primers and probes in units of nanomoles (nM)
- **Salt concentration.** Specifies the concentration of monovalent cations ($[NA^+]$, $[K^+]$ and equivalents) in units of millimoles (mM)

In the *Template panel* the sequences of the chosen primer and the template sequence are shown. The template sequence is as default set to the reverse complement of the primer sequence i.e. as perfectly base-pairing. However, it is possible to edit the template to introduce mismatches which may affect the melting temperature. At each side of the template sequence a text field is shown. Here, the dangling ends of the template sequence can be specified. These may have an important affect on the melting temperature [Bommarito et al., 2000]

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**. The result is shown in figure 18.16:

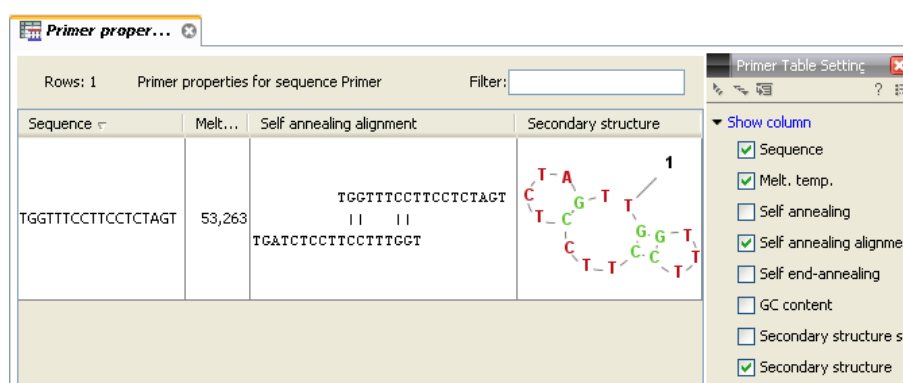

Figure 18.16: Properties of a primer from the Example Data.

In the **Side Panel** you can specify the information to display about the primer. The information parameters of the primer properties table are explained in section 18.5.2.

18.11 Find binding sites and create fragments

In *CLC Main Workbench* you have the possibility of matching known primers against one or more DNA sequences or a list of DNA sequences. This can be applied to test whether a primer used in a previous experiment is applicable to amplify e.g. a homologous region in another species, or to test for potential mispriming. This functionality can also be used to extract the resulting PCR product when two primers are matched. This is particularly useful if your primers have extensions in the 5' end.

To search for primer binding sites:

Toolbox | Primers and Probes (📁) | Find Binding Sites and Create Fragments (🔍)

If a sequence was already selected, this sequence is now listed in the **Selected Elements** window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements.

Click **Next** when all the sequence have been added.

Note! You should not add the primer sequences at this step.

18.11.1 Binding parameters

This opens the dialog displayed in figure 18.17:

At the top, select one or more primers by clicking the browse (📁) button. In *CLC Main Workbench*,

Figure 18.17: Search parameters for finding primer binding sites.

primers are just DNA sequences like any other, but there is a filter on the length of the sequence. Only sequences up to 400 bp can be added.

The **Match criteria** for matching a primer to a sequence are:

- **Exact match.** Choose only to consider exact matches of the primer, i.e. all positions must base pair with the template.
- **Minimum number of base pairs required for a match.** How many nucleotides of the primer that must base pair to the sequence in order to cause priming/mispriming.
- **Number of consecutive base pairs required in 3' end.** How many consecutive 3' end base pairs in the primer that **MUST** be present for priming/mispriming to occur. This option is included since 3' terminal base pairs are known to be essential for priming to occur.

Note that the number of mismatches is reported in the output, so you will be able to filter on this afterwards (see below).

Below the match settings, you can adjust **Concentrations** concerning the reaction mixture. This is used when reporting melting temperatures for the primers.

- **Primer concentration.** Specifies the concentration of primers and probes in units of nanomoles (nM)
- **Salt concentration.** Specifies the concentration of monovalent cations ($[NA^+]$, $[K^+]$ and equivalents) in units of millimoles (mM)

18.11.2 Results - binding sites and fragments

Click **Next** to specify the output options as shown in figure 18.18:

The output options are:

- **Add binding site annotations.** This will add annotations to the input sequences (see details below).

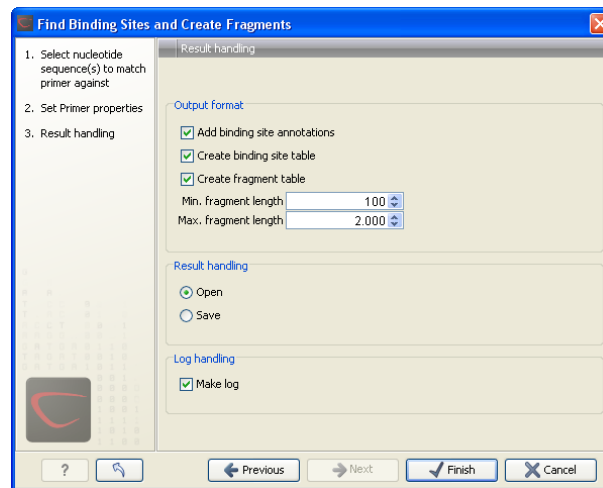

Figure 18.18: Output options include reporting of binding sites and fragments.

- **Create binding site table.** Creates a table of all binding sites. Described in details below.
- **Create fragment table.** Showing a table of all fragments that could result from using the primers. Note that you can set the minimum and maximum sizes of the fragments to be shown. The table is described in detail below.

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

An example of a **binding site annotation** is shown in figure 18.19.

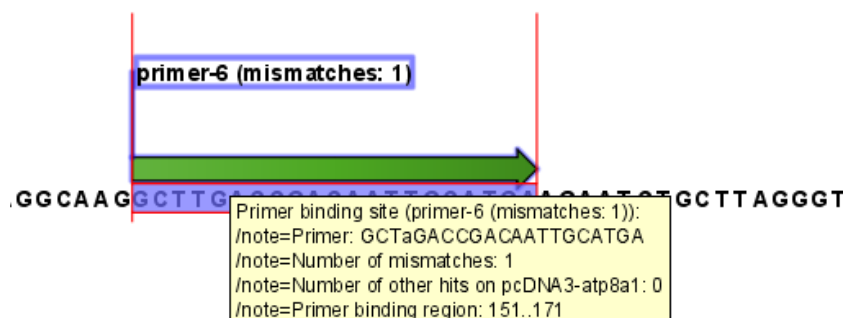

Figure 18.19: Annotation showing a primer match.

The annotation has the following information:

- **Sequence of the primer.** Positions with mismatches will be in lower-case (see the fourth position in figure 18.19 where the primer has an a and the template sequence has a T).
- **Number of mismatches.**
- **Number of other hits on the same sequence.** This number can be useful to check specificity of the primer.
- **Binding region.** This region ends with the 3' exact match and is simply the primer length upstream. This means that if you have 5' extensions to the primer, part of the binding region covers sequence that will actually not be annealed to the primer.

Rows: 8 Binding sites Filter:

Figure 18.20: A table showing all binding sites.

An example of the **primer binding site table** is shown in figure 18.20.

The information here is the same as in the primer annotation and furthermore you can see additional information about melting temperature etc. by selecting the options in the **Side Panel**. See a more detailed description of this information in section 18.5.2. You can use this table to browse the binding sites. If you make a split view of the table and the sequence (see section 3.1.6), you can browse through the binding positions by clicking in the table. This will cause the sequence view to jump to the position of the binding site.

An example of a **fragment table** is shown in figure 18.21.

Rows: 7 Fragments Filter:

Select All
Deselect All

Figure 18.21: A table showing all possible fragments of the specified size.

The table first lists the names of the forward and reverse primers, then the length of the fragment and the region. The last column tells if there are other possible fragments fulfilling the length criteria on this sequence. This information can be used to check for competing products in the PCR. In the **Side Panel** you can show information about melting temperature for the primers as well as the difference between melting temperatures.

You can use this table to browse the fragment regions. If you make a split view of the table and the sequence (see section 3.1.6), you can browse through the fragment regions by clicking in the table. This will cause the sequence view to jump to the start position of the fragment.

There are some additional options in the fragment table. First, you can annotate the fragment on the original sequence. This is done by right-clicking (Ctrl-click on Mac) the fragment and choose **Annotate Fragment** as shown in figure 18.22.

Rows: 7		Fragments		Filter:	
Fwd	Rev	Fragment length	Region	Other f	
primer-3	primer-2	1488	1575..3062		
primer-6	primer-1	751	151..401		
primer-6	primer-5 - HindIII	65	151..1615	Annotate Fragment	
primer-6	primer-5	51	151..1601	Open Fragment	
primer-6- EcoRV	primer-1	269	133..401		
primer-6- EcoRV	primer-5 - HindIII	1483	133..1615		

Figure 18.22: Right-clicking a fragment allows you to annotate the region on the input sequence or open the fragment as a new sequence.

This will put a *PCR fragment* annotations on the input sequence covering the region specified in the table. As you can see from figure 18.22, you can also choose to **Open Fragment**. This will create a new sequence representing the PCR product that would be the result of using these two primers. Note that if you have extensions on the primers, they will be used to construct the new sequence. If you are doing restriction cloning using primers with restriction site extensions, you can use this functionality to retrieve the PCR fragment for us in the cloning editor (see section 21.1).

18.12 Order primers

To facilitate the ordering of primers and probes, *CLC Main Workbench* offers an easy way of displaying, and saving, a textual representation of one or more primers:

select primers in Navigation Area | Toolbox in the Menu Bar | Primers and Probes
 **Order Primers** 

This opens a dialog where you can choose additional primers. Clicking **OK** opens a textual representation of the primers (see figure 18.23). The first line states the number of primers being ordered and after this follows the names and nucleotide sequences of the primers in 5'-3' orientation. From the editor, the primer information can be copied and pasted to web forms or e-mails. The created object can also be saved and exported as a text file.

See figure 18.23

```
Primer order ...  
Number of primers: 4

19.7.3 Sorting reads	394
19.7.4 Read conflicts	394
19.7.5 Output from the contig	394
19.7.6 Extract parts of a contig	395
19.7.7 Variance table	396
19.8 Reassemble contig	398
19.9 Secondary peak calling	398

CLC Main Workbench lets you import, trim and assemble DNA sequence reads from automated sequencing machines. A number of different formats are supported (see section 7.1). This chapter first explains how to trim sequence reads. Next follows a description of how to assemble reads into contigs both with and without a reference sequence. In the final section, the options for viewing and editing contigs are explained.

19.1 Importing and viewing trace data

A number of different binary trace data formats can be imported into the program, including *Standard Chromatogram Format (.SCF)*, *ABI sequencer data files (.ABI and .AB1)*, *PHRED output files (.PHD)* and *PHRAP output files (.ACE)* (see section 7.1).

After import, the sequence reads and their trace data are saved as DNA sequences. This means that all analyzes which apply to DNA sequences can be performed on the sequence reads, including e.g. BLAST and open reading frame prediction.

You can see additional information about the quality of the traces by holding the mouse cursor on the imported sequence. This will display a tooltip as shown in figure 19.1.

Figure 19.1: A tooltip displaying information about the quality of the chromatogram.

The qualities are based on the phred scoring system, with scores below 19 counted as low quality, scores between 20 and 39 counted as medium quality, and those 40 and above counted as high quality.

If the trace file does not contain information about quality, only the sequence length will be shown.

To view the trace data, open the sequence read in a standard sequence view (ACT).

19.1.1 Scaling traces

The traces can be scaled by dragging the trace vertically as shown in figure 19.2. The Workbench automatically adjust the height of the traces to be readable, but if the trace height varies a lot, this manual scaling is very useful.

The height of the area available for showing traces can be adjusted in the **Side Panel** as described in section 19.1.2.

Figure 19.2: Grab the traces to scale.

19.1.2 Trace settings in the Side Panel

In the Nucleotide info preference group the display of trace data can be selected and unselected. When selected, the trace data information is shown as a plot beneath the sequence. The appearance of the plot can be adjusted using the following options (see figure 19.3):

- **Nucleotide trace.** For each of the four nucleotides the trace data can be selected and unselected.

- **Scale traces.** A slider which allows the user to scale the height of the trace area. Scaling the traces individually is described in section 19.1.1.

Figure 19.3: A sequence with trace data. The preferences for viewing the trace are shown in the Side Panel.

19.2 Multiplexing

When you do batch sequencing of different samples, you can use multiplexing techniques to run different samples in the same run. There is often a data analysis challenge to separate the sequencing reads, so that the reads from one sample are mapped together. The *CLC Main Workbench* supports automatic grouping of samples for two multiplexing techniques:

- **By name.** This supports grouping of reads based on their name.
- **By sequence tag.** This supports grouping of reads based on information within the sequence (tagged sequences).

The details of these two functionalities are described below.

19.2.1 Sort sequences by name

With this functionality you will be able to group sequencing reads based on their file name. A typical example would be that you have a list of files named like this:

```
...
A02__Asp_F_016_2007-01-10
A02__Asp_R_016_2007-01-10
A02__Gln_F_016_2007-01-11
A02__Gln_R_016_2007-01-11
A03__Asp_F_031_2007-01-10
```

```
A03__Asp_R_031_2007-01-10
A03__Gln_F_031_2007-01-11
A03__Gln_R_031_2007-01-11
...
```

In this example, the names have five distinct parts (we take the first name as an example):

- **A02** which is the position on the 96-well plate
- **Asp** which is the name of the gene being sequenced
- **F** which describes the orientation of the read (forward/reverse)
- **016** which is an ID identifying the sample
- **2007-01-10** which is the date of the sequencing run

To start mapping these data, you probably want to have them divided into groups instead of having all reads in one folder. If, for example, you wish to map each sample separately, or if you wish to map each gene separately, you cannot simply run the mapping on all the sequences in one step.

That is where **Sort Sequences by Name** comes into play. It will allow you to specify which part of the name should be used to divide the sequences into groups. We will use the example described above to show how it works:

Toolbox | NGS Core Tools (📁) | Multiplexing (📁) | Sort Sequences by Name (🔗)

This opens a dialog where you can add the sequences you wish to sort. You can also add sequence lists or the contents of an entire folder by right-clicking the folder and choose: **Add folder contents**.

When you click **Next**, you will be able to specify the details of how the grouping should be performed. First, you have to choose how each part of the name should be identified. There are three options:

- **Simple**. This will simply use a designated character to split up the name. You can choose a character from the list:
 - Underscore _
 - Dash -
 - Hash (number sign / pound sign) #
 - Pipe |
 - Tilde ~
 - Dot .
- **Positions**. You can define a part of the name by entering the start and end positions, e.g. from character number 6 to 14. For this to work, the names have to be of equal lengths.
- **Java regular expression**. This is an option for advanced users where you can use a special syntax to have total control over the splitting. See more below.

In the example above, it would be sufficient to use a simple split with the underscore `_` character, since this is how the different parts of the name are divided.

When you have chosen a way to divide the name, the parts of the name will be listed in the table at the bottom of the dialog. There is a checkbox next to each part of the name. This checkbox is used to specify which of the name parts should be used for grouping. In the example above, if we want to group the reads according to sample ID and gene name, these two parts should be checked as shown in figure 19.4.

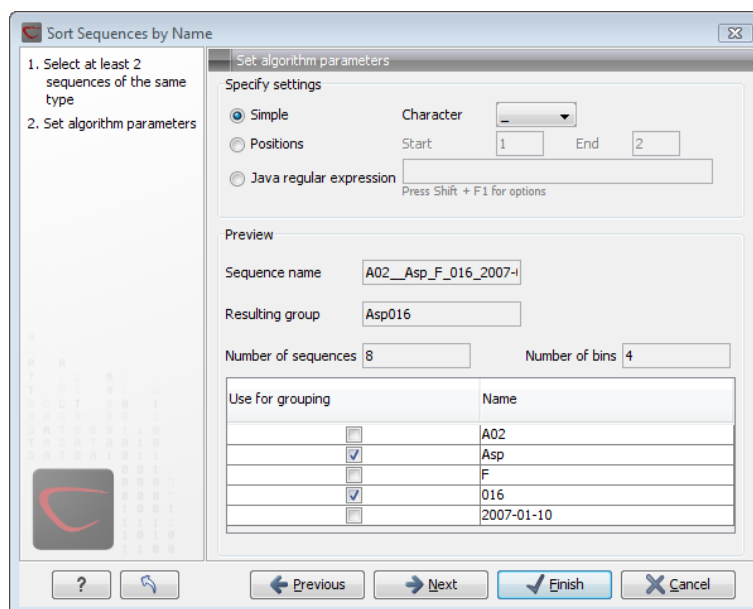

Figure 19.4: Splitting up the name at every underscore (`_`) and using the sample ID and gene name for grouping.

At the middle of the dialog there is a preview panel listing:

- **Sequence name.** This is the name of the first sequence that has been chosen. It is shown here in the dialog in order to give you a sample of what the names in the list look like.
- **Resulting group.** The name of the group that this sequence would belong to if you proceed with the current settings.
- **Number of sequences.** The number of sequences chosen in the first step.
- **Number of groups.** The number of groups that would be produced when you proceed with the current settings.

This preview cannot be changed. It is shown to guide you when finding the appropriate settings.

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**. A new sequence list will be generated for each group. It will be named according to the group, e.g. `Asp016` will be the name of one of the groups in the example shown in figure 19.4.

Advanced splitting using regular expressions

You can see a more detail explanation of the regular expressions syntax in section 15.7.3. In this section you will see a practical example showing how to create a regular expression. Consider a

list of files as shown below:

```

...
adk-29_adk1n-F
adk-29_adk2n-R
adk-3_adk1n-F
adk-3_adk2n-R
adk-66_adk1n-F
adk-66_adk2n-R
atp-29_atpA1n-F
atp-29_atpA2n-R
atp-3_atpA1n-F
atp-3_atpA2n-R
atp-66_atpA1n-F
atp-66_atpA2n-R
...

```

In this example, we wish to group the sequences into three groups based on the number after the "-" and before the "_" (i.e. 29, 3 and 66). The simple splitting as shown in figure 19.4 requires the same character before and after the text used for grouping, and since we now have both a "-" and a "_", we need to use the regular expressions instead (note that dividing by position would not work because we have both single and double digit numbers (3, 29 and 66)).

The regular expression for doing this would be `(.*)-(.*)_(.*)` as shown in figure 19.5. The round brackets `()` denote the part of the name that will be listed in the groups table at the

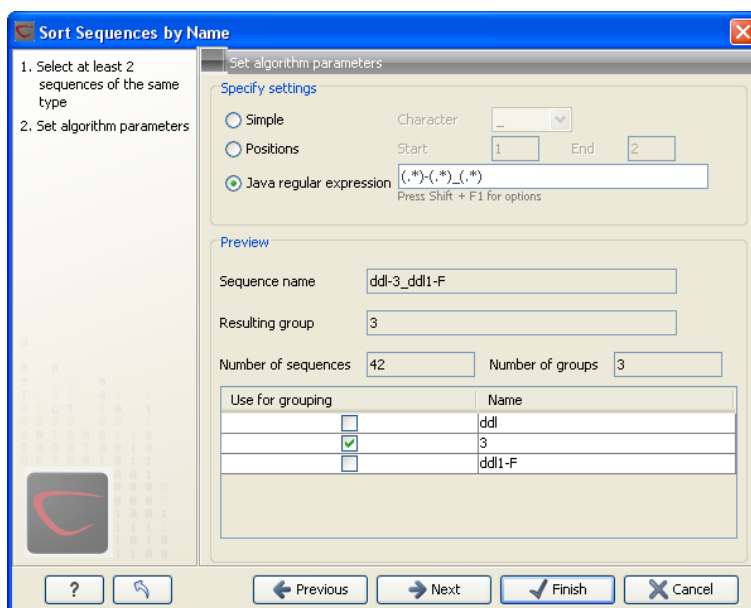

Figure 19.5: Dividing the sequence into three groups based on the number in the middle of the name.

bottom of the dialog. In this example we actually did not need the first and last set of brackets, so the expression could also have been `.*(-.*)_.*` in which case only one group would be listed in the table at the bottom of the dialog.

19.2.2 Process tagged sequences

Multiplexing as described in section 19.2.1 is of course only possible if proper sequence names could be assigned from the sequencing process. With many of the new high-throughput technologies, this is not possible.

However, there is a need for being able to input several different samples to the same sequencing run, so multiplexing is still relevant - it just has to be based on another way of identifying the sequences. A method has been proposed to *tag* the sequences with a unique identifier during the preparation of the sample for sequencing [Meyer et al., 2007].

With this technique, each sequence will have a sample-specific tag - a special sequence of nucleotides before and after the sequence of interest. This principle is shown in figure 19.6 (please refer to [Meyer et al., 2007] for more detailed information).

Figure 19.6: Tagging the target sequence. Figure from [Meyer et al., 2007].

The sample-specific tag - also called the barcode - can then be used to distinguish between the different samples when analyzing the sequence data. This post-processing of the sequencing data has been made easy by the multiplexing functionality of the *CLC Main Workbench* which simply divides the data into separate groups prior to analysis. Note that there is also an example using Illumina data at the end of this section.

The first step is to separate the imported sequence list into sublists based on the barcode of the sequences:

Toolbox | **NGS Core Tools** (📁) | **Multiplexing** (📁) | **Process Tagged Sequences** (🔗)

This opens a dialog where you can add the sequences you wish to sort. You can also add sequence lists.

When you click **Next**, you will be able to specify the details of how the de-multiplexing should be performed. At the bottom of the dialog, there are three buttons which are used to **Add**, **Edit** and **Delete** the elements that describe how the barcode is embedded in the sequences.

First, click **Add** to define the first element. This will bring up the dialog shown in 19.7.

At the top of the dialog, you can choose which kind of element you wish to define:

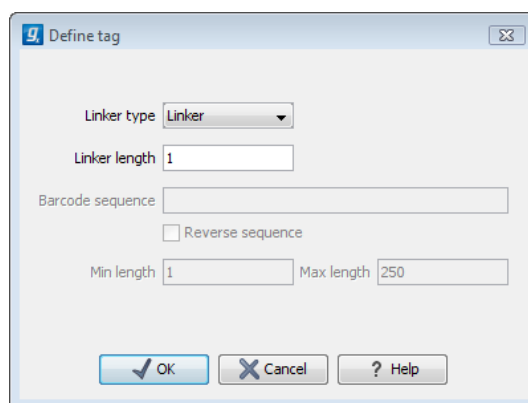

Figure 19.7: Defining an element of the barcode system.

- **Linker.** This is a sequence which should just be ignored - it is neither the barcode nor the sequence of interest. Following the example in figure 19.6, it would be the four nucleotides of the *SrfI* site. For this element, you simply define its length - nothing else.
- **Barcode.** The barcode is the stretch of nucleotides used to group the sequences. For that, you need to define what the valid bases are. This is done when you click **Next**. In this dialog, you simply need to specify the length of the barcode.
- **Sequence.** This element defines the sequence of interest. You can define a length interval for how long you expect this sequence to be. The sequence part is the only part of the read that is retained in the output. Both barcodes and linkers are removed.

The concept when adding elements is that you add e.g. a linker, a barcode and a sequence in the desired sequential order to describe the structure of each sequencing read. You can of course edit and delete elements by selecting them and clicking the buttons below. For the example from figure 19.6, the dialog should include a linker for the *SrfI* site, a barcode, a sequence, a barcode (now reversed) and finally a linker again as shown in figure 19.8.

If you have paired data, the dialog shown in figure 19.8 will be displayed twice - one for each part of the pair.

Clicking **Next** will display a dialog as shown in figure 19.9.

The barcodes can be entered manually by clicking the **Add** (➡) button. You can edit the barcodes and the names by clicking the cells in the table. The name is used for naming the results.

In addition to adding barcodes manually, you can also **Import** (📁) barcode definitions from an Excel or CSV file. The input format consists of two columns: the first contains the barcode sequence, the second contains the name of the barcode. An acceptable csv format file would contain columns of information that looks like:

```
"AAAAAA","Sample1"
"GGGGGG","Sample2"
"CCCCCC","Sample3"
```

The **Preview** column will show a preview of the results by running through the first 10,000 reads.

At the top, you can choose to search on both strands for the barcodes (this is needed for some 454 protocols where the MID is located at either end of the read).

Figure 19.8: Processing the tags as shown in the example of figure 19.6.

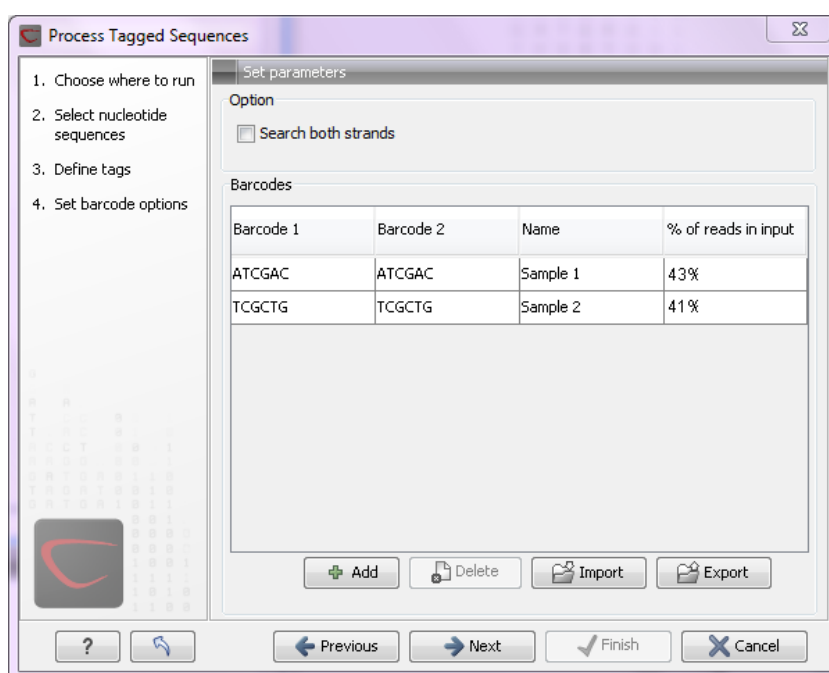

Figure 19.9: Specifying the barcodes as shown in the example of figure 19.6.

Click **Next** to specify the output options. First, you can choose to create a list of the reads that could not be grouped. Second, you can create a summary report showing how many reads were found for each barcode (see figure 19.10).

There is also an option to create subfolders for each sequence list. This can be handy when the results need to be processed in batch mode (see section 9.1).

A new sequence list will be generated for each barcode containing all the sequences where this barcode is identified. Both the linker and barcode sequences are removed from each of

1 Multiplexig summary

1.1 Reads per barcode

Barcode	Number of reads	Percentage of reads
Barcode:GGT	1,745,043	26%
Barcode:CGT	1,305,703	20%
Barcode:AAT	1,850,050	28%
Barcode:CCT	1,251,849	19%
Not grouped	445,560	7%

1.2 Reads per barcode

Figure 19.10: An example of a report showing the number of reads in each group.

the sequences in the list, so that only the target sequence remains. This means that you can continue the analysis by doing trimming or mapping. Note that you have to perform separate mappings for each sequence list.

An example using Illumina barcoded sequences

The data set in this example can be found at the Short Read Archive at NCBI: <http://www.ncbi.nlm.nih.gov/sra/SRX014012>. It can be downloaded directly in fastq format via the URL http://trace.ncbi.nlm.nih.gov/Traces/sra/sra.cgi?cmd=dload&run_list=SRR030730&format=fastq. The file you download can be imported directly into the Workbench.

The barcoding was done using the following tags at the beginning of each read: CCT, AAT, GGT, CGT (see supplementary material of [Cronn et al., 2008] at <http://nar.oxfordjournals.org/cgi/data/gkn502/DC1/1>).

The settings in the dialog should thus be as shown in figure 19.11.

Figure 19.11: Setting the barcode length at three

Click **Next** to specify the bar codes as shown in figure 19.12 (use the **Add** button).

Figure 19.12: A preview of the result

With this data set we got the four groups as expected (shown in figure 19.13). The **Not grouped** list contains 445,560 reads that will have to be discarded since they do not have any of the barcodes.

Figure 19.13: The result is one sequence list per barcode and a list with the remainders

19.3 Trim sequences

CLC Main Workbench offers a number of ways to trim your sequence reads prior to assembly. Trimming can be done either as a separate task before assembling, or it can be performed as an integrated part of the assembly process (see section 19.4).

Trimming as a separate task can be done either manually or automatically.

In both instances, trimming of a sequence does not cause data to be deleted, instead both the manual and automatic trimming will put a "Trim" annotation on the trimmed parts as an indication to the assembly algorithm that this part of the data is to be ignored (see figure 19.14). This means that the effect of different trimming schemes can easily be explored without the loss of data. To remove existing trimming from a sequence, simply remove its trim annotation (see section 11.3.2).

Figure 19.14: Trimming creates annotations on the regions that will be ignored in the assembly process.

Note! If you wish to have the contamination removed completely, you should use the NGS trim tool (see section ??).

19.3.1 Manual trimming

Sequence reads can be trimmed manually while inspecting their trace and quality data. Trimming sequences manually corresponds to adding annotation (see also section 11.3.2) but is special in the sense that trimming can only be applied to the ends of a sequence:

double-click the sequence to trim in the Navigation Area | select the region you want to trim | right-click the selection | Trim sequence left/right to determine the direction of the trimming

This will add a trimming annotation to the end of the sequence in the selected direction. Note

that no sequence is being deleted, in stead the trim annotation signals that the sequence is to be ignored during further analyses).

19.3.2 Automatic trimming

Sequence reads can be trimmed automatically based on a number of different criteria. Automatic trimming is particularly useful in the following situations:

- If you have many sequence reads to be trimmed.
- If you wish to trim vector contamination from sequence reads.
- If you wish to ensure that the trimming is done according to the same criteria for all the sequence reads.

To trim sequences automatically:

select sequence(s) or sequence lists to trim | Toolbox in the Menu Bar | Sequencing Data Analysis (A) | Trim Sequences (T)

This opens a dialog where you can alter your choice of sequences.

When the sequences are selected, click **Next**.

This opens the dialog displayed in figure 19.15.

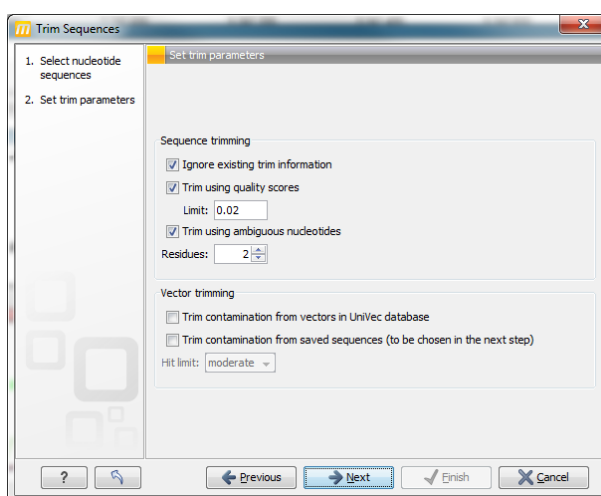

Figure 19.15: Setting parameters for trimming.

The following parameters can be adjusted in the dialog:

- **Ignore existing trim information.** If you have previously trimmed the sequences, you can check this to remove existing trimming annotation prior to analysis.
- **Trim using quality scores.** If the sequence files contain quality scores from a base-caller algorithm this information can be used for trimming sequence ends. The program uses the modified-Mott trimming algorithm for this purpose (Richard Mott, personal communication): Quality scores in the Workbench are on a Phred scale, and formats using other scales will be converted during import. The Phred quality scores (Q), defined as: $Q = -10 \log_{10}(P)$, where

P is the base-calling error probability, can then be used to calculate the error probabilities, which in turn can be used to set the limit for, which bases should be trimmed.

Hence, the first step in the trim process is to convert the quality score (Q) to an error probability: $p_{error} = 10^{-\frac{Q}{10}}$. (This now means that low values are high quality bases.)

Next, for every base a new value is calculated: $Limit - p_{error}$. This value will be negative for low quality bases, where the error probability is high.

For every base, the Workbench calculates the running sum of this value. If the sum drops below zero, it is set to zero. The part of the sequence not trimmed will be the region between the first positive value of the running sum and the highest value of the running sum. Everything before and after this region will be trimmed.

A read will be completely removed if the score never makes it above zero.

At <http://www.clcbio.com/files/usermanuals/trim.zip> you find an example sequence and an Excel sheet showing the calculations done for this particular sequence to illustrate the procedure described above.

- **Trim ambiguous nucleotides.** This option trims the sequence ends based on the presence of ambiguous nucleotides (typically N). Note that the automated sequencer generating the data must be set to output ambiguous nucleotides in order for this option to apply. The algorithm takes as input the *maximal number of ambiguous nucleotides allowed in the sequence after trimming*. If this maximum is set to e.g. 3, the algorithm finds the maximum length region containing 3 or fewer ambiguities and then trims away the ends not included in this region.
- **Trim contamination from vectors in UniVec database.** If selected, the program will match the sequence reads against all vectors in the UniVec database and mark sequence ends with significant matches with a 'Trim' annotation (the database is included when you install the *CLC Main Workbench*). A list of all the vectors in the UniVec database can be found at <http://www.ncbi.nlm.nih.gov/VecScreen/replist.html>.
 - **Hit limit.** Specifies how strictly vector contamination is trimmed. Since vector contamination usually occurs at the beginning or end of a sequence, different criteria are applied for terminal and internal matches. A match is considered terminal if it is located within the first 25 bases at either sequence end. Three match categories are defined according to the expected frequency of an alignment with the same score occurring between random sequences. The *CLC Main Workbench* uses the same settings as VecScreen (<http://www.ncbi.nlm.nih.gov/VecScreen/VecScreen.html>):
 - * **Weak.** Expect 1 random match in 40 queries of length 350 kb
 - Terminal match with Score 16 to 18.
 - Internal match with Score 23 to 24.
 - * **Moderate.** Expect 1 random match in 1,000 queries of length 350 kb
 - Terminal match with Score 19 to 23.
 - Internal match with Score 25 to 29.
 - * **Strong.** Expect 1 random match in 1,000,000 queries of length 350 kb
 - Terminal match with Score ≥ 24 .
 - Internal match with Score ≥ 30 .

Note that selecting e.g. **Weak** will also include matches in the **Moderate** and **Strong** categories.

- **Trim contamination from saved sequences.** This option lets you select your own vector sequences that you know might be the cause of contamination. If you select this option, you will be able to select one or more sequences when you click **Next**.

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**. This will start the trimming process. Views of each trimmed sequence will be shown, and you can inspect the result by looking at the "Trim" annotations (they are colored red as default). Note that the trim annotations are used to signal that this part of the sequence is to be ignored during further analyses, hence the trimmed sequences are not deleted. If there are no trim annotations, the sequence has not been trimmed.

19.4 Assemble sequences

This section describes how to assemble a number of sequence reads into a contig without the use of a reference sequence (a known sequence that can be used for comparison with the other sequences, see section 19.5). To perform the assembly:

select sequences to assemble | Toolbox in the Menu Bar | Sequencing Data Analysis
(AA) | Assemble Sequences (AA)

This opens a dialog where you can alter your choice of sequences which you want to assemble. You can also add sequence lists.

Note! You can assemble a maximum of 2000 sequences at a time.

To assemble more sequences, you need the *CLC Genomics Workbench* (see <http://www.clcbio.com/genomics>).

When the sequences are selected, click **Next**. This will show the dialog in figure 19.16

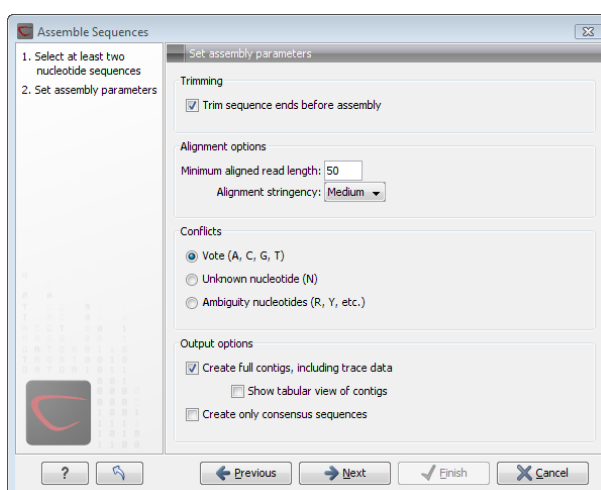

Figure 19.16: Setting assembly parameters.

This dialog gives you the following options for assembling:

- **Trim sequence ends before assembly.** If you have not previously trimmed the sequences,

this can be done by checking this box. If selected, the next step in the dialog will allow you to specify settings for trimming (see section [19.3.2](#)).

- **Minimum aligned read length.** The minimum number of nucleotides in a read which must be successfully aligned to the contig. If this criteria is not met by a read, the read is excluded from the assembly.
- **Alignment stringency.** Specifies the stringency of the scoring function used by the alignment step in the contig assembly algorithm. A higher stringency level will tend to produce contigs with less ambiguities but will also tend to omit more sequencing reads and to generate more and shorter contigs. Three stringency levels can be set:
 - **Low.**
 - **Medium.**
 - **High.**
- **Conflicts.** If there is a conflict, i.e. a position where there is disagreement about the residue (A, C, T or G), you can specify how the contig sequence should reflect the conflict:
 - **Vote (A, C, G, T).** The conflict will be solved by counting instances of each nucleotide and then letting the majority decide the nucleotide in the contig. In case of equality, ACGT are given priority over one another in the stated order.
 - **Unknown nucleotide (N).** The contig will be assigned an 'N' character in all positions with conflicts (conflicts are registered already when two nucleotides differ).
 - **Ambiguity nucleotides (R, Y, etc.).** The contig will display an ambiguity nucleotide reflecting the different nucleotides found in the reads (nucleotide ambiguity is registered already when two nucleotides differ). For an overview of ambiguity codes, see Appendix I.

Note, that conflicts will always be highlighted no matter which of the options you choose. Furthermore, each conflict will be marked as annotation on the contig sequence and will be present if the contig sequence is extracted for further analysis. As a result, the details of any experimental heterogeneity can be maintained and used when the result of single-sequence analyzes is interpreted. Read more about conflicts in section [19.7.4](#).

- **Create full contigs, including trace data.** This will create a contig where all the aligned reads are displayed below the contig sequence. (You can always extract the contig sequence without the reads later on.) For more information on how to use the contigs that are created, see section [19.7](#).
- **Show tabular view of contigs.** A contig can be shown both in a graphical as well as a tabular view. If you select this option, a tabular view of the contig will also be opened (Even if you do not select this option, you can show the tabular view of the contig later on by clicking **Table**  at the bottom of the view.) For more information about the tabular view of contigs, see section [19.7.7](#).
- **Create only consensus sequences.** This will not display a contig but will only output the assembled contig sequences as single nucleotide sequences. If you choose this option it is not possible to validate the assembly process and edit the contig based on the traces.

If you have chosen to "Trim sequences", click **Next** and you will be able to set trim parameters (see section 19.3.2).

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

When the assembly process has ended, a number of views will be shown, each containing a contig of two or more sequences that have been matched. If the number of contigs seem too high or low, try again with another **Alignment stringency** setting. Depending on your choices of output options above, the views will include trace files or only contig sequences. However, the calculation of the contig is carried out the same way, no matter how the contig is displayed.

See section 19.7 on how to use the resulting contigs.

19.5 Assemble to reference sequence

This section describes how to assemble a number of sequence reads into a contig using a reference sequence. A reference sequence can be particularly helpful when the objective is to characterize SNP variation in the data.

To start the assembly:

select sequences to assemble | **Toolbox in the Menu Bar** | **Sequencing Data Analysis**
 | **Assemble Sequences to Reference** 

This opens a dialog where you can alter your choice of sequences that you wish to assemble. You can also add sequence lists.

Note! You can assemble a maximum of 2000 sequences at a time.

To assemble more sequences, you need the *CLC Genomics Workbench* (see <http://www.clcbio.com/genomics>).

When the sequences are selected, click **Next**, and you will see the dialog shown in figure 19.17

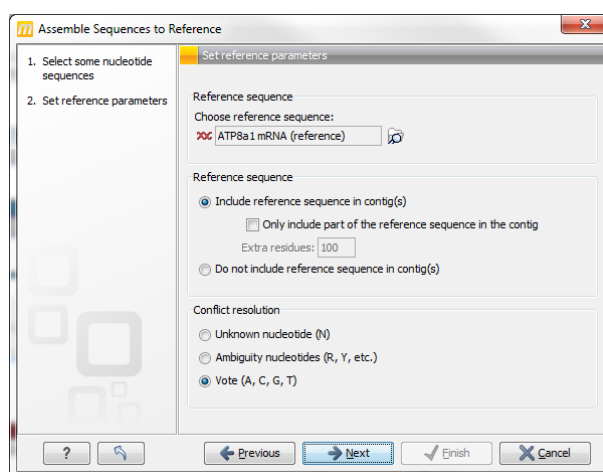

Figure 19.17: Setting assembly parameters when assembling to a reference sequence.

This dialog gives you the following options for assembling:

- **Reference sequence.** Click the **Browse and select element** icon  in order to select a

sequence to use as reference.

- **Include reference sequence in contig(s).** This will display a contig data-object with the reference sequence at the top and the reads aligned below. This option is useful when comparing sequence reads to a closely related reference sequence e.g. when sequencing for SNP characterization.
 - **Only include part of the reference sequence in the contig.** If the aligned sequence reads only cover a small part of the reference sequence, it may not be desirable to include the whole reference sequence in the contig data-object. When selected, this option lets you specify how many residues from the reference sequence that should be kept on each side of the region spanned by sequencing reads by entering the number in the **Extra residues** field.
- **Do not include reference sequence in contig(s).** This will produce a contig data-object without the reference sequence. The contig is created in the same way as when you make an ordinary assembly (see section 19.4), but the reference sequence is omitted in the resulting contig. In the assembly process the reference sequence is only used as a scaffold for alignment. This option is useful when performing assembly with a reference sequence that is not closely related to the sequencing reads.
 - **Conflicts resolved with.** If there is a conflict, i.e. a position where there is disagreement about the residue (A, C, T or G), you can specify how the contig sequence should reflect this conflict:
 - * **Unknown nucleotide (N).** The contig will be assigned an 'N' character in all positions with conflicts (conflicts are registered already when two nucleotides differ).
 - * **Ambiguity nucleotides (R, Y, etc.).** The contig will display an ambiguity nucleotide reflecting the different nucleotides found in the reads (nucleotide ambiguity is registered already when two nucleotides differ). For an overview of ambiguity codes, see Appendix I.
 - * **Vote (A, C, G, T).** The conflict will be solved by counting instances of each nucleotide and then letting the majority decide the nucleotide in the contig. In case of equality, ACGT are given priority over one another in the stated order.

Note, that conflicts will always be highlighted no matter which of the options you choose. Furthermore, each conflict will be marked as annotation on the contig sequence and will be present if the contig sequence is extracted for further analysis. As a result, the details of any experimental heterogeneity can be maintained and used when the result of single-sequence analyzes is interpreted.

When the parameters have been adjusted, click **Next**, to see the dialog shown in figure 19.18

In this dialog, you can specify more options:

- **Minimum aligned read length.** The minimum number of nucleotides in a read which must be successfully aligned to the contig. If this criteria is not met by a read, this is excluded from the assembly.
- **Alignment stringency.** Specifies the stringency of the scoring function used by the alignment step in the contig assembly algorithm. A higher stringency level will tend to produce contigs

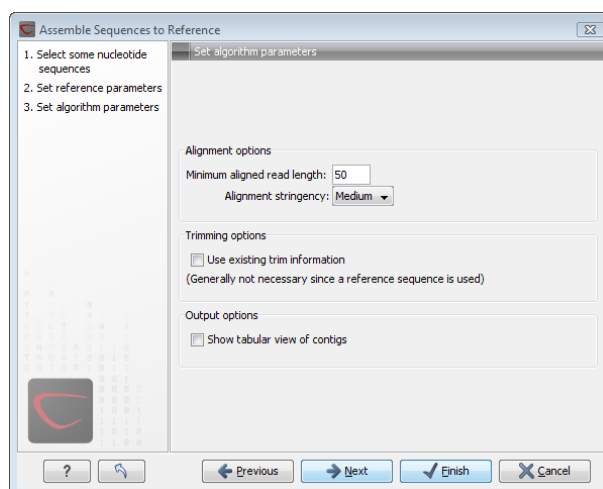

Figure 19.18: Different options for the output of the assembly.

with less ambiguities but will also tend to omit more sequencing reads and to generate more and shorter contigs. Three stringency levels can be set:

- **Low.**
- **Medium.**
- **High.**

The stringency settings Low, Medium and High are based on the following score values (mt=match, ti=transition, tv=transversion, un=unknown):

Score values			
	Low	Medium	High
Match (mt)	2	2	2
Transversion (tv)	-6	-10	-20
Transition (ti)	-2	-6	-16
Unknown (un)	-2	-6	-16
Gap	-8	-16	-36

Score Matrix					
	A	C	G	T	N
A	mt	tv	ti	tv	un
C	tv	mt	tv	ti	un
G	ti	tv	mt	tv	un
T	tv	ti	tv	mt	un
N	un	un	un	un	un

- **Use existing trim information.** When using a reference sequence, trimming is generally not necessary, but if you wish to use trimming you can check this box. It requires that the sequence reads have been trimmed beforehand (see section 19.3 for more information about trimming).
- **Show tabular view of contigs.** A contig can be shown both in a graphical as well as a tabular view. If you select this option, a tabular view of the contig will also be opened (Even

if you do not select this option, you can show the tabular view of the contig later on by clicking **Show** (📄) and selecting **Table** (📊). For more information about the tabular view of contigs, see section 19.7.7.

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**. This will start the assembly process. See section 19.7 on how to use the resulting contigs.

19.6 Add sequences to an existing contig

This section describes how to assemble sequences to an existing contig. This feature can be used for example to provide a steady work-flow when a number of exons from the same gene are sequenced one at a time and assembled to a reference sequence.

Note that the new sequences will be added to the existing contig which will not be extended. If the new sequences extend beyond the existing contig, they will be cut off.

To start the assembly:

select one contig and a number of sequences | Toolbox in the Menu Bar | Sequencing Data Analysis (🔍) | Add Sequences to Contig (📄)

or **right-click in the empty white area of the contig | Add Sequences to Contig (📄)**

This opens a dialog where you can alter your choice of sequences which you want to assemble. You can also add sequence lists.

When the elements are selected, click **Next**, and you will see the dialog shown in figure 19.19

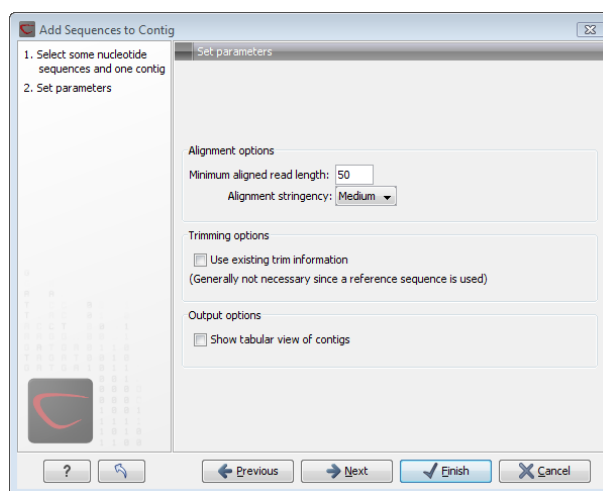

Figure 19.19: Setting assembly parameters when assembling to an existing contig.

The options in this dialog are similar to the options that are available when assembling to a reference sequence (see section 19.5).

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**. This will start the assembly process. See section 19.7 on how to use the resulting contig.

Note that the new sequences will be added to the existing contig which will not be extended. If the new sequences extend beyond the existing contig, they will be cut off.

19.7 View and edit contigs

The result of the assembly process is one or more contigs where the sequence reads have been aligned (see figure 19.20).

Figure 19.20: The view of a contig. Notice that you can zoom to a very detailed level in contigs.

You can see that color of the residues and trace at the end of one of the reads has been faded. This indicates, that this region has not contributed to the contig. This may be due to trimming before or during the assembly or due to misalignment to the other reads.

You can easily adjust the trimmed area to include more of the read in the contig: simply drag the edge of the faded area as shown in figure 19.21.

Figure 19.21: Dragging the edge of the faded area.

Note! This is only possible when you can see the residues on the reads. This means that you need to have zoomed in to 100% or more and chosen **Compactness** levels "Not compact", "Low" or "Packed". Otherwise the handles for dragging are not available (this is done in order to make the visual overview more simple).

If reads have been reversed, this is indicated by red. Otherwise, the residues are colored green. The colors can be changed in the **Side Panel** as described in section 19.7.1

If you find out that the reversed reads should have been the forward reads and vice versa, you can reverse complement the whole contig (imagine flipping the whole contig):

right-click in the empty white area of the contig | Reverse Complement

19.7.1 View settings in the Side Panel

Apart from this the view resembles that of alignments (see section 22.2) but has some extra preferences in the **Side Panel**:

- **Read layout.** A new preference group located at the top of the **Side Panel**:
 - **Compactness** The compactness is an overall setting that lets you control the level of detail to be displayed on the sequencing reads. Please note that this setting affects many of the other settings in the **Side Panel** and the general behavior of the view as well. For example: if the compactness is set to **Compact**, you will not be able to see quality scores or annotations on the reads, no matter how this is specified in the respective settings. And when the compactness is **Packed**, it is not possible to edit the bases of any of the reads. There is a shortcut way of changing the compactness: Press and hold the Alt key while you scroll using your mouse wheel or touchpad.
 - * **Not compact.** The normal setting with full detail. If you wish to view trace data within the mapping, this option should be chosen. See also section 19.1.2
 - * **Low.** Hides trace data, quality scores and puts the reads' annotations on the sequence.
 - * **Medium.** The labels of the reads and their annotations are hidden, and the residues of the reads cannot be seen.
 - * **Compact.** Even less space between the reads.
 - * **Packed.** All the other compactness settings will stack the reads on top of each other, but the packed setting will use all space available for displaying the reads. When zoomed in to 100%, you can see the residues but when zoomed out the reads will be represented as lines just as with the Compact setting. Please note that the packed mode is special because it does not allow any editing of the read sequences and selections, and furthermore the color coding that can be specified elsewhere in the Side Panel does not take effect. An example of the packed compactness setting is shown in figure 19.22.
 - **Gather sequences at top.** Enabling this option affects the view that is shown when scrolling horizontally. If selected, the sequence reads which did not contribute to the visible part of the mapping will be omitted whereas the contributing sequence reads will automatically be placed right below the reference. This setting is not relevant when the compactness is packed.
 - **Show sequence ends.** Regions that have been trimmed are shown with faded traces and residues. This illustrates that these regions have been ignored during the assembly.
 - **Show mismatches.** When the compactness is packed, you can highlight mismatches which will get a color according to the Rasmol color scheme. A mismatch is whenever the base is different from the reference sequence at this position. This setting also causes the reads that have mismatches to be floated at the top of the view.
 - **Disconnect pairs.** This option will break up the paired reads in the display (they are still marked as pairs - this is just affects the visualization). The reads are marked with colors for the direction (default red and green) instead of the color for pairs (default blue). This is particularly useful when investigating overlapping pairs in packed view and when the strand / read orientation is important.

- **Packed read height.** When the compactness is packed, you can choose the height of the visible reads. When there are more reads than the height specified, an overflow graph will be displayed below the reads.
- **Find Conflict.** Clicking this button selects the next position where there is a conflict between the sequence reads. Residues that are different from the reference are colored (as default), providing an overview of the conflicts. Since the next conflict is automatically selected it is easy to make changes. You can also use the Space key to find the next conflict.
- **Alignment info.** There is one additional parameter:
 - **Coverage:** Shows how many sequence reads that are contributing information to a given position in the contig. The level of coverage is relative to the overall number of sequence reads.
 - * **Foreground color.** Colors the letters using a gradient, where the left side color is used for low coverage and the right side is used for maximum coverage.
 - * **Background color.** Colors the background of the letters using a gradient, where the left side color is used for low coverage and the right side is used for maximum coverage
 - * **Graph.** The coverage is displayed as a graph (Learn how to export the data behind the graph in section 7.4).
 - **Height.** Specifies the height of the graph.
 - **Type.** The graph can be displayed as Line plot, Bar plot or as a Color bar.
 - **Color box.** For Line and Bar plots, the color of the plot can be set by clicking the color box. If a Color bar is chosen, the color box is replaced by a gradient color box as described under Foreground color.
- **Residue coloring.** There is one additional parameter:
 - **Sequence colors.** This option lets you use different colors for the reads.
 - * **Main.** The color of the consensus and reference sequence. Black per default.
 - * **Forward.** The color of forward reads (single reads). Green per default.
 - * **Reverse.** The color of reverse reads (single reads). Red per default.
 - * **Paired.** The color of paired reads. Blue per default. Note that reads from **broken pairs** are colored according to their Forward/Reverse orientation or as a Non-specific match, but with a darker nuance than ordinary single reads.
 - * **Non-specific matches.** When a read would have matched equally well another place in the mapping, it is considered a non-specific match. This color will "override" the other colors. Note that if you are mapping with several reference sequences, a read is considered a double match when it matches more than once *across all the contigs/references*. A non-specific match is yellow per default.

Beside from these preferences, all the functionalities of the alignment view are available. This means that you can e.g. add annotations (such as SNP annotations) to regions of interest.

However, some of the parameters from alignment views are set at a different default value in the view of contigs. Trace data of the sequencing reads are shown if present (can be enabled and disabled under the Nucleotide info preference group), and the **Color different residues** option is also enabled in order to provide a better overview of conflicts (can be changed in the Alignment info preference group).

Figure 19.22: An example of the packed compactness setting.

19.7.2 Editing the contig

When editing contigs, you are typically interested in confirming or changing single bases, and this can be done simply by:

selecting the base | typing the right base

Some users prefer to use lower-case letters in order to be able to see which bases were altered when they use the results later on. In *CLC Main Workbench* all changes are recorded in the history log (see section 8) allowing the user to quickly reconstruct the actions performed in the editing session.

There are three shortcut keys for easily finding the positions where there are conflicts:

- Space bar: Finds the *next* conflict.
- "." (punctuation mark key): Finds the *next* conflict.
- "," (comma key): Finds the *previous* conflict.

In the contig view, you can use **Zoom in** (🔍) to zoom to a greater level of detail than in other views (see figure 19.20). This is useful for discerning the trace curves.

If you want to replace a residue with a gap, use the **Delete** key.

If you wish to edit a selection of more than one residue:

right-click the selection | Edit Selection (✎)

This will show a warning dialog, but you can choose never to see this dialog again by clicking the checkbox at the bottom of the dialog.

Note that for contigs with more than 1000 reads, you can only do single-residue replacements (you can't delete or edit a selection). When the compactness is **Packed**, you cannot edit any of the reads.

19.7.3 Sorting reads

If you wish to change the order of the sequence reads, simply drag the label of the sequence up and down. Note that this is not possible if you have chosen **Gather sequences at top** or set the compactness to **Packed** in the **Side Panel**.

You can also sort the reads by right-clicking a sequence label and choose from the following options:

- **Sort Reads by Alignment Start Position.** This will list the first read in the alignment at the top etc.
- **Sort Reads by Name.** Sort the reads alphabetically.
- **Sort Reads by Length.** The shortest reads will be listed at the top.

19.7.4 Read conflicts

When the contig is created, conflicts between the reads are annotated on the consensus sequence. The definition of a conflict is *a position where at least one of the reads have a different residue*.

A conflict can be in two states:

- **Conflict.** Both the annotation and the corresponding row in the Table  are colored **red**.
- **Resolved.** Both the annotation and the corresponding row in the Table  are colored **green**.

The conflict can be resolved by correcting the deviating residues in the reads as described above.

A fast way of making all the reads reflect the consensus sequence is to select the position in the consensus, right-click the selection, and choose **Transfer Selection to All Reads**.

The opposite is also possible: make a selection on one of the reads, right click, and **Transfer Selection to Contig Sequence**.

19.7.5 Output from the contig

Due to the integrated nature of *CLC Main Workbench* it is easy to use the consensus sequences as input for additional analyses. If you wish to extract the consensus sequence for further use, use the **Extract Consensus Sequence** tool (see section ??).

You can also right-click the consensus sequence and select **Open Sequence**. This will not create a new sequence but simply let you see the sequence in a sequence view. This means that the sequence still "belong" to the contig and will be saved together with the contig. It also means that if you add annotations to the sequence, they will be shown in the contig view as well. This can be very convenient e.g. for Primer design .

If you wish to BLAST the consensus sequence, simply select the whole contig for your BLAST search. It will automatically extract the consensus sequence and perform the BLAST search.

In order to preserve the history of the changes you have made to the contig, the contig itself should be saved from the contig view, using either the save button (📁) or by dragging it to the **Navigation Area**.

19.7.6 Extract parts of a contig

Sometimes it is useful to extract part of a contig for in-depth analysis. This could be the case if you have performed an assembly of several genes and you want to look at a particular gene or region in isolation.

This is possible through the right-click menu of the reference or consensus sequence:

**Select on the reference or consensus sequence the part of the contig to extract |
Right-click | Extract from Selection**

This will present the dialog shown in figure 19.23.

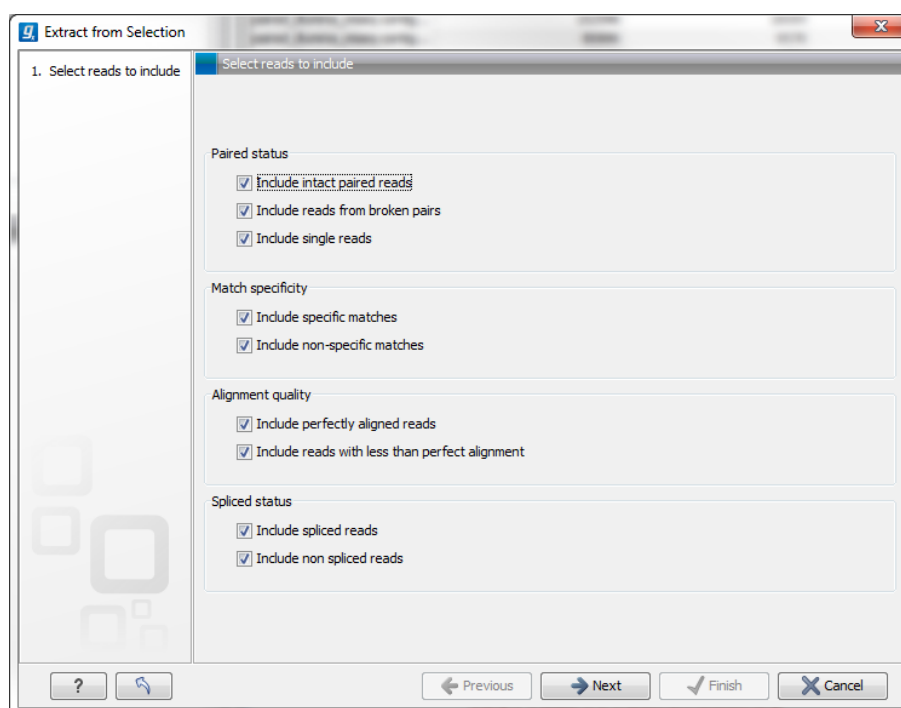

Figure 19.23: *Selecting the reads to include.*

The purpose of this dialog is to let you specify what kind of reads you want to include. Per default all reads are included. The options are:

Paired status Include intact paired reads When paired reads are placed within the paired distance specified, they will fall into this category. Per default, these reads are colored in blue.

Include paired reads from broken pairs When a pair is broken, either because only one read in the pair matches, or because the distance or relative orientation is wrong, the reads are placed and colored as single reads, but you can still extract them by checking this box.

Include single reads This will include reads that are marked as single reads (as opposed to paired reads). Note that paired reads that have been broken during assembly are

not included in this category. Single reads that come from trimming paired sequence lists are included in this category.

Match specificity **Include specific matches** Reads that only are mapped to one position.

Include non-specific matches Reads that have multiple equally good alignments to the reference. These reads are colored yellow per default.

Alignment quality **Include perfectly aligned reads** Reads where *the full read* is perfectly aligned to the reference sequence (or consensus sequence for de novo assemblies). Note that at the end of the contig, reads may extend beyond the contig (this is not visible unless you make a selection on the read and observe the position numbering in the status bar). Such reads are not considered perfectly aligned reads because they don't align in their entire length.

Include reads with less than perfect alignment Reads with mismatches, insertions or deletions, or with unaligned nucleotides at the ends (the faded part of a read).

Spliced status **Include spliced reads** Reads that are across an intron.

Include non spliced reads Reads that are not across an intron.

Note that only reads that are completely covered by the selection will be part of the new contig.

One of the benefits of this is that you can actually use this tool to extract subset of reads from a contig. An example work flow could look like this:

1. Select the whole reference sequence
2. Right-click and **Extract from Selection**
3. Choose to include only paired matches
4. Extract the reads from the new file (see section [11.7.3](#))

You will now have all paired reads from the original mapping in a list.

19.7.7 Variance table

In addition to the standard graphical display of a contig as described above, you can also see a tabular overview of the conflicts between the reads by clicking the **Table**  icon at the bottom of the view.

This will display a new view of the conflicts as shown in figure [19.24](#).

The table has the following columns:

- **Reference position.** The position of the conflict measured from the starting point of the reference sequence.
- **Consensus position.** The position of the conflict measured from the starting point of the consensus sequence.
- **Consensus residue.** The consensus's residue at this position. The residue can be edited in the graphical view, as described above.

Figure 19.24: The graphical view is displayed at the top. At the bottom the conflicts are shown in a table. At the conflict at position 637, the user has entered a comment in the table. This comment is now also reflected on the tooltip of the conflict annotation in the graphical view above.

- Other residues.** Lists the residues of the reads. Inside the brackets, you can see the number of reads having this residue at this position. In the example in figure 19.24, you can see that at position 637 there is a 'C' in the top read in the graphical view. The other two reads have a 'T'. Therefore, the table displays the following text: 'C (1), T (2)'.
- IUPAC.** The ambiguity code for this position. The ambiguity code reflects the residues in the reads - not in the consensus sequence. (The IUPAC codes can be found in section I.)
- Status.** The status can either be conflict or resolved:
 - **Conflict.** Initially, all the rows in the table have this status. This means that there is one or more differences between the sequences at this position.
 - **Resolved.** If you edit the sequences, e.g. if there was an error in one of the sequences, and they now all have the same residue at this position, the status is set to *Resolved*.
- Note.** Can be used for your own comments on this conflict. Right-click in this cell of the table to add or edit the comments. The comments in the table are associated with the conflict annotation in the graphical view. Therefore, the comments you enter in the table will also be attached to the annotation on the consensus sequence (the comments can be

displayed by placing the mouse cursor on the annotation for one second - see figure 19.24). The comments are saved when you **Save** (📁).

By clicking a row in the table, the corresponding position is highlighted in the graphical view. Clicking the rows of the table is another way of navigating the contig, apart from using the **Find Conflict** button or using the **Space bar**. You can use the up and down arrow keys to navigate the rows of the table.

19.8 Reassemble contig

If you have edited a contig, changed trimmed regions, or added or removed reads, you may wish to reassemble the contig. This can be done in two ways:

Toolbox in the Menu Bar | Sequencing Data Analysis (🔧) | Reassemble Contig (🔄) | select the contig and click Next

or **right-click in the empty white area of the contig | Reassemble contig (🔄)**

This opens a dialog as shown in figure 19.25

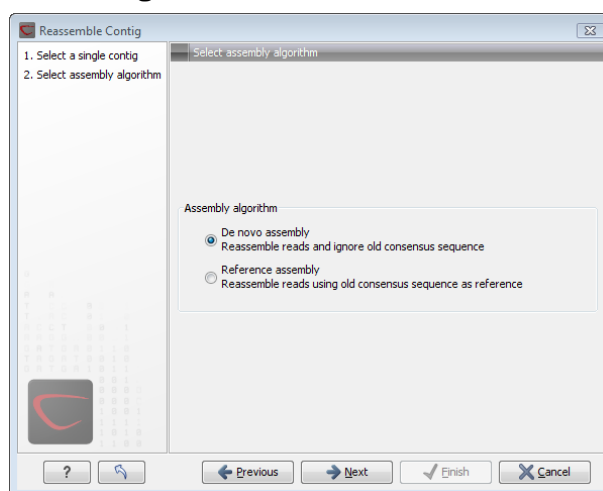

Figure 19.25: Re-assembling a contig.

In this dialog, you can choose:

- **De novo assembly.** This will perform a normal assembly in the same way as if you had selected the reads as individual sequences. When you click **Next**, you will follow the same steps as described in section 19.4. The consensus sequence of the contig will be ignored.
- **Reference assembly.** This will use the consensus sequence of the contig as reference. When you click **Next**, you will follow the same steps as described in section 19.5.

When you click **Finish**, a new contig is created, so you do not lose the information in the old contig.

19.9 Secondary peak calling

CLC Main Workbench is able to detect secondary peaks - a peak within a peak - to help discover

heterozygous mutations. Looking at the height of the peak below the top peak, the *CLC Main Workbench* considers all positions in a sequence, and if a peak is higher than the threshold set by the user, it will be "called".

The peak is called by changing the residue to an ambiguity character and by adding an annotation at this position.

To call secondary peaks:

**select sequence(s) | Toolbox in the Menu Bar | Sequencing Data Analysis (A)|
Call Secondary Peaks (A)**

This opens a dialog where you can alter your choice of sequences.

When the sequences are selected, click **Next**.

This opens the dialog displayed in figure 19.26.

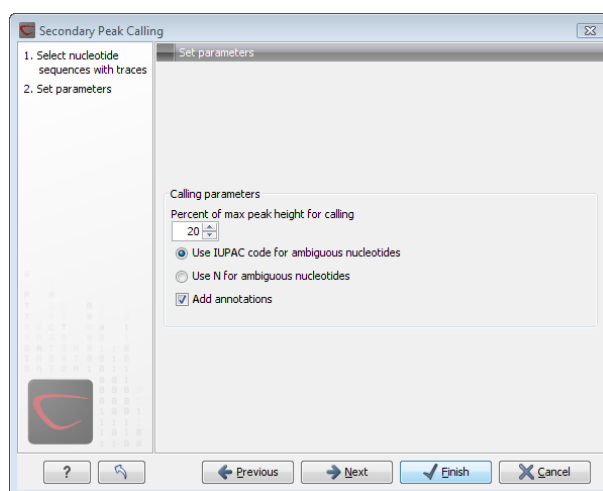

Figure 19.26: Setting parameters secondary peak calling.

The following parameters can be adjusted in the dialog:

- **Percent of max peak height for calling.** Adjust this value to specify how high the secondary peak must be to be called.
- **Use IUPAC code / N for ambiguous nucleotides.** When a secondary peak is called, the residue at this position can either be replaced by an N or by a ambiguity character based on the IUPAC codes (see section I).
- **Add annotations.** In addition to changing the actual sequence, annotations can be added for each base which has been called.

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**. This will start the secondary peak calling. A detailed history entry will be added to the history specifying all the changes made to the sequence.

20.7.3 Scatter plot	456

The *CLC Main Workbench* is able to analyze expression data produced on microarray platforms and high-throughput sequencing platforms (also known as Next-Generation Sequencing platforms).

Note that the *CLC Main Workbench* is not able to calculate expression levels based on the raw sequence data. This analysis has to be performed with the *CLC Genomics Workbench*. The result of this analysis can be imported and further analyzed in the *CLC Main Workbench*.

The *CLC Main Workbench* provides tools for performing quality control of the data, transformation and normalization, statistical analysis to measure differential expression and annotation-based tests. A number of visualization tools such as volcano plots, MA plots, scatter plots, box plots and heat maps are used to aid the interpretation of the results.

20.1 Experimental design

In order to make full use of the various tools for interpreting expression data, you need to know the central concepts behind the way the data is organized in the *CLC Main Workbench*.

The first piece of data you are faced with is the **sample**. In the Workbench, a sample contains the expression values from either one array or from sequencing data of one sample. Note that the *CLC Main Workbench* is not able to calculate expression levels based on the raw sequence data. This analysis has to be performed with the *CLC Genomics Workbench*. The result of this analysis can be imported and further analyzed in the *CLC Main Workbench*.

See more below on how to get your expression data into the Workbench as samples (under Supported array platforms).

In a sample, there is a number of **features**, usually genes, and their associated expression levels.

To analyze differential expression, you need to tell the workbench how the samples are related. This is done by setting up an **experiment**. An experiment is essentially a set of samples which are grouped. By creating an experiment defining the relationship between the samples, it becomes possible to do statistical analysis to investigate differential expression between the groups. The **Experiment** is also used to accumulate calculations like t-tests and clustering because this information is closely related to the grouping of the samples.

20.1.1 Supported array platforms

The workbench supports analysis of one-color expression arrays. These may be imported from GEO soft sample- or series- file formats, or for Affymetrix arrays, tab-delimited pivot or metrics files, or from Illumina expression files. Expression array data from other platforms may be imported from tab, semi-colon or comma separated files containing the expression feature IDs and levels in a tabular format (see see section [K.5](#)).

The workbench assumes that expression values are given at the gene level, thus probe-level analysis of e.g. Affymetrix GeneChips and import of Affymetrix CEL and CDF files is currently not supported. However, the workbench allows import of txt files exported from R containing processed Affymetrix CEL-file data (see see section [K.2](#)).

Affymetrix NetAffx annotation files for expression GeneChips in csv format and Illumina annotation

files can also be imported. Also, you may import your own annotation data in tabular format see section K.5).

See section K in the Appendix for detailed information about supported file formats.

20.1.2 Setting up an experiment

To set up an experiment:

Toolbox | Transcriptomics Analysis (📁) | Set Up Experiment (🛠️)

Select the samples that you wish to use by double-clicking or selecting and pressing the **Add** (➡️) button (see figure 20.1).

Figure 20.1: Select the samples to use for setting up the experiment.

Note that we use "samples" as the general term for both microarray-based sets of expression values and sequencing-based sets of expression values.

Clicking **Next** shows the dialog in figure 20.2.

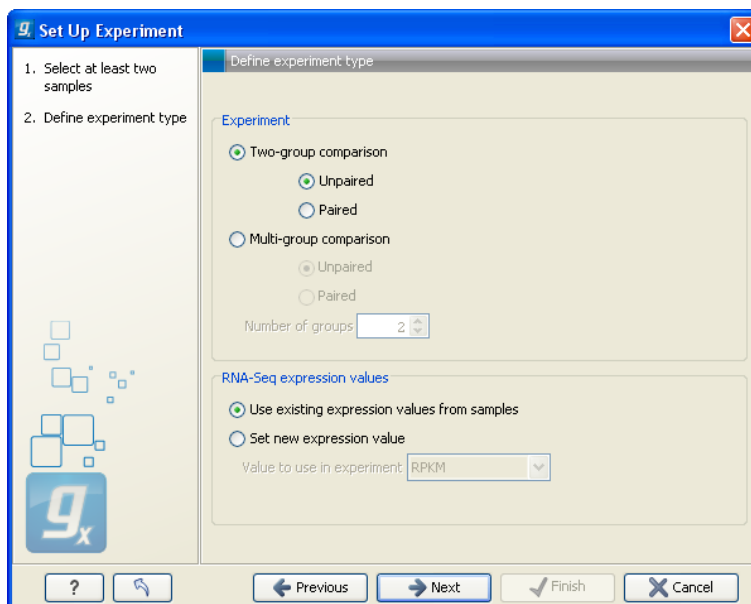

Figure 20.2: Defining the number of groups.

Here you define the number of groups in the experiment. At the top you can select a two-group

experiment, and below you can select a multi-group experiment and define the number of groups.

Note that you can also specify if the samples are paired. Pairing is relevant if you have samples from the same individual under different conditions, e.g. before and after treatment, or at times 0, 2 and 4 hours after treatment. In this case statistical analysis becomes more efficient if effects of the individuals are taken into account, and comparisons are carried out not simply by considering *raw* group means but by considering these *corrected* for effects of the individual. If the **Paired** is selected, a paired rather than a standard t-test will be carried out for two group comparisons. For multiple group comparisons a repeated measures rather than a standard ANOVA will be used.

For RNA-Seq experiments, you can also choose which expression value to be used when setting up the experiment. This value will then be used for all subsequence analyses.

Clicking **Next** shows the dialog in figure 20.3.

Figure 20.3: Naming the groups.

Depending on the number of groups selected in figure 20.2, you will see a list of groups with text fields where you can enter an appropriate name for that group.

For multi-group experiments, if you find out that you have too many groups, click the **Delete** (X) button. If you need more groups, simply click **Add New Group**.

Click **Next** when you have named the groups, and you will see figure 20.4.

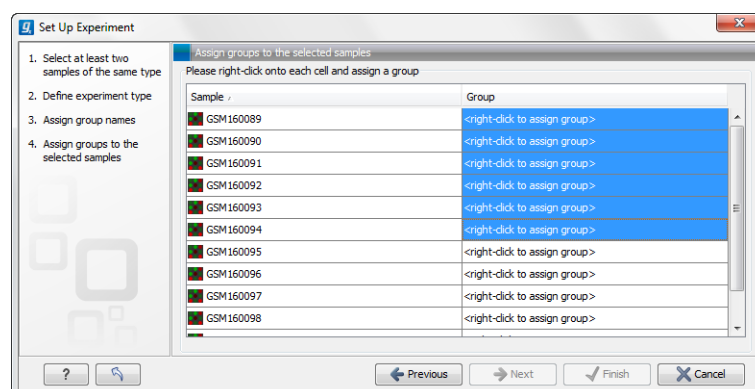

Figure 20.4: Putting the samples into groups.

This is where you define which group the individual sample belongs to. Simply select one or

more samples (by clicking and dragging the mouse), right-click (Ctrl-click on Mac) and select the appropriate group.

Note that the samples are sorted alphabetically based on their names.

If you have chosen **Paired** in figure 20.2, there will be an extra column where you define which samples belong together. Just as when defining the group membership, you select one or more samples, right-click in the pairing column and select a pair.

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

20.1.3 Organization of the experiment table

The resulting experiment includes all the expression values and other information from the samples (the values are copied - the original samples are not affected and can thus be deleted with no effect on the experiment). In addition it includes a number of summaries of the values across all, or a subset of, the samples for each feature. Which values are included is described in the sections below.

When you open it, it is shown in the experiment table (see figure 20.5).

Feature ID	Experiment				Express
	Range (orig...)	IQR (origin...)	Difference (...)	Fold Chang...	
0610006I08...	19,92	16,78	-17,68	-1,61	
0610006L0...	0,00	0,00	0,00	1,00	
0610007C2...	26,01	25,89	25,34	1,50	
0610007L0...	6,41	5,74	5,92	1,41	
0610007N1...	1,18	0,97	-1,04	-3,09	
0610007P0...	-∞	0,28	0,44	1,54	
0610007P1...	2,87	1,97	-2,34	-1,08	
0610007P2...	10,52	6,76	-7,33	-1,67	
0610008C0...	2,41	2,41	1,71	1,27	
0610009B2...	-∞	6,39	4,47	1,33	
0610009D0...	0,70	0,29	0,48	1,03	
0610009K1...	13,42	12,57	-12,51	-2,20	
0610009O0...	6,08	5,76	-5,60	-5,03	
0610009O2...	9,88	7,61	-8,06	-1,69	

Figure 20.5: Opening the experiment.

For a general introduction to table features like sorting and filtering, see section C.

Unlike other tables in *CLC Main Workbench*, the experiment table has a hierarchical grouping of the columns. This is done to reflect the structure of the data in the experiment. The **Side Panel** is divided into a number of groups corresponding to the structure of the table. These are described

below. Note that you can customize and save the settings of the **Side Panel** (see section 5.6).

Whenever you perform analyses like normalization, transformation, statistical analysis etc, new columns will be added to the experiment. You can at any time **Export** (📄) all the data in the experiment in csv or Excel format or **Copy** (📄) the full table or parts of it.

Column width

There are two options to specify the width of the columns and also the entire table:

- **Automatic.** This will fit the entire table into the width of the view. This is useful if you only have a few columns.
- **Manual.** This will adjust the width of all columns evenly, and it will make the table as wide as it needs to be to display all the columns. This is useful if you have many columns. In this case there will be a scroll bar at the bottom, and you can manually adjust the width by dragging the column separators.

Experiment level

The rest of the **Side Panel** is devoted to different levels of information on the values in the experiment. The experiment part contains a number of columns that, for each feature ID, provide summaries of the values across all the samples in the experiment (see figure 20.6).

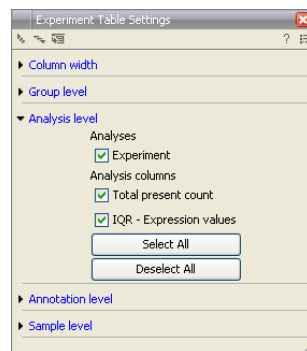

Figure 20.6: The initial view of the experiment level for a two-group experiment.

Initially, it has one header for the whole **Experiment**:

- **Range (original values).** The 'Range' column contains the difference between the highest and the lowest expression value for the feature over all the samples. If a feature has the value NaN in one or more of the samples the range value is NaN.
- **IQR (original values).** The 'IQR' column contains the inter-quantile range of the values for a feature across the samples, that is, the difference between the 75 %-ile value and the 25 %-ile value. For the IQR values, only the numeric values are considered when percentiles are calculated (that is, NaN and +Inf or -Inf values are ignored), and if there are fewer than four samples with numeric values for a feature, the IQR is set to be the difference between the highest and lowest of these.
- **Difference (original values).** For a two-group experiment the 'Difference' column contains the difference between the mean of the expression values across the samples assigned to

group 2 and the mean of the expression values across the samples assigned to group 1. Thus, if the mean expression level in group 2 is higher than that of group 1 the 'Difference' is positive, and if it is lower the 'Difference' is negative. For experiments with more than two groups the 'Difference' contains the difference between the maximum and minimum of the mean expression values of the groups, multiplied by -1 if the group with the maximum mean expression value occurs before the group with the minimum mean expression value (with the ordering: group 1, group 2, ...).

- **Fold Change (original values).** For a two-group experiment the 'Fold Change' tells you how many times bigger the mean expression value in group 2 is relative to that of group 1. If the mean expression value in group 2 is bigger than that in group 1 this value is the mean expression value in group 2 divided by that in group 1. If the mean expression value in group 2 is smaller than that in group 1 the fold change is the mean expression value in group 1 divided by that in group 2 with a negative sign. Thus, if the mean expression levels in group 1 and group 2 are 10 and 50 respectively, the fold change is 5, and if the and if the mean expression levels in group 1 and group 2 are 50 and 10 respectively, the fold change is -5. For experiments with more than two groups, the 'Fold Change' column contains the ratio of the maximum of the mean expression values of the groups to the minimum of the mean expression values of the groups, multiplied by -1 if the group with the maximum mean expression value occurs before the group with the minimum mean expression value (with the ordering: group 1, group 2, ...).

Thus, the sign of the values in the 'Difference' and 'Fold change' columns give the direction of the trend across the groups, going from group 1 to group 2, etc.

If the samples used are Affymetrix GeneChips samples and have 'Present calls' there will also be a 'Total present count' column containing the number of present calls for all samples.

The columns under the 'Experiment' header are useful for filtering purposes, e.g. you may wish to ignore features that differ too little in expression levels to be confirmed e.g. by qPCR by filtering on the values in the 'Difference', 'IQR' or 'Fold Change' columns or you may wish to ignore features that do not differ at all by filtering on the 'Range' column.

If you have performed normalization or transformation (see sections 20.2.3 and 20.2.2, respectively), the IQR of the normalized and transformed values will also appear. Also, if you later choose to transform or normalize your experiment, columns will be added for the transformed or normalized values.

Note! It is very common to filter features on fold change values in expression analysis and fold change values are also used in volcano plots, see section 20.4.4. There are different definitions of 'Fold Change' in the literature. The definition that is used typically depends on the original scale of the data that is analyzed. For data whose original scale is *not* the log scale the standard definition is the ratio of the group means [Tusher et al., 2001]. This is the value you find in the 'Fold Change' column of the experiment. However, for data whose original *is* the log scale, the difference of the mean expression levels is sometimes referred to as the fold change [Guo et al., 2006], and if you want to filter on fold change for these data you should filter on the values in the 'Difference' column. Your data's original scale will e.g. be the log scale if you have imported Affymetrix expression values which have been created by running the RMA algorithm on the probe-intensities.

Analysis level

If you perform statistical analysis (see section 20.4), there will be a heading for each statistical analysis performed. Under each of these headings you find columns holding relevant values for the analysis (P-value, corrected P-value, test-statistic etc. - see more in section 20.4).

An example of a more elaborate analysis level is shown in figure 20.7.

Figure 20.7: Transformation, normalization and statistical analysis has been performed.

Annotation level

If your experiment is annotated (see section 20.1.4), the annotations will be listed in the **Annotation level** group as shown in figure 20.8.

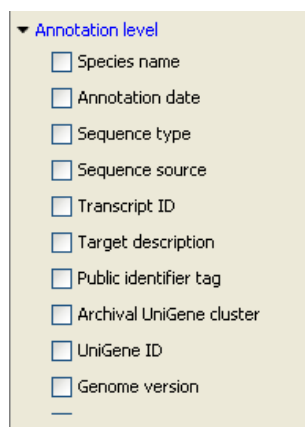

Figure 20.8: An annotated experiment.

In order to avoid too much detail and cluttering the table, only a few of the columns are shown per default.

Note that if you wish a different set of annotations to be displayed each time you open an experiment, you need to save the settings of the **Side Panel** (see section 5.6).

Group level

At the group level, you can show/hide entire groups (*Heart* and *Diaphragm* in figure 20.5). This will show/hide everything under the group's header. Furthermore, you can show/hide group-level information like the group means and present count within a group. If you have performed normalization or transformation (see sections 20.2.3 and 20.2.2, respectively), the means of the normalized and transformed values will also appear.

Sample level

In this part of the side panel, you can control which columns to be displayed for each sample. Initially this is the all the columns in the samples.

If you have performed normalization or transformation (see sections 20.2.3 and 20.2.2, respectively), the normalized and transformed values will also appear.

An example is shown in figure 20.9.

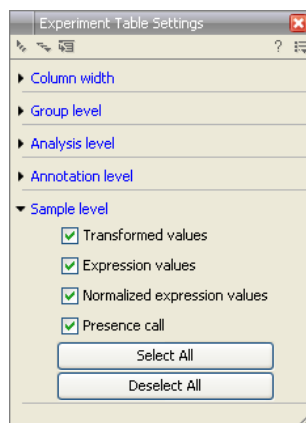

Figure 20.9: Sample level when transformation and normalization has been performed.

Creating a sub-experiment from a selection

If you have identified a list of genes that you believe are differentially expressed, you can create a subset of the experiment. (Note that the filtering and sorting may come in handy in this situation, see section C).

To create a sub-experiment, first select the relevant features (rows). If you have applied a filter and wish to select all the visible features, press **Ctrl + A** (⌘ + A on Mac). Next, press the **Create Experiment from Selection** (🗑️) button at the bottom of the table (see figure 20.10).

122,50	0,04	pre-mRNA p...	Prpf8	0000398 // ...	---	1.385,10	P

290,30	0,05	ubiquitin-lik...	Uba1	0006464 // ...	---	2.582,40	P
260,10	0,06	translocase ...	Tomm22	---	---	2.003,20	P

Figure 20.10: Create a subset of the experiment by clicking the button at the bottom of the experiment table.

This will create a new experiment that has the same information as the existing one but with less features.

Downloading sequences from the experiment table

If your experiment is annotated, you will be able to download the GenBank sequence for features which have a GenBank accession number in the 'Public identifier tag' annotation column. To do this, select a number of features (rows) in the experiment and then click **Download Sequence** (📄) (see figure 20.11).

122,60	0,04 pre-mRNA p...	Prpf8	0000398 // ...	---	1,385,10 P
453,40	0,05 lscU iron-su...	Iscu	0016226 // l...	---	3,561,60 P
480,60	0,25 SCAN domat...	Scand1_pre...	---	---	656,30 P
664,10	0,06 eukaryotic t...	Eif4g2_pred...	0006446 // ...	---	5,676,30 P
641,50	0,11 SAR1 gene ...	Sar1a	0006810 // ...	---	2,392,30 P
123,60	0,05 polymerase ...	Pokr2e	0006350 // ...	---	990,30 P
290,30	0,05 ubiquitin-lik...	Uba1	0006464 // ...	---	2,582,40 P
260,10	0,06 translocase ...	Tomm22	---	---	2,003,20 P

Figure 20.11: Select sequences and press the download button.

This will open a dialog where you specify where the sequences should be saved. You can learn more about opening and viewing sequences in chapter 11. You can now use the downloaded sequences for further analysis in the Workbench, e.g. performing BLAST searches and designing primers for QPCR experiments.

20.1.4 Adding annotations to an experiment

Annotation files provide additional information about each feature. This information could be which GO categories the protein belongs to, which pathways, various transcript and protein identifiers etc. See section K for information about the different annotation file formats that are supported *CLC Main Workbench*.

The annotation file can be imported into the Workbench and will get a special icon (📄). See an overview of annotation formats supported by *CLC Main Workbench* in section K. In order to associate an annotation file with an experiment, either select the annotation file when you set up the experiment (see section 20.1.2), or click:

Toolbox | Transcriptomics Analysis (📄) | Annotation Test | Add Annotations (📄)

Select the experiment (📄) and the annotation file (📄) and click **Finish**. You will now be able to see the annotations in the experiment as described in section 20.1.3. You can also add annotations by pressing the **Add Annotations** (📄) button at the bottom of the table (see figure 20.12).

122,60	0,04 pre-mRNA p...	Prpf8	0000398 // ...	---	1,385,10 P
453,40	0,05 lscU iron-su...	Iscu	0016226 // l...	---	3,561,60 P
480,60	0,25 SCAN domat...	Scand1_pre...	---	---	656,30 P
664,10	0,06 eukaryotic t...	Eif4g2_pred...	0006446 // ...	---	5,676,30 P
641,50	0,11 SAR1 gene ...	Sar1a	0006810 // ...	---	2,392,30 P
123,60	0,05 polymerase ...	Pokr2e	0006350 // ...	---	990,30 P
290,30	0,05 ubiquitin-lik...	Uba1	0006464 // ...	---	2,582,40 P
260,10	0,06 translocase ...	Tomm22	---	---	2,003,20 P

Figure 20.12: Adding annotations by clicking the button at the bottom of the experiment table.

This will bring up a dialog where you can select the annotation file that you have imported together with the experiment you wish to annotate. Click **Next** to specify settings as shown in figure 20.13).

Figure 20.13: Choosing how to match annotations with samples.

In this dialog, you can specify how to match the annotations to the features in the sample. The Workbench looks at the columns in the annotation file and lets you choose which column that should be used for matching to the feature IDs in the experimental data (samples or experiment). Usually the default is right, but for some annotation files, you need to use another column.

Some annotation files have leading zeros in the identifier which you can remove by checking the **Remove leading zeros** box.

Note! Existing annotations on the experiment will be overwritten.

20.1.5 Scatter plot view of an experiment

At the bottom of the experiment table, you can switch between different views of the experiment (see figure 20.14).

Figure 20.14: An experiment can be viewed in several ways.

One of the views is the **Scatter Plot** (📊). The scatter plot can be adjusted to show e.g. the group means for two groups (see more about how to adjust this below).

An example of a scatter plot is shown in figure 20.15.

In the **Side Panel** to the left, there are a number of options to adjust this view. Under **Graph preferences**, you can adjust the general properties of the scatter plot:

- **Lock axes.** This will always show the axes even though the plot is zoomed to a detailed level.
- **Frame.** Shows a frame around the graph.
- **Show legends.** Shows the data legends.
- **Tick type.** Determine whether tick lines should be shown outside or inside the frame.

Figure 20.15: A scatter plot of group means for two groups (transformed expression values).

- Outside
- Inside
- **Tick lines at.** Choosing Major ticks will show a grid behind the graph.
 - None
 - Major ticks
- **Horizontal axis range.** Sets the range of the horizontal axis (x axis). Enter a value in **Min** and **Max**, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.
- **Vertical axis range.** Sets the range of the vertical axis (y axis). Enter a value in **Min** and **Max**, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.
- **Draw $x = y$ axis.** This will draw a diagonal line across the plot. This line is shown per default.
- **Line width**
 - Thin
 - Medium
 - Wide
- **Line type**
 - None
 - Line
 - Long dash
 - Short dash

- **Line color.** Allows you to choose between many different colors. Click the color box to select a color.

Below the general preferences, you find the **Dot properties** preferences, where you can adjust coloring and appearance of the dots:

- **Dot type**
 - None
 - Cross
 - Plus
 - Square
 - Diamond
 - Circle
 - Triangle
 - Reverse triangle
 - Dot
- **Dot color.** Allows you to choose between many different colors. Click the color box to select a color.

Finally, the group at the bottom - **Columns to compare** - is where you choose the values to be plotted. Per default for a two-group experiment, the group means are used.

Note that if you wish to use the same settings next time you open a scatter plot, you need to save the settings of the **Side Panel** (see section 5.6).

20.1.6 Cross-view selections

There are a number of different ways of looking at an experiment as shown in figure 20.16).

Figure 20.16: An experiment can be viewed in several ways.

Beside the **Experiment table** (📊) which is the default view, the views are: **Scatter plot** (📈), **Volcano plot** (🌋) and the **Heat map** (🔥). By pressing and holding the Ctrl (⌘ on Mac) button while you click one of the view buttons in figure 20.16, you can make a split view. This will make it possible to see e.g. the experiment table in one view and the volcano plot in another view.

An example of such a split view is shown in figure 20.17.

Selections are shared between all these different views of an experiment. This means that if you select a number of rows in the table, the corresponding dots in the scatter plot, volcano plot or heatmap will also be selected. The selection can be made in any view, also the heatmap, and all other open views will reflect the selection.

Figure 20.17: A split view showing an experiment table at the top and a volcano plot at the bottom (note that you need to perform statistical analysis to show a volcano plot, see section 20.4).

A common use of the split views is where you have an experiment and have performed a statistical analysis. You filter the experiment to identify all genes that have an FDR corrected p-value below 0.05 and a fold change for the test above say, 2. You can select all the rows in the experiment table satisfying these filters by holding down the Cntrl button and clicking 'a'. If you have a split view of the experiment and the volcano plot all points in the volcano plot corresponding to the selected features will be red. Note that the volcano plot allows two sets of values in the columns under the test you are considering to be displayed on the x-axis: the 'Fold change's and the 'Difference's. You control which to plot in the side panel. If you have filtered on 'Fold change' you will typically want to choose 'Fold change' in the side panel. If you have filtered on 'Difference' (e.g. because your original data is on the log scale, see the note on fold change in 20.1.3) you typically want to choose 'Difference'.

20.2 Transformation and normalization

The original expression values often need to be transformed and/or normalized in order to ensure that samples are comparable and assumptions on the data for analysis are met [Allison et al., 2006]. These are essential requirements for carrying out a meaningful analysis. The raw expression values often exhibit a strong dependency of the variance on the mean, and it may be preferable to remove this by log-transforming the data. Furthermore, the sets of expression values in the different samples in an experiment may exhibit systematic differences that are likely due to differences in sample preparation and array processing, rather being the result of the underlying biology. These noise effects should be removed before statistical analysis is carried out.

When you perform transformation and normalization, the original expression values will be kept, and the new values will be added. If you select an experiment (📊), the new values will be added to the experiment (not the original samples). And likewise if you select a sample (📊) or (🇺🇸) - in this case the new values will be added to the sample (the original values are still kept on the sample).

20.2.1 Selecting transformed and normalized values for analysis

A number of the tools in the **Expression Analysis** (📊) folder use expression levels. All of these tools let you choose between *Original*, *Transformed* and *Normalized* expression values as shown in figure 20.18.

Figure 20.18: Selecting which version of the expression values to analyze. In this case, the values have not been normalized, so it is not possible to select normalized values.

In this case, the values have not been normalized, so it is not possible to select normalized values.

20.2.2 Transformation

The *CLC Main Workbench* lets you transform expression values based on logarithm and adding a constant:

Toolbox | Transcriptomics Analysis (📊) | Transformation and Normalization | Transform (📊)

Select a number of samples (📊) or (🇺🇸) or an experiment (📊) and click **Next**.

This will display a dialog as shown in figure 20.19.

At the top, you can select which values to transform (see section 20.2.1).

Next, you can choose three kinds of transformation:

- **Logarithm transformation.** Transformed expression values will be calculated by taking the logarithm (of the specified type) of the values you have chosen to transform.

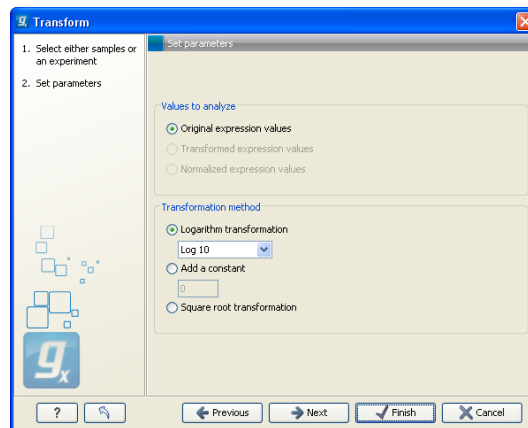

Figure 20.19: Transforming expression values.

- 10.
- 2.
- **Natural logarithm.**
- **Adding a constant.** Transformed expression values will be calculated by adding the specified constant to the values you have chosen to transform.
- **Square root transformation.**

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

20.2.3 Normalization

The *CLC Main Workbench* lets you normalize expression values.

To start the normalization:

Toolbox | Transcriptomics Analysis (📁) | Transformation and Normalization | Normalize (🔍)

Select a number of samples (📁) or (🇺🇸) or an experiment (📊) and click **Next**.

This will display a dialog as shown in figure 20.20.

At the top, you can choose three kinds of normalization (for mathematical descriptions see [Bolstad et al., 2003]):

- **Scaling.** The sets of the expression values for the samples will be multiplied by a constant so that the sets of normalized values for the samples have the same 'target' value (see description of the **Normalization value** below).
- **Quantile.** The empirical distributions of the sets of expression values for the samples are used to calculate a common target distribution, which is used to calculate normalized sets of expression values for the samples.
- **By totals.** This option is intended to be used with count-based data, i.e. data from RNA-seq, small RNA or expression profiling by tags. A sum is calculated for the expression values in a sample. The transformed value are generated by dividing the input values by the sample sum and multiplying by the factor (e.g. per '1,000,000').

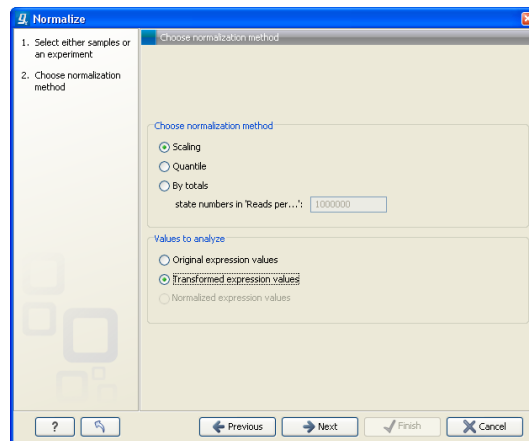

Figure 20.20: Choosing normalization method.

Figures 20.21 and 20.22 show the effect on the distribution of expression values when using scaling or quantile normalization, respectively.

Figure 20.21: Box plot after scaling normalization.

Figure 20.22: Box plot after quantile normalization.

At the bottom of the dialog in figure 20.20, you can select which values to normalize (see section 20.2.1).

Clicking **Next** will display a dialog as shown in figure 20.23.

The following parameters can be set:

- **Normalization value.** The type of value of the samples which you want to ensure are equal for the normalized expression values

– **Mean.**

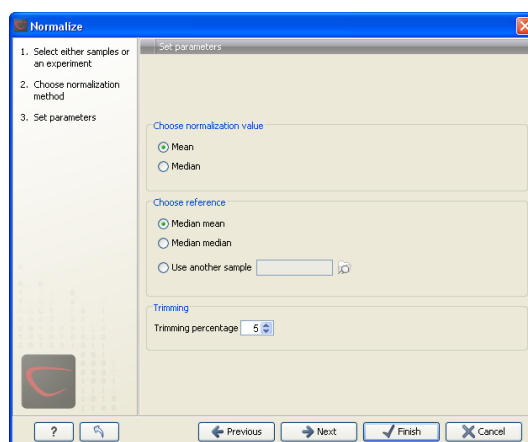

Figure 20.23: Normalization settings.

- **Median.**
- **Reference.** The specific value that you want the normalized value to be after normalization.
 - **Median mean.**
 - **Median median.**
 - **Use another sample.**
- **Trimming percentage.** Expression values that lie below the value of this percentile, or above 100 minus the value of this percentile, in the empirical distribution of the expression values in a sample will be excluded when calculating the normalization and reference values.

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

20.3 Quality control

The *CLC Main Workbench* includes a number of tools for quality control. These allow visual inspection of the overall distributions, variability and similarity of the sets of expression values in samples, and may be used to spot unwanted systematic differences between samples, outlying samples and samples of poor quality, that you may want to exclude.

20.3.1 Creating box plots - analyzing distributions

In most cases you expect the majority of genes to behave similarly under the conditions considered, and only a smaller proportion to behave differently. Thus, at an overall level you would expect the distributions of the sets of expression values in samples in a study to be similar. A boxplot provides a visual presentation of the distributions of expression values in samples. For each sample the distribution of its values is presented by a line representing a center, a box representing the middle part, and whiskers representing the tails of the distribution. Differences in the overall distributions of the samples in a study may indicate that normalization is required before the samples are comparable. An atypical distribution for a single sample (or a few samples), relative to the remaining samples in a study, could be due to imperfections in the preparation and processing of the sample, and may lead you to reconsider using the sample(s).

To create a box plot:

Toolbox | Transcriptomics Analysis (📁) | Quality Control | Create Box Plot (📊)

Select a number of samples (📁) or (🇺🇸🇩🇪) or an experiment (📊) and click **Next**.

This will display a dialog as shown in figure 20.24.

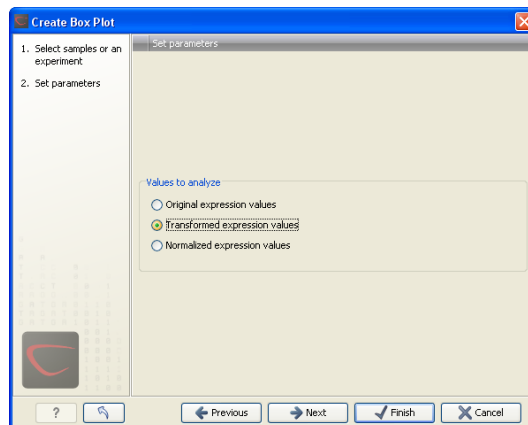

Figure 20.24: Choosing values to analyze for the box plot.

Here you select which values to use in the box plot (see section 20.2.1).

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

Viewing box plots

An example of a box plot of a two-group experiment with 12 samples is shown in figure 20.25.

Figure 20.25: A box plot of 12 samples in a two-group experiment, colored by group.

Note that the boxes per default are colored according to their group relationship. At the bottom you find the names of the samples, and the y-axis shows the expression values (note that sample names are not shown in figure 20.25).

Per default the box includes the IQR values (from the lower to the upper quartile), the median is displayed as a line in the box, and the whiskers extend 1.5 times the height of the box.

In the **Side Panel** to the left, there is a number of options to adjust this view. Under **Graph preferences**, you can adjust the general properties of the box plot (see figure 20.26).

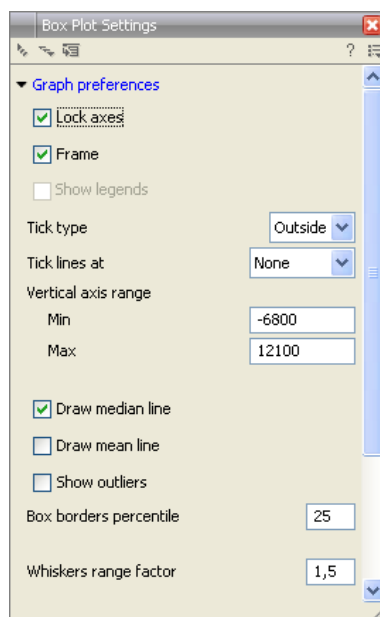

Figure 20.26: Graph preferences for a box plot.

- **Lock axes.** This will always show the axes even though the plot is zoomed to a detailed level.
- **Frame.** Shows a frame around the graph.
- **Show legends.** Shows the data legends.
- **Tick type.** Determine whether tick lines should be shown outside or inside the frame.
 - Outside
 - Inside
- **Tick lines at.** Choosing Major ticks will show a grid behind the graph.
 - None
 - Major ticks
- **Vertical axis range.** Sets the range of the vertical axis (y axis). Enter a value in **Min** and **Max**, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.
- **Draw median line.** This is the default - the median is drawn as a line in the box.
- **Draw mean line.** Alternatively, you can also display the mean value as a line.

- **Show outliers.** The values outside the whiskers range are called outliers. Per default they are not shown. Note that the dot type that can be set below only takes effect when outliers are shown. When you select and deselect the **Show outliers**, the vertical axis range is automatically re-calculated to accommodate the new values.

Below the general preferences, you find the **Lines and dots** preferences, where you can adjust coloring and appearance (see figure 20.27).

Figure 20.27: Lines and dot preferences for a box plot.

- **Select sample or group.** When you wish to adjust the properties below, first select an item in this drop-down menu. That will apply the changes below to this item. If your plot is based on an experiment, the drop-down menu includes both group names and sample names, as well as an entry for selecting "All". If your plot is based on single elements, only sample names will be visible. Note that there are sometimes "mixed states" when you select a group where two of the samples e.g. have different colors. Selecting a new color in this case will erase the differences.
- **Dot type**
 - None
 - Cross
 - Plus
 - Square
 - Diamond
 - Circle
 - Triangle
 - Reverse triangle
 - Dot
- **Dot color.** Allows you to choose between many different colors. Click the color box to select a color.

Note that if you wish to use the same settings next time you open a box plot, you need to save the settings of the **Side Panel** (see section 5.6).

Figure 20.28: Box plot for an experiment with 5 groups and 27 samples.

Interpreting the box plot

This section will show how to interpret a box plot through a few examples.

First, if you look at figure 20.28, you can see a box plot for an experiment with 5 groups and 27 samples.

None of the samples stand out as having distributions that are atypical: the boxes and whiskers ranges are about equally sized. The locations of the distributions however, differ some, and indicate that normalization may be required. Figure 20.29 shows a box plot for the same experiment after quantile normalization: the distributions have been brought into par.

Figure 20.29: Box plot after quantile normalization.

In figure 20.30 a box plot for a two group experiment with 5 samples in each group is shown.

The distribution of values in the second sample from the left is quite different from those of other samples, and could indicate that the sample should not be used.

20.3.2 Hierarchical clustering of samples

A hierarchical clustering of samples is a tree representation of their relative similarity. The tree structure is generated by

1. letting each feature be a cluster

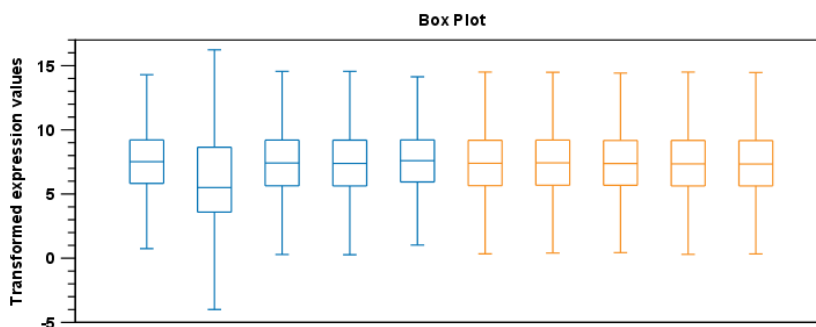

Figure 20.30: Box plot for a two-group experiment with 5 samples.

2. calculating pairwise distances between all clusters
3. joining the two closest clusters into one new cluster
4. iterating 2-3 until there is only one cluster left (which will contain all samples).

The tree is drawn so that the distances between clusters are reflected by the lengths of the branches in the tree. Thus, features with expression profiles that closely resemble each other have short distances between them, those that are more different, are placed further apart. (See [Eisen et al., 1998] for a classical example of application of a hierarchical clustering algorithm in microarray analysis. The example is on features rather than samples).

To start the clustering:

Toolbox | Transcriptomics Analysis (🇺🇸) | Quality Control | Hierarchical Clustering of Samples (🇺🇸)

Select a number of samples (🇺🇸) or (🇺🇸) or an experiment (🇺🇸) and click **Next**.

This will display a dialog as shown in figure 20.31. The hierarchical clustering algorithm requires that you specify a distance measure and a cluster linkage. The similarity measure is used to specify how distances between two samples should be calculated. The cluster distance metric specifies how you want the distance between two clusters, each consisting of a number of samples, to be calculated.

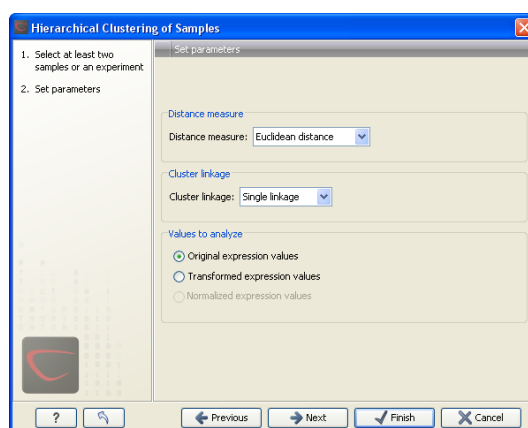

Figure 20.31: Parameters for hierarchical clustering of samples.

At the top, you can choose three kinds of **Distance measures**:

- **Euclidean distance.** The ordinary distance between two points - the length of the segment connecting them. If $u = (u_1, u_2, \dots, u_n)$ and $v = (v_1, v_2, \dots, v_n)$, then the Euclidean distance between u and v is

$$|u - v| = \sqrt{\sum_{i=1}^n (u_i - v_i)^2}.$$

- **1 - Pearson correlation.** The Pearson correlation coefficient between two elements $x = (x_1, x_2, \dots, x_n)$ and $y = (y_1, y_2, \dots, y_n)$ is defined as

$$r = \frac{1}{n-1} \sum_{i=1}^n \left(\frac{x_i - \bar{x}}{s_x} \right) * \left(\frac{y_i - \bar{y}}{s_y} \right)$$

where \bar{x}/\bar{y} is the average of values in x/y and s_x/s_y is the sample standard deviation of these values. It takes a value $\in [-1, 1]$. Highly correlated elements have a high absolute value of the Pearson correlation, and elements whose values are un-informative about each other have Pearson correlation 0. Using $1 - |Pearsoncorrelation|$ as distance measure means that elements that are highly correlated will have a short distance between them, and elements that have low correlation will be more distant from each other.

- **Manhattan distance.** The Manhattan distance between two points is the distance measured along axes at right angles. If $u = (u_1, u_2, \dots, u_n)$ and $v = (v_1, v_2, \dots, v_n)$, then the Manhattan distance between u and v is

$$|u - v| = \sum_{i=1}^n |u_i - v_i|.$$

Next, you can select the cluster linkage to be used:

- **Single linkage.** The distance between two clusters is computed as the distance between the two closest elements in the two clusters.
- **Average linkage.** The distance between two clusters is computed as the average distance between objects from the first cluster and objects from the second cluster. The averaging is performed over all pairs (x, y) , where x is an object from the first cluster and y is an object from the second cluster.
- **Complete linkage.** The distance between two clusters is computed as the maximal object-to-object distance $d(x_i, y_j)$, where x_i comes from the first cluster, and y_j comes from the second cluster. In other words, the distance between two clusters is computed as the distance between the two farthest objects in the two clusters.

At the bottom, you can select which values to cluster (see section 20.2.1).

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

Result of hierarchical clustering of samples

The result of a sample clustering is shown in figure 20.32.

Figure 20.32: Sample clustering.

Figure 20.33: Showing the hierarchical clustering of an experiment.

If you have used an **experiment** (📊) as input, the clustering is added to the experiment and will be saved when you save the experiment. It can be viewed by clicking the **Show Heat Map** (🔥) button at the bottom of the view (see figure 20.33).

If you have selected a number of **samples** (📄) or (🇺🇸) as input, a new element will be created that has to be saved separately.

Regardless of the input, the view of the clustering is the same. As you can see in figure 20.32, there is a tree at the bottom of the view to visualize the clustering. The names of the samples are listed at the top. The features are represented as horizontal lines, colored according to the expression level. If you place the mouse on one of the lines, you will see the names of the feature to the left. The features are sorted by their expression level in the first sample (in order to cluster the features, see section 20.5.1).

Researchers often have a priori knowledge of which samples in a study should be similar (e.g. samples from the same experimental condition) and which should be different (samples from biological distinct conditions). Thus, researchers have expectations about how they should cluster. Samples that are placed unexpectedly in the hierarchical clustering tree may be samples that have been wrongly allocated to a group, samples of unintended or unclear tissue composition or samples for which the processing has gone wrong. Unexpectedly placed samples, of course, could also be highly interesting samples.

There are a number of options to change the appearance of the heat map. At the top of the **Side Panel**, you find the **Heat map** preference group (see figure 20.34).

At the top, there is information about the heat map currently displayed. The information regards type of clustering, expression value used together with distance and linkage information. If you have performed more than one clustering, you can choose between the resulting heat maps in a drop-down box (see figure 20.46).

Note that if you perform an identical clustering, the existing heat map will simply be replaced. Below this box, there is a number of settings for displaying the heat map.

- **Lock width to window.** When you zoom in the heat map, you will per default only zoom in

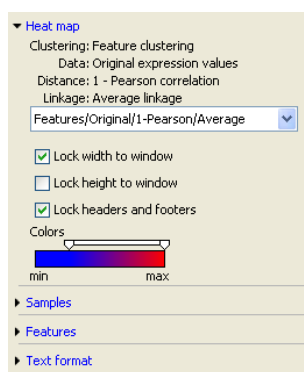

Figure 20.34: Side Panel of heat map.

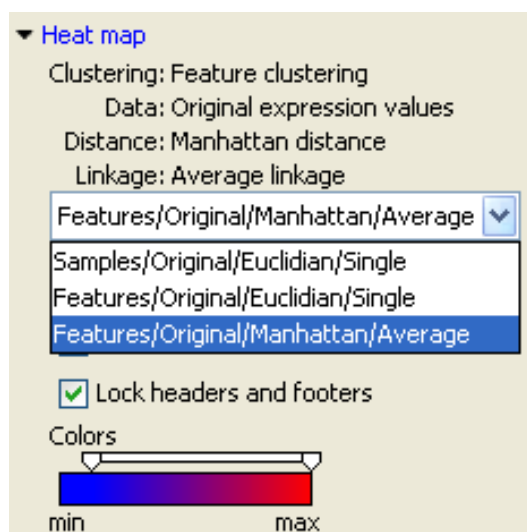

Figure 20.35: When more than one clustering has been performed, there will be a list of heat maps to choose from.

on the vertical level. This is because the width of the heat map is locked to the window. If you uncheck this option, you will zoom both vertically and horizontally. Since you always have more features than samples, it is useful to lock the width since you then have all the samples in view all the time.

- **Lock height to window.** This is the corresponding option for the height. Note that if you check both options, you will not be able to zoom at all, since both the width and the height is fixed.
- **Lock headers and footers.** This will ensure that you are always able to see the sample and feature names and the trees when you zoom in.
- **Colors.** The expression levels are visualized using a gradient color scheme, where the right side color is used for high expression levels and the left side color is used for low expression levels. You can change the coloring by clicking the box, and you can change the relative coloring of the values by dragging the two knobs on the white slider above.

Below you find the **Samples** and **Features** groups. They contain options to show names above/below and left/right, respectively. Furthermore, they contain options to show the tree above/below or left/right, respectively. Note that for clustering of samples, you find the tree

options in the **Samples** group, and for clustering of features, you find the tree options in the **Features** group. With the tree options, you can also control the **Tree size**, from tiny to very large, and the option of showing the full tree, no matter how much space it will use.

Note that if you wish to use the same settings next time you open a heat map, you need to save the settings of the **Side Panel** (see section 5.6).

20.3.3 Principal component analysis

A principal component analysis is a mathematical analysis that identifies and quantifies the directions of variability in the data. For a set of samples, e.g. an experiment, this can be done by finding the eigenvectors and eigenvalues of the covariance matrix of the samples. The eigenvectors are orthogonal. The first principal component is the eigenvector with the largest eigenvalue, and specifies the direction with the largest variability. The second principal component is the eigenvector with the second largest eigenvalue, and specifies the direction with the second largest variability. Similarly for the third, etc. The data can be projected onto the space spanned by the eigenvectors. A plot of the data in the space spanned by the first and second principal component will show a simplified version of the data with variability in other directions than the two major directions of variability ignored.

To start the analysis:

Toolbox | Transcriptomics Analysis (📊) | Quality Control | Principal Component Analysis (📊)

Select a number of samples (📊) or (📊) or an experiment (📊) and click **Next**.

This will display a dialog as shown in figure 20.36.

Figure 20.36: Selecting which values the principal component analysis should be based on.

In this dialog, you select the values to be used for the principal component analysis (see section 20.2.1).

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

Principal component analysis plot

This will create a principal component plot as shown in figure 20.37.

Figure 20.37: A principal component analysis colored by group.

The plot shows the projection of the samples onto the two-dimensional space spanned by the first and second principal component. (These are the orthogonal directions in which the data exhibits the largest and second-largest variability).

The plot in figure 20.37 is based on a two-group experiment. The group relationships are indicated by color. We expect the samples from within a group to exhibit less variability when compared, than samples from different groups. Thus samples should cluster according to groups and this is what we see. The PCA plot is thus helpful in identifying outlying samples and samples that have been wrongly assigned to a group.

In the **Side Panel** to the left, there is a number of options to adjust the view. Under **Graph preferences**, you can adjust the general properties of the plot.

- **Lock axes.** This will always show the axes even though the plot is zoomed to a detailed level.
- **Frame.** Shows a frame around the graph.
- **Show legends.** Shows the data legends.
- **Tick type.** Determine whether tick lines should be shown outside or inside the frame.
 - Outside
 - Inside
- **Tick lines at.** Choosing Major ticks will show a grid behind the graph.
 - None
 - Major ticks
- **Horizontal axis range.** Sets the range of the horizontal axis (x axis). Enter a value in **Min** and **Max**, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.

- **Vertical axis range.** Sets the range of the vertical axis (y axis). Enter a value in **Min** and **Max**, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.
- **y = 0 axis.** Draws a line where $y = 0$. Below there are some options to control the appearance of the line:
 - **Line width**
 - * Thin
 - * Medium
 - * Wide
 - **Line type**
 - * None
 - * Line
 - * Long dash
 - * Short dash
 - **Line color.** Allows you to choose between many different colors. Click the color box to select a color.

Below the general preferences, you find the **Dot properties**:

- **Select sample or group.** When you wish to adjust the properties below, first select an item in this drop-down menu. That will apply the changes below to this item. If your plot is based on an experiment, the drop-down menu includes both group names and sample names, as well as an entry for selecting "All". If your plot is based on single elements, only sample names will be visible. Note that there are sometimes "mixed states" when you select a group where two of the samples e.g. have different colors. Selecting a new color in this case will erase the differences.
- **Dot type**
 - None
 - Cross
 - Plus
 - Square
 - Diamond
 - Circle
 - Triangle
 - Reverse triangle
 - Dot
- **Dot color.** Allows you to choose between many different colors. Click the color box to select a color.
- **Show name.** This will show a label with the name of the sample next to the dot. Note that the labels quickly get crowded, so that is why the names are not put on per default.

Note that if you wish to use the same settings next time you open a principal component plot, you need to save the settings of the **Side Panel** (see section 5.6).

Scree plot

Besides the view shown in figure 20.37, the result of the principal component can also be viewed as a scree plot by clicking the **Show Scree Plot**  button at the bottom of the view. The scree plot shows the proportion of variation in the data explained by each of the principal components. The first principal component explains about 99 percent of the variability.

In the **Side Panel** to the left, there is a number of options to adjust the view. Under **Graph preferences**, you can adjust the general properties of the plot.

- **Lock axes.** This will always show the axes even though the plot is zoomed to a detailed level.
- **Frame.** Shows a frame around the graph.
- **Show legends.** Shows the data legends.
- **Tick type.** Determine whether tick lines should be shown outside or inside the frame.
 - Outside
 - Inside
- **Tick lines at.** Choosing Major ticks will show a grid behind the graph.
 - None
 - Major ticks
- **Horizontal axis range.** Sets the range of the horizontal axis (x axis). Enter a value in **Min** and **Max**, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.
- **Vertical axis range.** Sets the range of the vertical axis (y axis). Enter a value in **Min** and **Max**, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.

The **Lines and plots** below contains the following parameters:

- **Dot type**
 - None
 - Cross
 - Plus
 - Square
 - Diamond
 - Circle
 - Triangle
 - Reverse triangle
 - Dot
- **Dot color.** Allows you to choose between many different colors. Click the color box to select a color.

- **Line width**

- Thin
- Medium
- Wide

- **Line type**

- None
- Line
- Long dash
- Short dash

- **Line color.** Allows you to choose between many different colors. Click the color box to select a color.

Note that the graph title and the axes titles can be edited simply by clicking them with the mouse. These changes will be saved when you **Save** () the graph - whereas the changes in the **Side Panel** need to be saved explicitly (see section 5.6).

20.4 Statistical analysis - identifying differential expression

The *CLC Main Workbench* is designed to help you identify differential expression. You have a choice of a number of standard statistical tests, that are suitable for different data types and different types of experimental settings. There are two main categories of tests: tests that assume that the data has Gaussian distributions and compare means (described in section 20.4.1) and tests that compare proportions and assume that data consists of counts and (described in section 20.4.2). To run the statistical analysis:

Toolbox | Transcriptomics Analysis () | **Statistical Analysis | On Gaussian Data** ()

or **Toolbox | Transcriptomics Analysis** () | **Statistical Analysis | On Proportions** ()

For both kinds of statistics you first select the experiment () that you wish to use and click **Next** (learn more about setting up experiments in section 20.1.2).

The first part of the explanation of how to proceed and perform the statistical analysis is divided into two, depending on whether you are doing Gaussian-based tests or tests on proportions. The last part has an explanation of the options regarding corrected p-values which applies to all tests.

20.4.1 Gaussian-based tests

The tests based on the Gaussian distribution essentially compare the mean expression level in the experimental groups in the study, and evaluates the significance of the difference relative to the variance (or 'spread') of the data within the groups. The details of the formula used for calculating the test statistics vary according to the experimental setup and the assumptions you make about the data (read more about this in the sections on t-test and ANOVA below). The explanation of how to proceed is divided into two, depending on how many groups there are in your experiment. First comes the explanation for t-tests which is the only analysis available for

two-group experimental setups (t-tests can also be used for pairwise comparison of groups in multi-group experiments). Next comes an explanation of the ANOVA test which can be used for multi-group experiments.

Note that the test statistics for the t-test and ANOVA analysis use the estimated group variances in their denominators. If all expression values in a group are identical the estimated variance for that group will be zero. If the estimated variances for both (or all) groups are zero the denominator of the test statistic will be zero. The numerator's value depends on the difference of the group means. If this is zero, the numerator is zero and the test statistic will be 0/0 which is NaN. If the numerator is different from zero the test statistic will be + or - infinity, depending on which group mean is bigger. If all values in all groups are identical the test statistic is set to zero.

T-tests

For experiments with two groups you can, among the Gaussian tests, only choose a **T-test** as shown in figure 20.38.

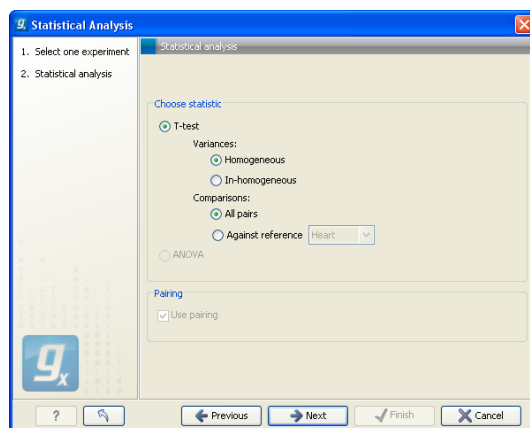

Figure 20.38: Selecting a t-test.

There are different types of t-tests, depending on the assumption you make about the variances in the groups. By selecting 'Homogeneous' (the default) calculations are done assuming that the groups have equal variances. When 'In-homogeneous' is selected, this assumption is not made.

The t-test can also be chosen if you have a multi-group experiment. In this case you may choose either to have t-tests produced for all pairs of groups (by clicking the 'All pairs' button) or to have a t-test produced for each group compared to a specified reference group (by clicking the 'Against reference' button). In the last case you must specify which of the groups you want to use as reference (the default is to use the group you specified as Group 1 when you set up the experiment).

If a experiment with pairing was set up (see section 20.1.2) the **Use pairing** tick box is active. If ticked, paired t-tests will be calculated, if not, the formula for the standard t-test will be used.

When a t-test is run on an experiment four columns will be added to the experiment table for each pair of groups that are analyzed. The 'Difference' column contains the difference between the mean of the expression values across the samples assigned to group 2 and the mean of the expression values across the samples assigned to group 1. The 'Fold Change' column tells you how many times bigger the mean expression value in group 2 is relative to that of group 1. If the mean expression value in group 2 is bigger than that in group 1 this value is the mean expression

value in group 2 divided by that in group 1. If the mean expression value in group 2 is smaller than that in group 1 the fold change is the mean expression value in group 1 divided by that in group 2 with a negative sign. The 'Test statistic' column holds that value of the test statistic, and the 'P-value' holds the two-sided p-value for the test. Up to two more columns may be added if the options to calculate Bonferroni and FDR corrected p-values were chosen (see 20.4.3).

ANOVA

For experiments with more than two groups you can choose **T-test** as described above, or **ANOVA** as shown in figure 20.39.

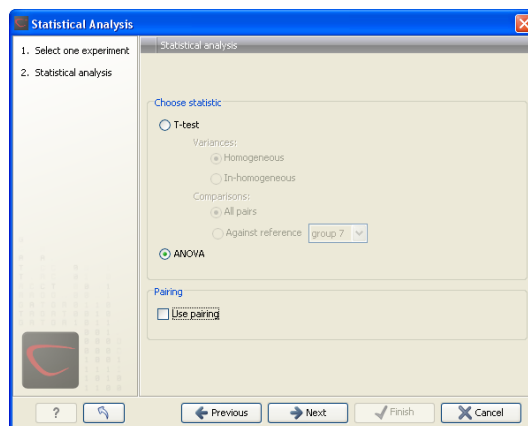

Figure 20.39: Selecting ANOVA.

The ANOVA method allows analysis of an experiment with one factor and a number of groups, e.g. different types of tissues, or time points. In the analysis, the variance within groups is compared to the variance between groups. You get a significant result (that is, a small ANOVA p-value) if the difference you see between groups relative to that within groups, is larger than what you would expect, if the data were really drawn from groups with equal means.

If an experiment with pairing was set up (see section 20.1.2) the **Use pairing** tick box is active. If ticked, a repeated measures one-way ANOVA test will be calculated, if not, the formula for the standard one-way ANOVA will be used.

When an ANOVA analysis is run on an experiment four columns will be added to the experiment table for each pair of groups that are analyzed. The 'Max difference' column contains the difference between the maximum and minimum of the mean expression values of the groups, multiplied by -1 if the group with the maximum mean expression value occurs before the group with the minimum mean expression value (with the ordering: group 1, group 2, ...). The 'Max fold change' column contains the ratio of the maximum of the mean expression values of the groups to the minimum of the mean expression values of the groups, multiplied by -1 if the group with the maximum mean expression value occurs before the group with the minimum mean expression value (with the ordering: group 1, group 2, ...). The 'Test statistic' column holds the value of the test statistic, and the 'P-value' holds the two-sided p-value for the test. Up to two more columns may be added if the options to calculate Bonferroni and FDR corrected p-values were chosen (see 20.4.3).

20.4.2 Tests on proportions

The proportions-based tests are applicable in situations where your data samples consists of counts of a number of 'types' of data. This could e.g. be in a study where gene expression levels are measured by RNA-Seq or tag profiling. Here the different 'types' could correspond to the different 'genes' in a reference genome, and the counts could be the numbers of reads matching each of these genes. The tests compare counts by considering the proportions that they make up the total sum of counts in each sample. By comparing the expression levels at the level of proportions rather than raw counts, the data is corrected for sample size.

There are two tests available for comparing proportions: the test of [Kal et al., 1999] and the test of [Baggerly et al., 2003]. Both tests compare pairs of groups. If you have a multi-group experiment (see section 20.1.2), you may choose either to have tests produced for all pairs of groups (by clicking the 'All pairs' button) or to have a test produced for each group compared to a specified reference group (by clicking the 'Against reference' button). In the last case you must specify which of the groups you want to use as reference (the default is to use the group you specified as Group 1 when you set up the experiment).

Note that the proportion-based tests use the total sample counts (that is, the sum over all expression values). If one (or more) of the counts are NaN, the sum will be NaN and all the test statistics will be NaN. As a consequence all p-values will also be NaN. You can avoid this by filtering your experiment and creating a new experiment so that no NaN values are present, before you apply the tests.

Kal et al.'s test (Z-test)

Kal et al.'s test [Kal et al., 1999] compares a single sample against another single sample, and thus requires that each group in you experiment has only one sample. The test relies on an approximation of the binomial distribution by the normal distribution [Kal et al., 1999]. Considering proportions rather than raw counts the test is also suitable in situations where the sum of counts is different between the samples.

When Kal's test is run on an experiment four columns will be added to the experiment table for each pair of groups that are analyzed. The 'Proportions difference' column contains the difference between the proportion in group 2 and the proportion in group 1. The 'Fold Change' column tells you how many times bigger the proportion in group 2 is relative to that of group 1. If the proportion in group 2 is bigger than that in group 1 this value is the proportion in group 2 divided by that in group 1. If the proportion in group 2 is smaller than that in group 1 the fold change is the proportion in group 1 divided by that in group 2 with a negative sign. The 'Test statistic' column holds that value of the test statistic, and the 'P-value' holds the two-sided p-value for the test. Up to two more columns may be added if the options to calculate Bonferroni and FDR corrected p-values were chosen (see 20.4.3).

Baggerley et al.'s test (Beta-binomial)

Baggerley et al.'s test [Baggerly et al., 2003] compares the proportions of counts in a group of samples against those of another group of samples, and is suited to cases where replicates are available in the groups. The samples are given different weights depending on their sizes (total counts). The weights are obtained by assuming a Beta distribution on the proportions in a group, and estimating these, along with the proportion of a binomial distribution, by the method

of moments. The result is a weighted t-type test statistic.

When Baggerley's test is run on an experiment four columns will be added to the experiment table for each pair of groups that are analyzed. The 'Weighted proportions difference' column contains the difference between the mean of the weighted proportions across the samples assigned to group 2 and the mean of the weighted proportions across the samples assigned to group 1. The 'Weighted proportions fold change' column tells you how many times bigger the mean of the weighted proportions in group 2 is relative to that of group 1. If the mean of the weighted proportions in group 2 is bigger than that in group 1 this value is the mean of the weighted proportions in group 2 divided by that in group 1. If the mean of the weighted proportions in group 2 is smaller than that in group 1 the fold change is the mean of the weighted proportions in group 1 divided by that in group 2 with a negative sign. The 'Test statistic' column holds that value of the test statistic, and the 'P-value' holds the two-sided p-value for the test. Up to two more columns may be added if the options to calculate Bonferroni and FDR corrected p-values were chosen (see 20.4.3).

20.4.3 Corrected p-values

Clicking **Next** will display a dialog as shown in figure 20.40.

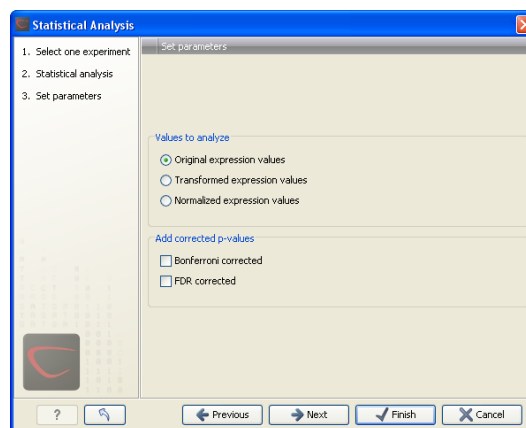

Figure 20.40: Additional settings for the statistical analysis.

At the top, you can select which values to analyze (see section 20.2.1).

Below you can select to add two kinds of corrected p-values to the analysis (in addition to the standard p-value produced for the test statistic):

- **Bonferroni corrected.**
- **FDR corrected.**

Both are calculated from the original p-values, and aim in different ways to take into account the issue of multiple testing [Dudoit et al., 2003]. The problem of multiple testing arises because the original p-values are related to a single test: the p-value is the probability of observing a more extreme value than that observed in the test carried out. If the p-value is 0.04, we would expect an as extreme value as that observed in 4 out of 100 tests carried out among groups with no difference in means. Popularly speaking, if we carry out 10000 tests and select the features with original p-values below 0.05, we will expect about 0.05 times 10000 = 500 to be false positives.

The Bonferroni corrected p-values handle the multiple testing problem by controlling the 'family-wise error rate': the probability of making at least one false positive call. They are calculated by multiplying the original p-values by the number of tests performed. The probability of having at least one false positive among the set of features with Bonferroni corrected p-values below 0.05, is less than 5%. The Bonferroni correction is conservative: there may be many genes that are differentially expressed among the genes with Bonferroni corrected p-values above 0.05, that will be missed if this correction is applied.

Instead of controlling the family-wise error rate we can control the false discovery rate: FDR. The false discovery rate is the proportion of false positives among all those declared positive. We expect 5 % of the features with FDR corrected p-values below 0.05 to be false positive. There are many methods for controlling the FDR - the method used in *CLC Main Workbench* is that of [Benjamini and Hochberg, 1995].

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

Note that if you have already performed statistical analysis on the same values, the existing one will be overwritten.

20.4.4 Volcano plots - inspecting the result of the statistical analysis

The results of the statistical analysis are added to the experiment and can be shown in the experiment table (see section 20.1.3). Typically columns containing the differences (or weighted differences) of the mean group values and the fold changes (or weighted fold changes) of the mean group values will be added along with a column of p-values. Also, columns with FDR or Bonferroni corrected p-values will be added if these were calculated. This added information allows features to be sorted and filtered to exclude the ones without sufficient proof of differential expression (learn more in section C).

If you want a more visual approach to the results of the statistical analysis, you can click the **Show Volcano Plot** (📊) button at the bottom of the experiment table view. In the same way as the scatter plot presented in section 20.1.5, the volcano plot is yet another view on the experiment. Because it uses the p-values and mean differences produced by the statistical analysis, the plot is only available once a statistical analysis has been performed on the experiment.

An example of a volcano plot is shown in figure 20.41.

The volcano plot shows the relationship between the p-values of a statistical test and the magnitude of the difference in expression values of the samples in the groups. On the y-axis the $-\log_{10}$ p-values are plotted. For the x-axis you may choose between two sets of values by choosing either 'Fold change' or 'Difference' in the volcano plot side panel's 'Values' part. If you choose 'Fold change' the log of the values in the 'fold change' (or 'Weighted fold change') column for the test will be displayed. If you choose 'Difference' the values in the 'Difference' (or 'Weighted difference') column will be used. Which values you wish to display will depend upon the scale of your data (Read the note on fold change in section 20.1.3).

The larger the difference in expression of a feature, the more extreme its point will lie on the X-axis. The more significant the difference, the smaller the p-value and thus the higher the $-\log_{10}(p)$ value. Thus, points for features with highly significant differences will lie high in the plot. Features of interest are typically those which change significantly and by a certain magnitude. These are the points in the upper left and upper right hand parts of the volcano plot.

Figure 20.41: *Volcano plot.*

If you have performed different tests or you have an experiment with multiple groups you need to specify for which test and which group comparison you want the volcano plot to be shown. You do this in the 'Test' and 'Values' parts of the volcano plot side panel.

Options for the volcano plot are described in further detail when describing the **Side Panel** below.

If you place your mouse on one of the dots, a small text box will tell the name of the feature. Note that you can zoom in and out on the plot (see section 3.2).

In the **Side Panel** to the right, there is a number of options to adjust the view of the volcano plot. Under **Graph preferences**, you can adjust the general properties of the volcano plot

- **Lock axes.** This will always show the axes even though the plot is zoomed to a detailed level.
- **Frame.** Shows a frame around the graph.
- **Show legends.** Shows the data legends.
- **Tick type.** Determine whether tick lines should be shown outside or inside the frame.
 - Outside
 - Inside
- **Tick lines at.** Choosing Major ticks will show a grid behind the graph.
 - None
 - Major ticks
- **Horizontal axis range.** Sets the range of the horizontal axis (x axis). Enter a value in **Min** and **Max**, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.

- **Vertical axis range.** Sets the range of the vertical axis (y axis). Enter a value in **Min** and **Max**, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.

Below the general preferences, you find the **Dot properties**, where you can adjust coloring and appearance of the dots.

- **Dot type**
 - None
 - Cross
 - Plus
 - Square
 - Diamond
 - Circle
 - Triangle
 - Reverse triangle
 - Dot
- **Dot color.** Allows you to choose between many different colors. Click the color box to select a color.

At the very bottom, you find two groups for choosing which values to display:

- **Test.** In this group, you can select which kind of test you want the volcano plot to be shown for.
- **Values.** Under **Values**, you can select which values to plot. If you have multi-group experiments, you can select which groups to compare. You can also select whether to plot **Difference** or **Fold change** on the x-axis. Read the note on fold change in section [20.1.3](#).

Note that if you wish to use the same settings next time you open a box plot, you need to save the settings of the **Side Panel** (see section [5.6](#)).

20.5 Feature clustering

Feature clustering is used to identify and cluster together features with similar expression patterns over samples (or experimental groups). Features that cluster together may be involved in the same biological process or be co-regulated. Also, by examining annotations of genes within a cluster, one may learn about the underlying biological processes involved in the experiment studied.

20.5.1 Hierarchical clustering of features

A hierarchical clustering of features is a tree presentation of the similarity in expression profiles of the features over a set of samples (or groups). The tree structure is generated by

1. letting each feature be a cluster
2. calculating pairwise distances between all clusters
3. joining the two closest clusters into one new cluster
4. iterating 2-3 until there is only one cluster left (which will contain all samples).

The tree is drawn so that the distances between clusters are reflected by the lengths of the branches in the tree. Thus, features with expression profiles that closely resemble each other have short distances between them, those that are more different, are placed further apart.

To start the clustering of features:

Toolbox | Transcriptomics Analysis (🇺🇸) | Feature Clustering | Hierarchical Clustering of Features (🇺🇸)

Select at least two samples (🇺🇸 or 🇺🇸) or an experiment (🇺🇸).

Note! If your data contains many features, the clustering will take very long time and could make your computer unresponsive. It is recommended to perform this analysis on a subset of the data (which also makes it easier to make sense of the clustering. Typically, you will want to filter away the features that are thought to represent only noise, e.g. those with mostly low values, or with little difference between the samples). See how to create a sub-experiment in section 20.1.3.

Clicking **Next** will display a dialog as shown in figure 20.42. The hierarchical clustering algorithm requires that you specify a distance measure and a cluster linkage. The distance measure is used specify how distances between two features should be calculated. The cluster linkage specifies how you want the distance between two clusters, each consisting of a number of features, to be calculated.

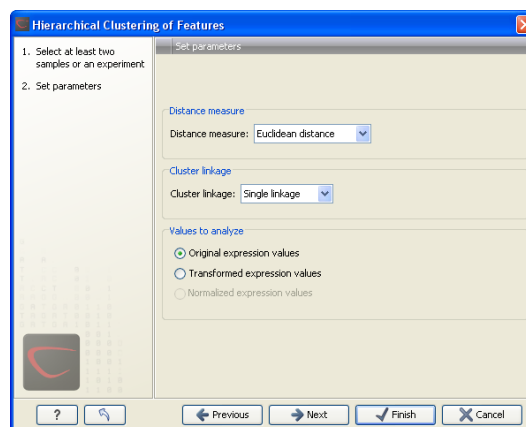

Figure 20.42: Parameters for hierarchical clustering of features.

At the top, you can choose three kinds of **Distance measures**:

- **Euclidean distance.** The ordinary distance between two points - the length of the segment connecting them. If $u = (u_1, u_2, \dots, u_n)$ and $v = (v_1, v_2, \dots, v_n)$, then the Euclidean distance between u and v is

$$|u - v| = \sqrt{\sum_{i=1}^n (u_i - v_i)^2}.$$

- **1 - Pearson correlation.** The Pearson correlation coefficient between two elements $x = (x_1, x_2, \dots, x_n)$ and $y = (y_1, y_2, \dots, y_n)$ is defined as

$$r = \frac{1}{n-1} \sum_{i=1}^n \left(\frac{x_i - \bar{x}}{s_x} \right) * \left(\frac{y_i - \bar{y}}{s_y} \right)$$

where \bar{x}/\bar{y} is the average of values in x/y and s_x/s_y is the sample standard deviation of these values. It takes a value $\in [-1, 1]$. Highly correlated elements have a high absolute value of the Pearson correlation, and elements whose values are un-informative about each other have Pearson correlation 0. Using $1 - |Pearsoncorrelation|$ as distance measure means that elements that are highly correlated will have a short distance between them, and elements that have low correlation will be more distant from each other.

- **Manhattan distance.** The Manhattan distance between two points is the distance measured along axes at right angles. If $u = (u_1, u_2, \dots, u_n)$ and $v = (v_1, v_2, \dots, v_n)$, then the Manhattan distance between u and v is

$$|u - v| = \sum_{i=1}^n |u_i - v_i|.$$

Next, you can select different ways to calculate distances between clusters. The possible cluster linkage to use are:

- **Single linkage.** The distance between two clusters is computed as the distance between the two closest elements in the two clusters.
- **Average linkage.** The distance between two clusters is computed as the average distance between objects from the first cluster and objects from the second cluster. The averaging is performed over all pairs (x, y) , where x is an object from the first cluster and y is an object from the second cluster.
- **Complete linkage.** The distance between two clusters is computed as the maximal object-to-object distance $d(x_i, y_j)$, where x_i comes from the first cluster, and y_j comes from the second cluster. In other words, the distance between two clusters is computed as the distance between the two farthest objects in the two clusters.

At the bottom, you can select which values to cluster (see section 20.2.1). Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

Result of hierarchical clustering of features

The result of a feature clustering is shown in figure 20.43.

If you have used an **experiment** () as input, the clustering is added to the experiment and will be saved when you save the experiment. It can be viewed by clicking the **Show Heat Map** () button at the bottom of the view (see figure 20.44).

If you have selected a number of **samples** () or () as input, a new element will be created that has to be saved separately.

Regardless of the input, a hierarchical tree view with associated heatmap is produced (figure 20.43). In the heatmap each row corresponds to a feature and each column to a sample. The

Figure 20.43: Hierarchical clustering of features.

Figure 20.44: Showing the hierarchical clustering of an experiment.

color in the i 'th row and j 'th column reflects the expression level of feature i in sample j (the color scale can be set in the side panel). The order of the rows in the heatmap are determined by the hierarchical clustering. If you place the mouse on one of the rows, you will see the name of the corresponding feature to the left. The order of the columns (that is, samples) is determined by their input order or (if defined) experimental grouping. The names of the samples are listed at the top of the heatmap and the samples are organized into groups.

There are a number of options to change the appearance of the heat map. At the top of the **Side Panel**, you find the **Heat map** preference group (see figure 20.45).

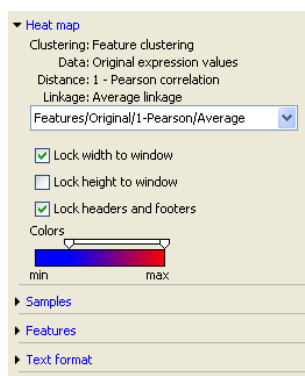

Figure 20.45: Side Panel of heat map.

At the top, there is information about the heat map currently displayed. The information regards type of clustering, expression value used together with distance and linkage information. If you have performed more than one clustering, you can choose between the resulting heat maps in a drop-down box (see figure 20.46).

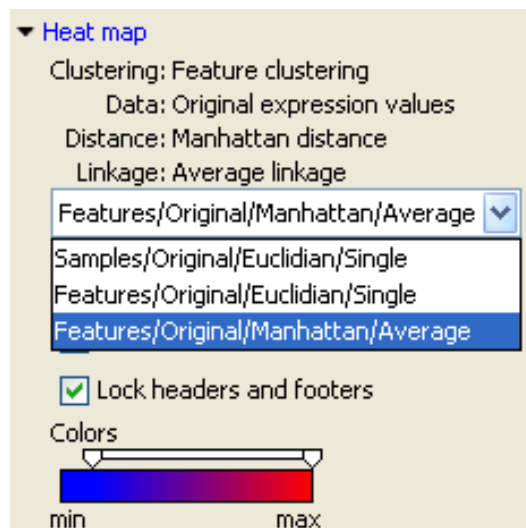

Figure 20.46: When more than one clustering has been performed, there will be a list of heat maps to choose from.

Note that if you perform an identical clustering, the existing heat map will simply be replaced. Below this box, there is a number of settings for displaying the heat map.

- **Lock width to window.** When you zoom in the heat map, you will per default only zoom in on the vertical level. This is because the width of the heat map is locked to the window. If you uncheck this option, you will zoom both vertically and horizontally. Since you always have more features than samples, it is useful to lock the width since you then have all the samples in view all the time.
- **Lock height to window.** This is the corresponding option for the height. Note that if you check both options, you will not be able to zoom at all, since both the width and the height is fixed.
- **Lock headers and footers.** This will ensure that you are always able to see the sample and feature names and the trees when you zoom in.
- **Colors.** The expression levels are visualized using a gradient color scheme, where the right side color is used for high expression levels and the left side color is used for low expression levels. You can change the coloring by clicking the box, and you can change the relative coloring of the values by dragging the two knobs on the white slider above.

Below you find the **Samples** and **Features** groups. They contain options to show names above/below and left/right, respectively. Furthermore, they contain options to show the tree above/below or left/right, respectively. Note that for clustering of samples, you find the tree options in the **Samples** group, and for clustering of features, you find the tree options in the **Features** group. With the tree options, you can also control the **Tree size**, from tiny to very large, and the option of showing the full tree, no matter how much space it will use.

Note that if you wish to use the same settings next time you open a heat map, you need to save the settings of the **Side Panel** (see section 5.6).

20.5.2 K-means/medoids clustering

In a k-means or medoids clustering, features are clustered into k separate clusters. The procedures seek to find an assignment of features to clusters, for which the distances between features within the cluster is small, while distances between clusters are large.

Toolbox | Transcriptomics Analysis (🇺🇸) | Feature Clustering | K-means/medoids Clustering (🇺🇸)

Select at least two samples (🇺🇸) or (🇺🇸) or an experiment (🇺🇸).

Note! If your data contains many features, the clustering will take very long time and could make your computer unresponsive. It is recommended to perform this analysis on a subset of the data (which also makes it easier to make sense of the clustering). See how to create a sub-experiment in section 20.1.3.

Clicking **Next** will display a dialog as shown in figure 20.47.

Figure 20.47: Parameters for k-means/medoids clustering.

The parameters are:

- **Algorithm.** You can choose between two clustering methods:
 - **K-means.** K-means clustering assigns each point to the cluster whose center is nearest. The center/centroid of a cluster is defined as the average of all points in the cluster. If a data set has three dimensions and the cluster has two points $X = (x_1, x_2, x_3)$ and $Y = (y_1, y_2, y_3)$, then the centroid Z becomes $Z = (z_1, z_2, z_3)$, where $z_i = (x_i + y_i)/2$ for $i = 1, 2, 3$. The algorithm attempts to minimize the intra-cluster variance defined by:

$$V = \sum_{i=1}^k \sum_{x_j \in S_i} (x_j - \mu_i)^2$$

where there are k clusters $S_i, i = 1, 2, \dots, k$ and μ_i is the centroid of all points $x_j \in S_i$. The detailed algorithm can be found in [Lloyd, 1982].

- **K-medoids.** K-medoids clustering is computed using the PAM-algorithm (PAM is short for Partitioning Around Medoids). It chooses datapoints as centers in contrast to the K-means algorithm. The PAM-algorithm is based on the search for k representatives

(called medoids) among all elements of the dataset. When having found k representatives k clusters are now generated by assigning each element to its nearest medoid. The algorithm first looks for a good initial set of medoids (the BUILD phase). Then it finds a local minimum for the objective function:

$$V = \sum_{i=1}^k \sum_{x_j \in S_i} (x_j - c_i)^2$$

where there are k clusters $S_i, i = 1, 2, \dots, k$ and c_i is the medoid of S_i . This solution implies that there is no single switch of an object with a medoid that will decrease the objective (this is called the SWAP phase). The PAM-algorithm is described in [Kaufman and Rousseeuw, 1990].

- **Number of partitions.** The number of partitions to cluster features into.
- **Distance metric.** The metric to compute distance between data points.
 - **Euclidean distance.** The ordinary distance between two elements - the length of the segment connecting them. If $u = (u_1, u_2, \dots, u_n)$ and $v = (v_1, v_2, \dots, v_n)$, then the Euclidean distance between u and v is

$$|u - v| = \sqrt{\sum_{i=1}^n (u_i - v_i)^2}.$$

- **Manhattan distance.** The Manhattan distance between two elements is the distance measured along axes at right angles. If $u = (u_1, u_2, \dots, u_n)$ and $v = (v_1, v_2, \dots, v_n)$, then the Manhattan distance between u and v is

$$|u - v| = \sum_{i=1}^n |u_i - v_i|.$$

- **Subtract mean value.** For each gene, subtract the mean gene expression value over all input samples.

Clicking **Next** will display a dialog as shown in figure 20.48.

Figure 20.48: Parameters for k -means/medoids clustering.

At the top, you can choose the **Level** to use. Choosing 'sample values' means that distances will be calculated using all the individual values of the samples. When 'group means' are chosen, distances are calculated using the group means.

At the bottom, you can select which values to cluster (see section 20.2.1).

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

Viewing the result of k-means/medoids clustering

The result of the clustering is a number of graphs. The number depends on the number of partitions chosen (figure 20.47) - there is one graph per cluster. Using drag and drop as explained in section 3.1.6, you can arrange the views to see more than one graph at the time.

Figure 20.49 shows an example where four clusters have been arranged side-by-side.

Figure 20.49: Four clusters created by k-means/medoids clustering.

The samples used are from a time-series experiment, and you can see that the expression levels for each cluster have a distinct pattern. The two clusters at the bottom have falling and rising expression levels, respectively, and the two clusters at the top both fall at the beginning but then

rise again (the one to the right starts to rise earlier than the other one).

Having inspected the graphs, you may wish to take a closer look at the features represented in each cluster. In the experiment table, the clustering has added an extra column with the name of the cluster that the feature belongs to. In this way you can filter the table to see only features from a specific cluster. This also means that you can select the feature of this cluster in a volcano or scatter plot as described in section 20.1.6.

20.6 Annotation tests

The annotation tests are tools for detecting significant patterns among features (e.g. genes) of experiments, based on their annotations. This may help in interpreting the analysis of the large numbers of features in an experiment in a biological context. Which biological context, depends on which annotation you choose to examine, and could e.g. be biological process, molecular function or pathway as specified by the Gene Ontology or KEGG. The annotation testing tools of course require that the features in the experiment you want to analyze are annotated. Learn how to annotate an experiment in section 20.1.4.

20.6.1 Hypergeometric tests on annotations

The first approach to using annotations to extract biological information is the hypergeometric annotation test. This test measures the extent to which the annotation categories of features in a smaller gene list, 'A', are over or under-represented relative to those of the features in larger gene list 'B', of which 'A' is a sub-list. Gene list B is often the features of the full experiment, possibly with features which are thought to represent only noise, filtered away. Gene list A is a sub-experiment of the full experiment where most features have been filtered away and only those that seem of interest are kept. Typically gene list A will consist of a list of candidate differentially expressed genes. This could be the gene list obtained after carrying out a statistical analysis on the experiment, and keeping only features with FDR corrected p-values <0.05 and a fold change which is larger than 2 in absolute value. The hypergeometric test procedure implemented is similar to the unconditional GOSTATS test of [Falcon and Gentleman, 2007].

Toolbox | Transcriptomics Analysis (📁) | Annotation Test | Hypergeometric Tests on Annotations (🌐)

This will show a dialog where you can select the two experiments - the larger experiment, e.g. the original experiment including the full list of features - and a sub-experiment (see how to create a sub-experiment in section 20.1.3).

Click **Next**. This will display the dialog shown in figure 20.50.

At the top, you select which annotation to use for testing. You can select from all the annotations available on the experiment, but it is of course only a few that are biologically relevant. Once you have selected an annotation, you will see the number of features carrying this annotation below.

Annotations are typically given at the gene level. Often a gene is represented by more than one feature in an experiment. If this is not taken into account it may lead to a biased result. The standard way to deal with this is to reduce the set of features considered, so that each gene is represented only once. In the next step, **Remove duplicates**, you can choose how you want this to be done:

Figure 20.50: Parameters for performing a hypergeometric test on annotations

- **Using gene identifier.**
- **Keep feature with:**
 - **Highest IQR.** The feature with the highest interquartile range (IQR) is kept.
 - **Highest value.** The feature with the highest expression value is kept.

First you specify which annotation you want to use as gene identifier. Once you have selected this, you will see the number of features carrying this annotation below. Next you specify which feature you want to keep for each gene. This may be either the feature with the highest inter-quartile range or the highest value.

At the bottom, you can select which values to analyze (see section 20.2.1).

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

Result of hypergeometric tests on annotations

The result of performing hypergeometric tests on annotations using GO biological process is shown in figure 20.51.

Category	Description	Full set	In subset	Expected i...	Observed ...	p-value

Figure 20.51: The result of testing on GO biological process.

The table shows the following information:

- **Category.** This is the identifier for the category.
- **Description.** This is the description belonging to the category. Both of these are simply extracted from the annotations.
- **Full set.** The number of features in the original experiment (not the subset) with this category. (Note that this is after removal of duplicates).
- **In subset.** The number of features in the the subset with this category. (Note that this is after removal of duplicates).
- **Expected in subset.** The number of features we would have expected to find with this annotation category in the subset, if the subset was a random draw from the full set.
- **Observed - expected.** 'In subset' - 'Expected in subset'
- **p-value.** The tail probability of the hyper geometric distribution This is the value used for sorting the table.

Categories with small p-values are categories that are over or under-represented on the features in the subset relative to the full set.

20.6.2 Gene set enrichment analysis

When carrying out a hypergeometric test on annotations you typically compare the annotations of the genes in a subset containing 'the significantly differentially expressed genes' to those of the total set of genes in the experiment. Which, and how many, genes are included in the subset is somewhat arbitrary - using a larger or smaller p-value cut-off will result in including more or less. Also, the magnitudes of differential expression of the genes is not considered.

The Gene Set Enrichment Analysis (GSEA) does NOT take a sublist of differentially expressed genes and compare it to the full list - it takes a single gene list (a single experiment). The idea behind GSEA is to consider a measure of association between the genes and phenotype of interest (e.g. test statistic for differential expression) and rank the genes according to this measure of association. A test is then carried out for each annotation category, for whether the ranks of the genes in the category are evenly spread throughout the ranked list, or tend to occur at the top or bottom of the list.

The GSEA test implemented here is that of [Tian et al., 2005]. The test implicitly calculates and uses a standard t-test statistic for two-group experiments, and ANOVA statistic for multiple group experiments for each feature, as measures of association. For each category, the test statistics for the features in than category are summed and a category based test statistic is calculated as this sum divided by the square root of the number of features in the category. Note that if a feature has the value NaN in one of the samples, the t-test statistic for the feature will be NaN. Consequently, the combined statistic for each of the categories in which the feature is included will be NaN. Thus, it is advisable to filter out any feature that has a NaN value before applying GSEA.

The p-values for the GSEA test statistics are calculated by permutation: The original test statistics for the features are permuted and new test statistics are calculated for each category, based on

the permuted feature test statistics. This is done the number of times specified by the user in the wizard. For each category, the lower and upper tail probabilities are calculated by comparing the original category test statistics to the distribution of the permutation-based test statistics for that category. The lower and higher tail probabilities are the number of these that are lower and higher, respectively, than the observed value, divided by the number of permutations.

As the p-values are based on permutations you may some times see results where category x's test statistic is lower than that of category y and the categories are of equal size, but where the lower tail probability of category x is higher than that of category y. This is due to imprecision in the estimations of the tail probabilities from the permutations. The higher the number of permutations, the more stable the estimation.

You may run a GSEA on a full experiment, or on a sub-experiment where you have filtered away features that you think are un-informative and represent only noise. Typically you will remove features that are constant across samples (those for which the value in the 'Range' column is zero' – these will have a t-test statistic of zero) and/or those for which the inter-quantile range is small. As the GSEA algorithm calculates and ranks genes on p-values from a test of differential expression, it will generally not make sense to filter the experiment on p-values produced in an analysis of differential expression, prior to running GSEA on it.

Toolbox | Transcriptomics Analysis () | Annotation Test | Gene Set Enrichment Analysis (GSEA) ()

Select an experiment and click **Next**.

Click **Next**. This will display the dialog shown in figure 20.52.

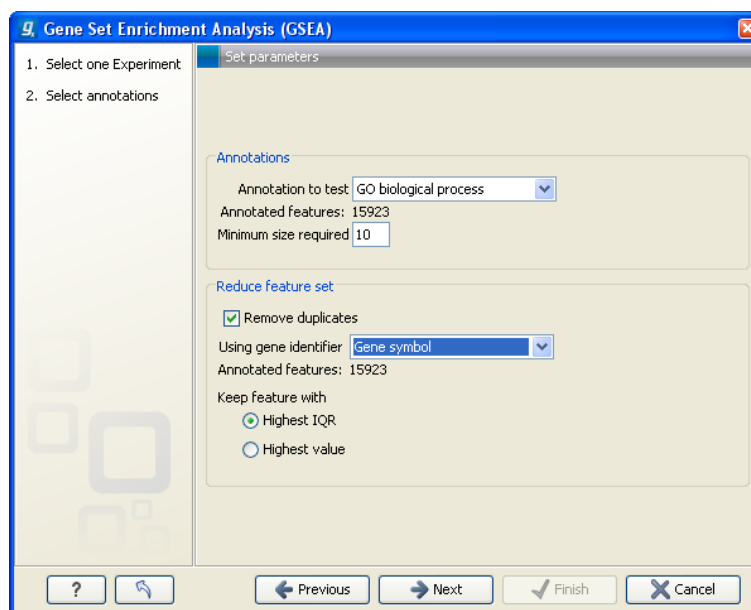

Figure 20.52: Gene set enrichment analysis on GO biological process

At the top, you select which annotation to use for testing. You can select from all the annotations available on the experiment, but it is of course only a few that are biologically relevant. Once you have selected an annotation, you will see the number of features carrying this annotation below.

In addition, you can set a filter: **Minimum size required**. Only categories with more genes (i.e. features) than the specified number will be considered. Excluding categories with small numbers

of genes may lead to more robust results.

Annotations are typically given at the gene level. Often a gene is represented by more than one feature in an experiment. If this is not taken into account it may lead to a biased result. The standard way to deal with this is to reduce the set of features considered, so that each gene is represented only once. Check the **Remove duplicates** check box to reduce the feature set, and you can choose how you want this to be done:

- **Using gene identifier.**
- **Keep feature with:**
 - **Highest IQR.** The feature with the highest interquartile range (IQR) is kept.
 - **Highest value.** The feature with the highest expression value is kept.

First you specify which annotation you want to use as gene identifier. Once you have selected this, you will see the number of features carrying this annotation below. Next you specify which feature you want to keep for each gene. This may be either the feature with the highest inter-quartile range or the highest value.

Clicking **Next** will display the dialog shown in figure 20.53.

Figure 20.53: Gene set enrichment analysis parameters.

At the top, you can select which values to analyze (see section 20.2.1).

Below, you can set the **Permutations for p-value calculation**. For the GSEA test a p-value is calculated by permutation: p permuted data sets are generated, each consisting of the original features, but with the test statistics permuted. The GSEA test is run on each of the permuted data sets. The test statistic is calculated on the original data, and the resulting value is compared to the distribution of the values obtained for the permuted data sets. The permutation based p-value is the number of permutation based test statistics above (or below) the value of the test statistic for the original data, divided by the number of permuted data sets. For reliable

permutation-based p-value calculation a large number of permutations is required (100 is the default).

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

Result of gene set enrichment analysis

The result of performing gene set enrichment analysis using GO biological process is shown in figure 20.54.

Figure 20.54: The result of gene set enrichment analysis on GO biological process.

The table shows the following information:

- **Category.** This is the identifier for the category.
- **Description.** This is the description belonging to the category. Both of these are simply extracted from the annotations.
- **Size.** The number of features with this category. (Note that this is after removal of duplicates).
- **Test statistic.** This is the GSEA test statistic.
- **Lower tail.** This is the mass in the permutation based p-value distribution below the value of the test statistic.
- **Upper tail.** This is the mass in the permutation based p-value distribution above the value of the test statistic.

A small lower (or upper) tail p-value for an annotation category is an indication that features in this category viewed as a whole are perturbed among the groups in the experiment considered.

20.7 General plots

The last folder in the **Expression Analysis** (📁) folder in the **Toolbox** is **General Plots**. Here you find three general plots that may be useful at various point of your analysis work flow. The plots

are explained in detail below.

20.7.1 Histogram

A histogram shows a distribution of a set of values. Histograms are often used for examining and comparing distributions, e.g. of expression values of different samples, in the quality control step of an analysis. You can create a histogram showing the distribution of expression value for a sample:

Toolbox | Transcriptomics Analysis (📁) | General Plots | Create Histogram (📊)

Select a number of samples (🇩🇪 or 🇺🇸). When you have selected more than one sample, a histogram will be created for each one. Clicking **Next** will display a dialog as shown in figure 20.55.

Figure 20.55: Selecting which values the histogram should be based on.

In this dialog, you select the values to be used for creating the histogram (see section 20.2.1). Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

Viewing histograms

The resulting histogram is shown in a figure 20.56

The histogram shows the expression value on the x axis (in the case of figure 20.56 the transformed expression values) and the counts of these values on the y axis.

In the **Side Panel** to the left, there is a number of options to adjust the view. Under **Graph preferences**, you can adjust the general properties of the plot.

- **Lock axes.** This will always show the axes even though the plot is zoomed to a detailed level.
- **Frame.** Shows a frame around the graph.
- **Show legends.** Shows the data legends.
- **Tick type.** Determine whether tick lines should be shown outside or inside the frame.
 - Outside

Figure 20.56: Histogram showing the distribution of transformed expression values.

- Inside
- **Tick lines at.** Choosing Major ticks will show a grid behind the graph.
 - None
 - Major ticks
- **Horizontal axis range.** Sets the range of the horizontal axis (x axis). Enter a value in **Min** and **Max**, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.
- **Vertical axis range.** Sets the range of the vertical axis (y axis). Enter a value in **Min** and **Max**, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.
- **Break points.** Determines where the bars in the histogram should be:
 - **Sturges method.** This is the default. The number of bars is calculated from the range of values by Sturges formula [Sturges, 1926].
 - **Equi-distanced bars.** This will show bars from **Start** to **End** and with a width of **Sep**.
 - **Number of bars.** This will simply create a number of bars starting at the lowest value and ending at the highest value.

Below the graph preferences, you find **Line color**. Allows you to choose between many different colors. Click the color box to select a color.

Note that if you wish to use the same settings next time you open a principal component plot, you need to save the settings of the **Side Panel** (see section 5.6).

Besides the histogram view itself, the histogram can also be shown in a table, summarizing key properties of the expression values. An example is shown in figure 20.57.

The table lists the following properties:

Data	Count
Number +Inf values	0
Number -Inf values	0
Number NaN values	0
Number values used	15923
Total number of values	15923

Figure 20.57: Table view of a histogram.

- **Number +Inf values**
- **Number -Inf values**
- **Number NaN values**
- **Number values used**
- **Total number of values**

20.7.2 MA plot

The MA plot is a scatter rotated by 45° . For two samples of expression values it plots for each gene the difference in expression against the mean expression level. MA plots are often used for quality control, in particular, to assess whether normalization and/or transformation is required.

You can create an MA plot comparing two samples:

Toolbox | Transcriptomics Analysis (📁) | General Plots | Create MA Plot (📄)

Select two samples (🇩🇪🇺🇸) or (🇩🇪🇺🇸). Clicking **Next** will display a dialog as shown in figure 20.58.

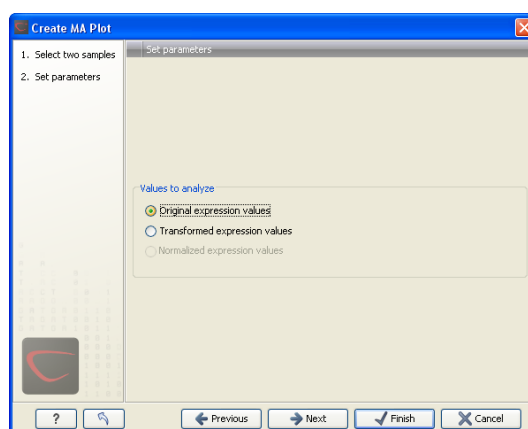

Figure 20.58: Selecting which values the MA plot should be based on.

In this dialog, you select the values to be used for creating the MA plot (see section 20.2.1).

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

Viewing MA plots

The resulting plot is shown in a figure 20.59.

Figure 20.59: MA plot based on original expression values.

The X axis shows the mean expression level of a feature on the two samples and the Y axis shows the difference in expression levels for a feature on the two samples. From the plot shown in figure 20.59 it is clear that the variance increases with the mean. With an MA plot like this, you will often choose to transform the expression values (see section 20.2.2).

Figure 20.60 shows the same two samples where the MA plot has been created using log2 transformed values.

Figure 20.60: MA plot based on transformed expression values.

The much more symmetric and even spread indicates that the dependence of the variance on the mean is not as strong as it was before transformation.

In the **Side Panel** to the left, there is a number of options to adjust the view. Under **Graph preferences**, you can adjust the general properties of the plot.

- **Lock axes.** This will always show the axes even though the plot is zoomed to a detailed level.
- **Frame.** Shows a frame around the graph.

- **Show legends.** Shows the data legends.
- **Tick type.** Determine whether tick lines should be shown outside or inside the frame.
 - Outside
 - Inside
- **Tick lines at.** Choosing Major ticks will show a grid behind the graph.
 - None
 - Major ticks
- **Horizontal axis range.** Sets the range of the horizontal axis (x axis). Enter a value in **Min** and **Max**, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.
- **Vertical axis range.** Sets the range of the vertical axis (y axis). Enter a value in **Min** and **Max**, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.
- **y = 0 axis.** Draws a line where $y = 0$. Below there are some options to control the appearance of the line:
 - **Line width**
 - * Thin
 - * Medium
 - * Wide
 - **Line type**
 - * None
 - * Line
 - * Long dash
 - * Short dash
 - **Line color.** Allows you to choose between many different colors. Click the color box to select a color.
- **Line width**
 - Thin
 - Medium
 - Wide
- **Line type**
 - None
 - Line
 - Long dash
 - Short dash
- **Line color.** Allows you to choose between many different colors. Click the color box to select a color.

Below the general preferences, you find the **Dot properties** preferences, where you can adjust coloring and appearance of the dots:

- **Dot type**

- None
- Cross
- Plus
- Square
- Diamond
- Circle
- Triangle
- Reverse triangle
- Dot

- **Dot color.** Allows you to choose between many different colors. Click the color box to select a color.

Note that if you wish to use the same settings next time you open a scatter plot, you need to save the settings of the **Side Panel** (see section 5.6).

20.7.3 Scatter plot

As described in section 20.1.5, an experiment can be viewed as a scatter plot. However, you can also create a "stand-alone" scatter plot of two samples:

Toolbox | Transcriptomics Analysis (📁) | General Plots | Create Scatter Plot (📊)

Select two samples (🇩🇪) or (🇺🇸). Clicking **Next** will display a dialog as shown in figure 20.61.

Figure 20.61: Selecting which values the scatter plot should be based on.

In this dialog, you select the values to be used for creating the scatter plot (see section 20.2.1).

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

For more information about the scatter plot view and how to interpret it, please see section 20.1.5.

CLC Main Workbench offers graphically advanced *in silico* cloning and design of vectors for various purposes together with restriction enzyme analysis and functionalities for managing lists of restriction enzymes.

First, after a brief introduction, restriction cloning and general vector design is explained. Next, we describe how to do Gateway Cloning ¹. Finally, the general restriction site analyses are described.

¹Gateway is a registered trademark of Invitrogen Corporation

21.1 Molecular cloning

Molecular cloning is a very important tool in the quest to understand gene function and regulation. Through molecular cloning it is possible to study individual genes in a controlled environment. Using molecular cloning it is possible to build complete libraries of fragments of DNA inserted into appropriate cloning vectors.

The *in silico* cloning process in *CLC Main Workbench* begins with the selection of sequences to be used:

Toolbox | Cloning and Restriction Sites (🔗) | Cloning (🔗)

This will open a dialog where you can select the sequences containing the fragments you want to clone (figure 21.1).

Figure 21.1: Selecting one or more sequences containing the fragments you want to clone.

Note that the vector sequence will be selected when you click **Next** as shown in figure figure 21.2.

Select the cloning vector by clicking the browse (🔗) button. Once the sequence has been selected, click **Finish**. The *CLC Main Workbench* will now create a sequence list of the fragments and vector sequences and open it in the cloning editor as shown in figure 21.3.

When you save the cloning experiment, it is saved as a **Sequence list**. See section 11.7 for more information about sequence lists. If you need to open the list later for cloning work, simply switch to the **Cloning** (🔗) editor at the bottom of the view.

If you later in the process need additional sequences, you can easily add more sequences to the

Figure 21.2: Selecting a cloning vector.

view. Just:

right-click anywhere on the empty white area | Add Sequences

21.1.1 Introduction to the cloning editor

In the cloning editor, most of the basic options for viewing, selecting and zooming the sequences are the same as for the standard sequence view. See section 11.1 for an explanation of these options. This means that e.g. known SNP's, exons and other annotations can be displayed on the sequences to guide the choice of regions to clone.

However, the cloning editor has a special layout with three distinct areas (in addition to the **Side Panel** found in other sequence views as well):

- At the top, there is a panel to switch between the sequences selected as input for the cloning. You can also specify whether the sequence should be visualized **as circular** or as a fragment. At the right-hand side, there is a button to the status of the sequence currently shown to **vector**.
- In the middle, the selected sequence is shown. This is the central area for defining how the cloning should be performed. This is explained in details below.
- At the bottom, there is a panel where the selection of fragments and target vector is performed (see elaboration below).

Figure 21.3: Cloning editor.

There are essentially three ways of performing cloning in the *CLC Main Workbench*. The *first* is the most straight-forward approach which is based on a simple model of selecting restriction sites for cutting out one or more fragments and defining how to open the vector to insert the fragments. This is described as *the cloning work flow* below. The *second* approach is unguided and more flexible and allows you to manually cut, copy, insert and replace parts of the sequences. This approach is described under *manual cloning* below. Finally, the *CLC Main Workbench* also supports *Gateway cloning* (see section 21.2).

21.1.2 The cloning work flow

The *cloning work flow* is designed to support restriction cloning work flows through the following steps:

1. Define one or more fragments
2. Define how the vector should be opened
3. Specify orientation and order of the fragment

Defining fragments

First, select the sequence containing the cloning fragment in the list at the top of the view. Next, make sure the restriction enzyme you wish to use is listed in the **Side Panel** (see section 21.3.1). To specify which part of the sequence should be treated as the fragment, first click one of the cut sites you wish to use. Then press and hold the Ctrl key (⌘ on Mac) while you click the second cut site. You can also right-click the cut sites and use the **Select This ... Site** to select a site.

When this is done, the panel below will update to reflect the selections (see figure 21.4).

In this example you can see that there are now three options listed in the panel below the view.

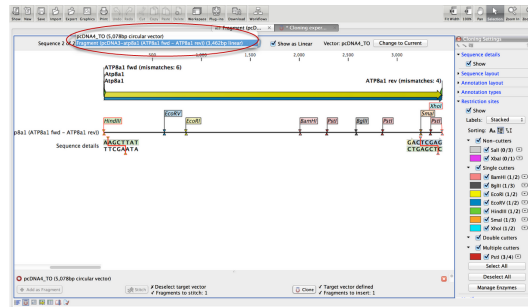

Figure 21.4: HindIII and XhoI cut sites selected to cut out fragment.

This is because there are now three options for selecting the fragment that should be used for cloning. The fragment selected per default is the one that is in between the cut sites selected.

If the entire sequence should be selected as fragment, click the **Add Current Sequence as Fragment (+)**.

At any time, the selection of cut sites can be cleared by clicking the **Remove (X)** icon to the right of the fragment selections. If you just wish to remove the selection of one of the sites, right-click the site on the sequence and choose **De-select This ... Site**.

Defining target vector

When selecting among the sequences in the panel at the top, the vector sequence has "vector" appended to its name. If you wish to use one of the other sequences as vector, select this sequence in the list and click **Change to Current**.

The next step is to define where the vector should be cut. If the vector sequence should just be opened, click the restriction site you want to use for opening. If you want to cut off part of the vector, click two restriction sites while pressing the Ctrl key (⌘ on Mac). You can also right-click the cut sites and use the **Select This ... Site** to select a site.

This will display two options for what the target vector should be (for linear vectors there would have been three option) as shown in figure 21.5)

Figure 21.5: HindIII and XhoI sites used to open the vector.

Just as when cutting out the fragment, there is a lot of choices regarding which sequence should

be used as the vector.

At any time, the selection of cut sites can be cleared by clicking the **Remove** (✖) icon to the right of the target vector selections. If you just wish to remove the selection of one of the sites, right-click the site on the sequence and choose **De-select This ... Site**.

When the right target vector is selected, you are ready to **Perform Cloning** (🔗), see below.

The cloning editor

The cloning editor can be activated in different ways. One way is to click on the **Cloning Editor** icon (🔗) in the view area when a sequence list has been opened in the sequence list editor. Another way is to create a new cloning experiment (the actual data object will still be a sequence list) using the **Cloning** (🔗) action from the toolbox. Using this action the user collects a set of existing sequences and creates a new sequence list.

The cloning editor can be used in two different ways:

1. **The cloning mode** is utilized when the user has selected one of the sequences as 'Vector'. In the cloning mode, the user opens up the vector by applying one or more cuts to the vector, thereby creating an opening for insertion of other sequence fragments. From the remaining sequences in the cloning experiment/sequence list, either complete sequences or fragments created by cutting can be inserted into the vector. In the cloning adapter dialog, the user can switch the order of the inserted fragments and rotate them prior to adjusting the overhangs to match the cloning conditions.
2. **The stitch mode** is utilized when the user deselects or has not selected a sequence as 'Vector'. In stitch mode, the user can select a number of fragments (either full sequences or cuttings) from the cloning experiment. These fragments can then be stitched together into one single new and longer sequence. In the stitching adapter dialog, the user can switch order and rotate the fragments prior to adjusting the overhangs to match the stitch conditions.

Perform cloning

Once selections have been made for both fragments and vector, click **Perform Cloning** (🔗). This will display a dialog to adapt overhangs and change orientation as shown in figure 21.6)

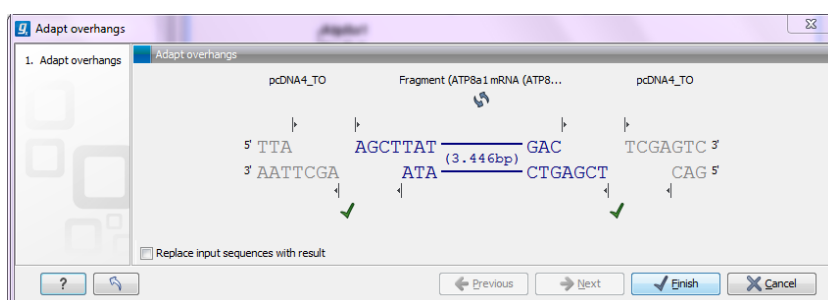

Figure 21.6: Showing the insertion point of the vector.

This dialog visualizes the details of the insertion. The vector sequence is on each side shown in a faded gray color. In the middle the fragment is displayed. If the overhangs of the sequence and

the vector do not match, you can blunt end or fill in the overhangs using the **drag handles** (↔). Click and drag with the mouse to adjust the overhangs.

Whenever you drag the handles, the status of the insertion point is indicated below:

- The overhangs match (✓).
- The overhangs do not match (⊘). In this case, you will not be able to click **Finish**. Drag the handles to make the overhangs match.

The fragment can be reverse complemented by clicking the **Reverse complement fragment** (↺).

When several fragments are used, the order of the fragments can be changed by clicking the move buttons (→)/ (←).

There is an option for the result of the cloning: **Replace input sequences with result**. Per default, the construct will be opened in a new view and can be saved separately. By selecting this option, the construct will also be added to the input sequence list and the original fragment and vector sequences will be deleted.

When you click **Finish** the final construct will be shown (see figure 21.7).

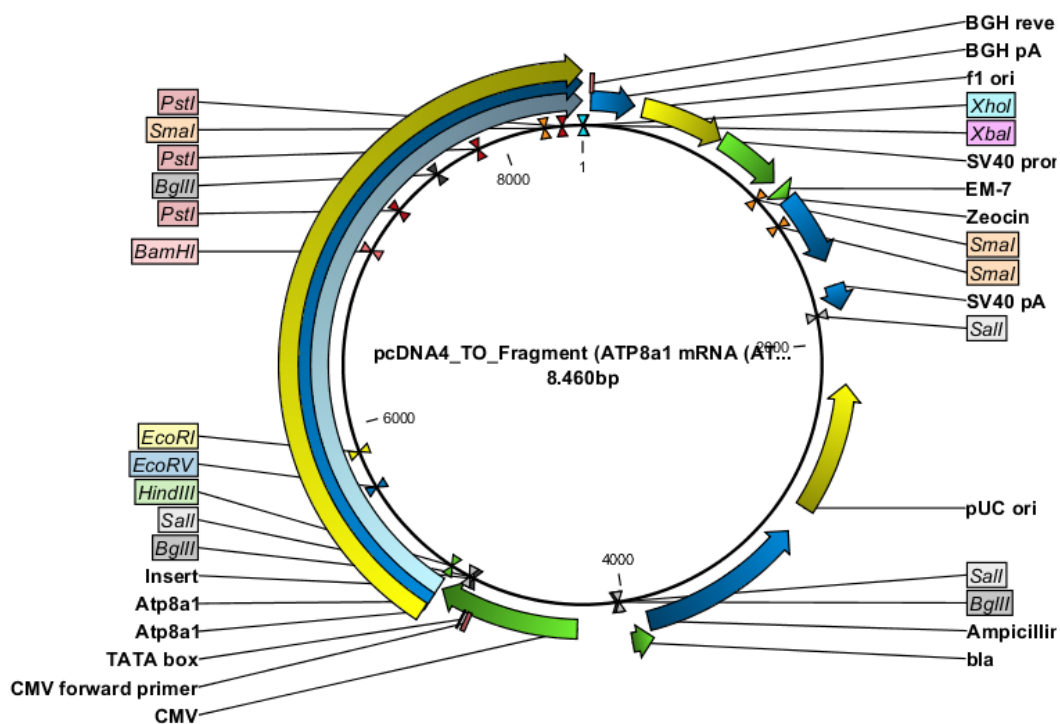

Figure 21.7: The final construct.

You can now **Save** (💾) this sequence for later use. The cloning experiment used to design the construct can be saved as well. If you check the **History** (📖) of the construct, you can see the details about restriction sites and fragments used for the cloning.

21.1.3 Manual cloning

If you wish to use the manual way of cloning (as opposed to using the cloning work flow explained above in section 21.1.2), you can disregard the panel at the bottom. The manual cloning approach is based on a number of ways that you can manipulate the sequences. All manipulations of sequences are done manually, giving you full control over how the final construct is made. Manipulations are performed through right-click menus, which have three different appearances depending on where you click, as visualized in figure 21.8.

Figure 21.8: The red circles mark the two places you can use for manipulating the sequences.

- **Right-click the sequence name (to the left) to manipulate the whole sequence.**
- **Right-click a selection to manipulate the selection.**

The two menus are described in the following:

Manipulate the whole sequence

Right-clicking the sequence name at the left side of the view reveals several options on sorting, opening and editing the sequences in the view (see figure 21.9).

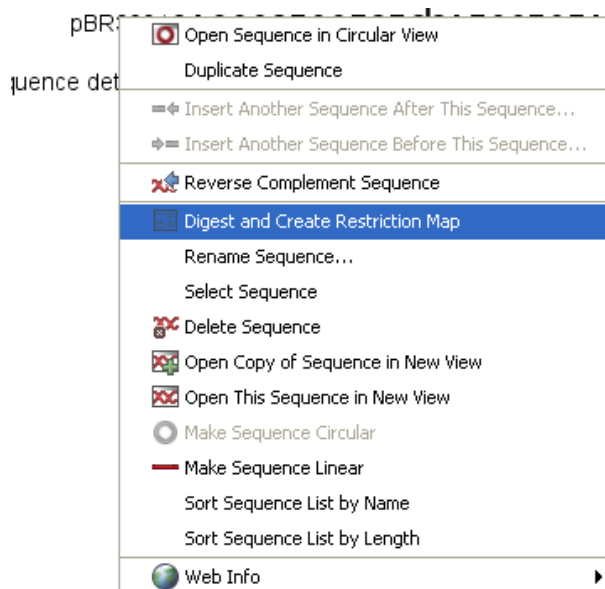

Figure 21.9: Right click on the sequence in the cloning view.

- **Open sequence in circular view (🗄)**
Opens the sequence in a new circular view. If the sequence is not circular, you will be asked

if you wish to make it circular or not. (This will not forge ends with matching overhangs together - use "Make Sequence Circular" () instead.)

- **Duplicate sequence**
Adds a duplicate of the selected sequence. The new sequence will be added to the list of sequences shown on the screen.
- **Insert sequence after this sequence** ()
Insert another sequence after this sequence. The sequence to be inserted can be selected from a list which contains the sequences present in the cloning editor. The inserted sequence remains on the list of sequences. If the two sequences do not have blunt ends, the ends' overhangs have to match each other. Otherwise a warning is displayed.
- **Insert sequence before this sequence** ()
Insert another sequence before this sequence. The sequence to be inserted can be selected from a list which contains the sequences present in the cloning editor. The inserted sequence remains on the list of sequences. If the two sequences do not have blunt ends, the ends' overhangs have to match each other. Otherwise a warning is displayed.
- **Reverse sequence**
Reverse the sequence and replaces the original sequence in the list. This is sometimes useful when working with single stranded sequences. Note that this is *not* the same as creating the reverse *complement* (see the following item in the list).
- **Reverse complement sequence** ()
Creates the reverse complement of a sequence and replaces the original sequence in the list. This is useful if the vector and the insert sequences are not oriented the same way.
- **Digest Sequence with Selected Enzymes and Run on Gel** ()
See section [21.4.1](#)
- **Rename sequence**
Renames the sequence.
- **Select sequence**
This will select the entire sequence.
- **Delete sequence** ()
This deletes the given sequence from the cloning editor.
- **Open sequence** ()
This will open the selected sequence in a normal sequence view.
- **Make sequence circular** ()
This will convert a sequence from a linear to a circular form. If the sequence have matching overhangs at the ends, they will be merged together. If the sequence have incompatible overhangs, a dialog is displayed, and the sequence cannot be made circular. The circular form is represented by >> and << at the ends of the sequence.
- **Make sequence linear** ()
This will convert a sequence from a circular to a linear form, removing the << and >> at the ends.

Manipulate parts of the sequence

Right-clicking a selection reveals several options on manipulating the selection (see figure 21.10).

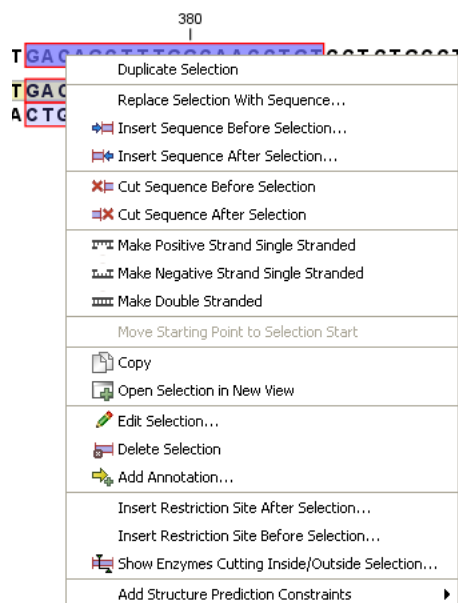

Figure 21.10: Right click on a sequence selection in the cloning view.

- **Replace Selection with sequence.** This will replace the selected region with a sequence. The sequence to be inserted can be selected from a list containing all sequences in the cloning editor.
- **Insert Sequence before Selection** (➡|). Insert a sequence before the selected region. The sequence to be inserted can be selected from a list containing all sequences in the cloning editor.
- **Insert Sequence after Selection** (|➡). Insert a sequence after the selected region. The sequence to be inserted can be selected from a list containing all sequences in the cloning editor.
- **Cut Sequence before Selection** (✕|). This will cleave the sequence before the selection and will result in two smaller fragments.
- **Cut Sequence after Selection** (|✕). This will cleave the sequence after the selection and will result in two smaller fragments.
- **Make Positive Strand Single Stranded** (☰). This will make the positive strand of the selected region single stranded.
- **Make Negative Strand Single Stranded** (☷). This will make the negative strand of the selected region single stranded.
- **Make Double Stranded** (☐). This will make the selected region double stranded.
- **Move Starting Point to Selection Start.** This is only active for circular sequences. It will move the starting point of the sequence to the beginning of the selection.

- **Copy Selection** (📄). This will copy the selected region to the clipboard, which will enable it for use in other programs.
- **Duplicate Selection**. If a selection on the sequence is duplicated, the selected region will be added as a new sequence to the cloning editor with a new sequence name representing the length of the fragment. When a sequence region between two restriction sites are double-clicked the entire region will automatically be selected. This makes it very easy to make a new sequence from a fragment created by cutting with two restriction sites (right-click the selection and choose **Duplicate selection**).
- **Open Selection in New View** (📄+). This will open the selected region in the normal sequence view.
- **Edit Selection** (✏️). This will open a dialog box, in which is it possible to edit the selected residues.
- **Delete Selection** (🗑️). This will delete the selected region of the sequence.
- **Add Annotation** (📌). This will open the **Add annotation** dialog box.
- **Show Enzymes Only Cutting Selection** (🔪). This will add enzymes cutting this selection to the Side Panel.
- **Insert Restriction Sites before/after Selection**. This will show a dialog where you can choose from a list restriction enzymes (see section 21.1.4).

Insert one sequence into another

Sequences can be inserted into each other in several ways as described in the lists above. When you chose to insert one sequence into another you will be presented with a dialog where all sequences in the view are present (see figure 21.11).

Figure 21.11: Select a sequence for insertion.

The sequence that you have chosen to insert into will be marked with **bold** and the text **[vector]** is appended to the sequence name. Note that this is completely unrelated to the vector concept in the cloning work flow described in section 21.1.2.

The list furthermore includes the length of the fragment, an indication of the overhangs, and a list of enzymes that are compatible with this overhang (for the left and right ends, respectively).

If not all the enzymes can be shown, place your mouse cursor on the enzymes, and a full list will be shown in the tool tip.

Select the sequence you wish to insert and click **Next**.

This will show the dialog in figure 21.12).

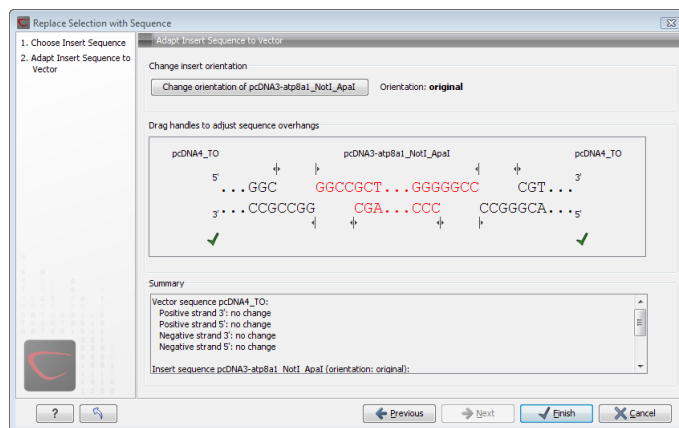

Figure 21.12: Drag the handles to adjust overhangs.

At the top is a button to reverse complement the inserted sequence.

Below is a visualization of the insertion details. The inserted sequence is at the middle shown in red, and the vector has been split at the insertion point and the ends are shown at each side of the inserted sequence.

If the overhangs of the sequence and the vector do not match, you can blunt end or fill in the overhangs using the **drag handles** (↔).

Whenever you drag the handles, the status of the insertion point is indicated below:

- The overhangs match (✓).
- The overhangs do not match (⊘). In this case, you will not be able to click **Finish**. Drag the handles to make the overhangs match.

At the bottom of the dialog is a summary field which records all the changes made to the overhangs. This contents of the summary will also be written in the history (📖) when you click **Finish**.

When you click **Finish** and the sequence is inserted, it will be marked with a selection.

Figure 21.13: One sequence is now inserted into the cloning vector. The sequence inserted is automatically selected.

21.1.4 Insert restriction site

If you make a selection on the sequence, right-click, you find this option for inserting the recognition sequence of a restriction enzyme before or after the region you selected. This will display a dialog as shown in figure 21.14

Figure 21.14: Inserting the *HindIII* recognition sequence.

At the top, you can select an existing enzyme list or you can use the full list of enzymes (default). Select an enzyme, and you will see its recognition sequence in the text field below the list (AAGCTT). If you wish to insert additional residues such as tags etc., this can be typed into the text fields adjacent to the recognition sequence. .

Click **OK** will insert the sequence before or after the selection. If the enzyme selected was not already present in the list in the **Side Panel**, it will now be added and selected. Furthermore, a restriction site annotation is added.

21.2 Gateway cloning

CLC Main Workbench offers tools to perform *in silico* Gateway cloning², including Multi-site Gateway cloning.

The three tools for doing Gateway cloning in the *CLC Main Workbench* mimic the procedure followed in the lab:

- First, attB sites are added to a sequence fragment
- Second, the attB-flanked fragment is recombined into a donor vector (the BP reaction) to construct an entry clone
- Finally, the target fragment from the entry clone is recombined into an expression vector (the LR reaction) to construct an expression clone. For Multi-site gateway cloning, multiple entry clones can be created that can recombine in the LR reaction.

²Gateway is a registered trademark of Invitrogen Corporation

During this process, both the attB-flanked fragment and the entry clone can be saved.

For more information about the Gateway technology, please visit <http://www.invitrogen.com/site/us/en/home/Products-and-Services/Applications/Cloning/Gateway-Cloning.html>

To perform these analyses in the *CLC Main Workbench*, you need to import donor and expression vectors. These can be downloaded from Invitrogen's web site and directly imported into the Workbench: <http://tools.invitrogen.com/downloads/Gateway%20vectors.ma4>

21.2.1 Add attB sites

The first step in the Gateway cloning process is to amplify the target sequence with primers including so-called attB sites. In the *CLC Main Workbench*, you can add attB sites to a sequence fragment in this way:

Toolbox in the Menu Bar | Cloning and Restriction Sites (🔗) | Gateway Cloning (📁) | Add attB Sites (🔗)

This will open a dialog where you can select on or more sequences. Note that if your fragment is part of a longer sequence, you need to extract it first. This can be done in two ways:

- If the fragment is covered by an annotation (if you want to use e.g. a CDS), simply right-click the annotation and **Open Annotation in New View**
- Otherwise you can simply make a selection on the sequence, right-click and **Open Selection in New View**

In both cases, the selected part of the sequence will be copied and opened as a new sequence which can be **Saved** (📁).

When you have selected your fragment(s), click **Next**.

This will allow you to choose which attB sites you wish to add to each end of the fragment as shown in figure 21.15.

The default option is to use the attB1 and attB2 sites. If you have selected several fragments and wish to add different combinations of sites, you will have to run this tool once for each combination.

Click **Next** will give you options to extend the fragment with additional sequences by extending the primers 5' of the template-specific part of the primer (i.e. between the template specific part and the attB sites). See an example of this in figure 21.21 where a Shine-Dalgarno site has been added between the attB site and the gene of interest.

At the top of the dialog (see figure 21.16), you can specify primer additions such as a Shine-Dalgarno site, start codon etc. Click in the text field and press **Shift + F1** to show some of the most common additions (see figure 21.17).

Use the up and down arrow keys to select a tag and press **Enter**. This will insert the selected sequence as shown in figure 21.18.

At the bottom of the dialog, you can see a preview of what the final PCR product will look like. In the middle there is the sequence of interest (i.e. the sequence you selected as input). In the beginning is the attB1 site, and at the end is the attB2 site. The primer additions that you have inserted are shown in colors (like the green Shine-Dalgarno site in figure 21.18).

Figure 21.15: Selecting which attB sites to add.

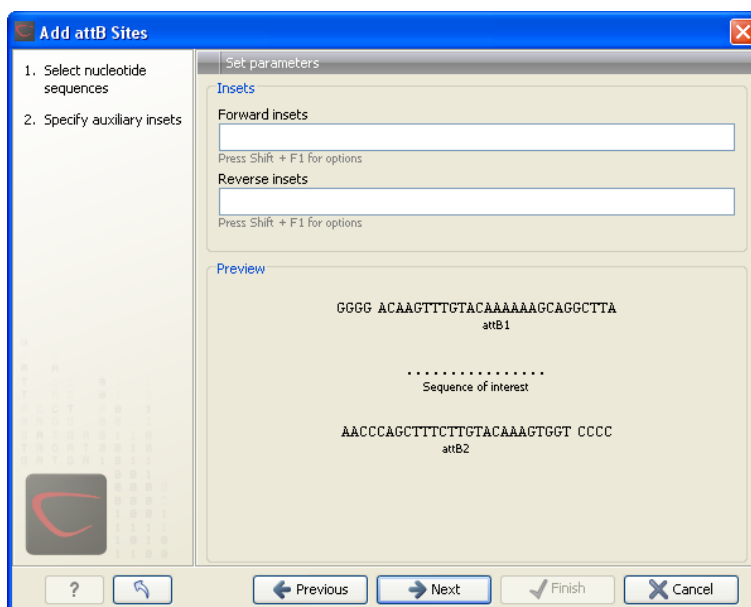

Figure 21.16: Primer additions 5' of the template-specific part of the primer.

This default list of primer additions can be modified, see section [21.2.1](#).

You can also manually type a sequence with the keyboard or paste in a sequence from the clipboard by pressing **Ctrl + v** (**⌘ + v** on Mac).

Clicking **Next** allows you to specify the length of the template-specific part of the primers as shown in figure [21.19](#).

The *CLC Main Workbench* is not doing any kind of primer design when adding the attB sites. As a user, you simply specify the length of the template-specific part of the primer, and together with the attB sites and optional primer additions, this will be the primer. The primer region will be annotated in the resulting attB-flanked sequence and you can also get a list of primers as you can see when clicking **Next** (see figure [21.20](#)).

Figure 21.17: Pressing **Shift + F1** shows some of the common additions. This default list can be modified, see section 21.2.1.

Figure 21.18: A Shine-Dalgarno sequence has been inserted.

Besides the main output which is a copy of the the input sequence(s) now including attB sites and primer additions, you can get a list of primers as output. Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

The attB sites, the primer additions and the primer regions are annotated in the final result as shown in figure 21.21.

There will be one output sequence for each sequence you have selected for adding attB sites. **Save** (📁) the resulting sequence as it will be the input to the next part of the Gateway cloning work flow (see section 21.2.2). When you open the sequence again, you may need to switch on the relevant annotation types to show the sites and primer additions as illustrated in figure 21.21.

Figure 21.19: Specifying the length of the template-specific part of the primers.

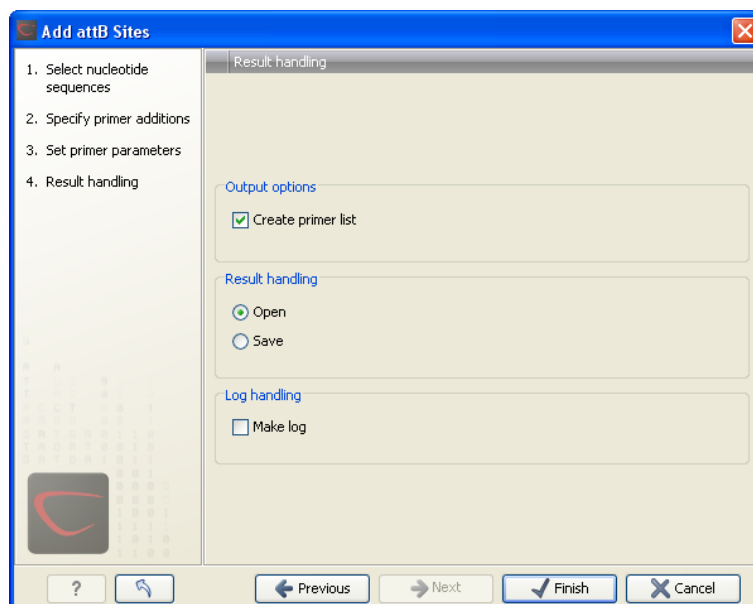

Figure 21.20: Besides the main output which is a copy of the the input sequence(s) now including attB sites and primer additions, you can get a list of primers as output.

Extending the pre-defined list of primer additions

The list of primer additions shown when pressing **Shift+F1** in the dialog shown in figure 21.16 can be configured and extended. If there is a tag that you use a lot, you can add it to the list for convenient and easy access later on. This is done in the **Preferences**:

Edit | Preferences | Advanced

In the advanced preferences dialog, scroll to the part called **Gateway cloning primer additions** (see figure 21.22).

Each element in the list has the following information:

Name The name of the sequence. When the sequence fragment is extended with a primer

Figure 21.21: the attB site plus the Shine-Dalgarno primer addition is annotated.

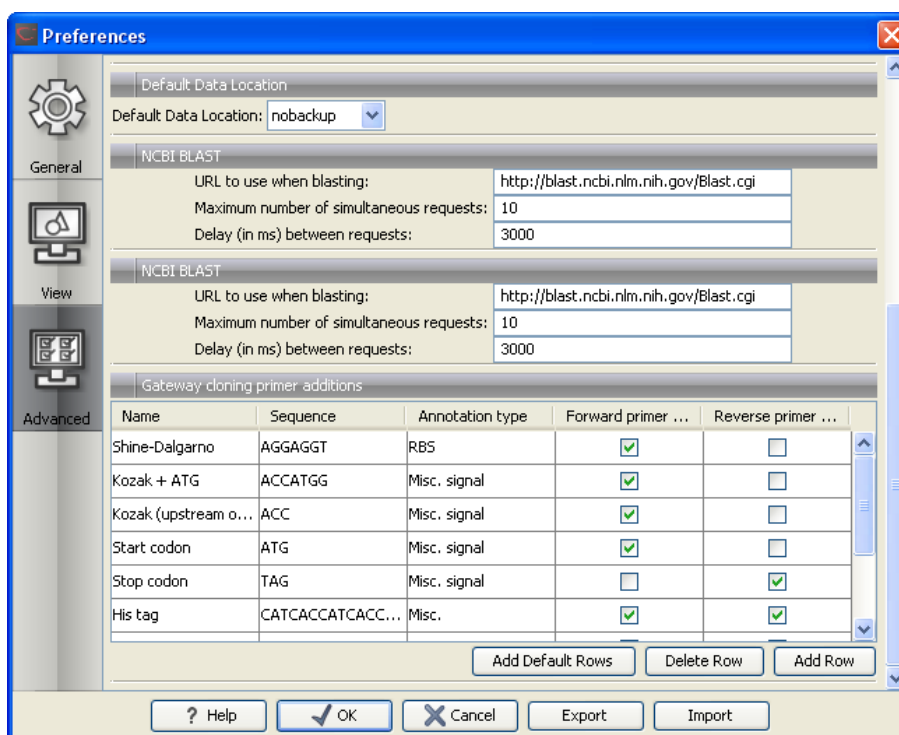

Figure 21.22: Configuring the list of primer additions available when adding attB sites.

addition, an annotation will be added displaying this name.

Sequence The actual sequence to be inserted. The sequence is always defined on the sense strand (although the reverse primer would be reverse complement).

Annotation type The annotation type used for the annotation that is added to the fragment.

Forward primer addition Whether this addition should be visible in the list of additions for the forward primer.

Reverse primer addition Whether this addition should be visible in the list of additions for the reverse primer.

You can either change the existing elements in the table by double-clicking any of the cells, or you can use the buttons below to: **Add Row** or **Delete Row**. If you by accident have deleted or

modified some of the default primer additions, you can press **Add Default Rows**. Note that this will not reset the table but only add all the default rows to the existing rows.

21.2.2 Create entry clones (BP)

The next step in the Gateway cloning work flow is to recombine the attB-flanked sequence of interest into a donor vector to create an entry clone, the so-called BP reaction:

Toolbox in the Menu Bar | Cloning and Restriction Sites (🔗) | Gateway Cloning (📁) | Create Entry Clone (🔄)

This will open a dialog where you can select on or more sequences that will be the sequence of interest to be recombined into your donor vector. Note that the sequences you select should be flanked with attB sites (see section 21.2.1). You can select more than one sequence as input, and the corresponding number of entry clones will be created.

When you have selected your sequence(s), click **Next**.

This will display the dialog shown in figure 21.23.

Figure 21.23: Selecting one or more donor vectors.

Clicking the **Browse** (🔍) button opens a dialog where you can select a donor vector. You can download donor vectors from Invitrogen's web site: <http://tools.invitrogen.com/downloads/Gateway%20vectors.ma4> and import into the *CLC Main Workbench*. Note that the Workbench looks for the specific sequences of the attP sites in the sequences that you select in this dialog (see how to change the definition of sites in appendix G). Note that the *CLC Main Workbench* only checks that valid attP sites are found - it does not check that they correspond to the attB sites of the selected fragments at this step. If the right combination of attB and attP sites is not found, no entry clones will be produced.

Below there is a preview of the fragments selected and the attB sites that they contain. This can be used to get an overview of which entry clones should be used and check that the right attB sites have been added to the fragments.

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

The output is one entry clone per sequence selected. The attB and attP sites have been used for the recombination, and the entry clone is now equipped with attL sites as shown in figure 21.24.

Figure 21.24: The resulting entry vector opened in a circular view.

Note that the bi-product of the recombination is not part of the output.

21.2.3 Create expression clones (LR)

The final step in the Gateway cloning work flow is to recombine the entry clone into a destination vector to create an expression clone, the so-called LR reaction:

Toolbox in the Menu Bar | Cloning and Restriction Sites (🔗) | Gateway Cloning (📁) | Create Expression Clone (🔄)

This will open a dialog where you can select on or more entry clones (see how to create an entry clone in section 21.2.2). If you wish to perform separate LR reactions with multiple entry clones, you should run the **Create Expression Clone** in batch mode (see section 9.1).

When you have selected your entry clone(s), click **Next**.

This will display the dialog shown in figure 21.25.

Clicking the **Browse** (🔍) button opens a dialog where you can select a destination vector. You can download donor vectors from Invitrogen's web site: <http://tools.invitrogen.com/downloads/Gateway%20vectors.ma4> and import into the *CLC Main Workbench*. Note that the Workbench looks for the specific sequences of the attR sites in the sequences that you select in this dialog (see how to change the definition of sites in appendix G). Note that the *CLC Main Workbench* only checks that valid attR sites are found - it does not check that they correspond to the attL sites of the selected fragments at this step. If the right combination of attL and attR sites is not found, no entry clones will be produced.

When performing multi-site gateway cloning, the *CLC Main Workbench* will insert the fragments (contained in entry clones) by matching the sites that are compatible. If the sites have been defined correctly, an expression clone containing all the fragments will be created. You can find an explanation of the multi-site gateway system at <http://tools.invitrogen.com/downloads/gateway-multisite-seminar.html>

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

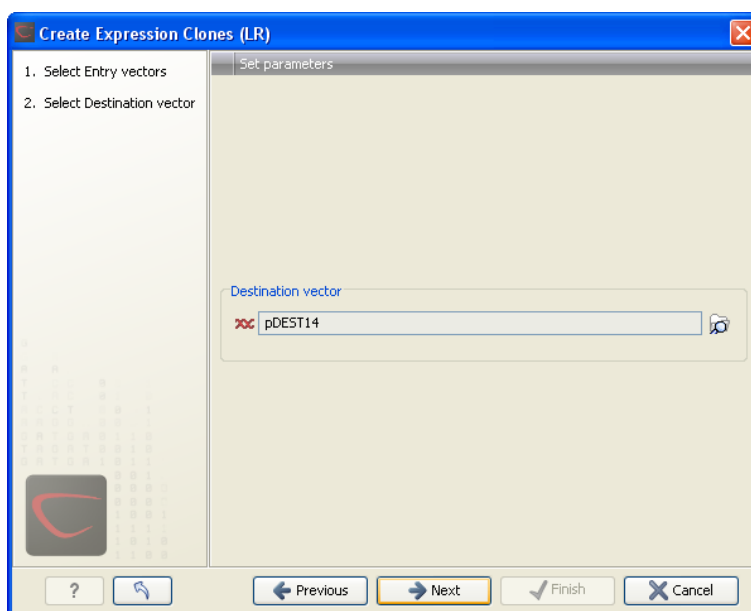

Figure 21.25: Selecting one or more destination vectors.

The output is a number of expression clones depending on how many entry clones and destination vectors that you selected. The attL and attR sites have been used for the recombination, and the expression clone is now equipped with attB sites as shown in figure 21.26.

Figure 21.26: The resulting expression clone opened in a circular view.

You can choose to create a sequence list with the bi-products as well.

21.3 Restriction site analysis

There are two ways of finding and showing restriction sites:

- In many cases, the dynamic restriction sites found in the **Side Panel** of sequence views will be useful, since it is a quick and easy way of showing restriction sites.
- In the **Toolbox** you will find the other way of doing restriction site analyses. This way provides more control of the analysis and gives you more output options, e.g. a table

of restriction sites and you can perform the same restriction map analysis on several sequences in one step.

This chapter first describes the dynamic restriction sites, followed by "the toolbox way". This section also includes an explanation of how to simulate a gel with the selected enzymes. The final section in this chapter focuses on enzyme lists which represent an easy way of managing restriction enzymes.

21.3.1 Dynamic restriction sites

If you open a sequence, a sequence list etc, you will find the **Restriction Sites** group in the **Side Panel**.

As shown in figure 21.27 you can display restriction sites as colored triangles and lines on the sequence. The **Restriction sites** group in the side panel shows a list of enzymes, represented by different colors corresponding to the colors of the triangles on the sequence. By selecting or deselecting the enzymes in the list, you can specify which enzymes' restriction sites should be displayed.

Figure 21.27: Showing restriction sites of ten restriction enzymes.

The color of the restriction enzyme can be changed by clicking the colored box next to the enzyme's name. The name of the enzyme can also be shown next to the restriction site by selecting **Show name flags** above the list of restriction enzymes.

There is also an option to specify how the **Labels** shown be shown:

- **No labels.** This will just display the cut site with no information about the name of the enzyme. Placing the mouse button on the cut site will reveal this information as a tool tip.

- **Flag.** This will place a flag just above the sequence with the enzyme name (see an example in figure 21.28). Note that this option will make it hard to see when several cut sites are located close to each other. In the circular view, this option is replaced by the Radial option:
- **Radial.** This option is only available in the circular view. It will place the restriction site labels as close to the cut site as possible (see an example in figure 21.30).
- **Stacked.** This is similar to the flag option for linear sequence views, but it will stack the labels so that all enzymes are shown. For circular views, it will align all the labels on each side of the circle. This can be useful for clearly seeing the order of the cut sites when they are located closely together (see an example in figure 21.29).

Figure 21.28: Restriction site labels shown as flags.

Figure 21.29: Restriction site labels stacked.

Figure 21.30: Restriction site labels in radial layout.

Note that in a circular view, the **Stacked** and **Radial** options also affect the layout of annotations.

Sort enzymes

Just above the list of enzymes there are three buttons to be used for sorting the list (see figure 21.31):

Figure 21.31: Buttons to sort restriction enzymes.

- **Sort enzymes alphabetically (AA).** Clicking this button will sort the list of enzymes alphabetically.
- **Sort enzymes by number of restriction sites (T#).** This will divide the enzymes into four groups:
 - Non-cutters.

- Single cutters.
- Double cutters.
- Multiple cutters.

There is a checkbox for each group which can be used to hide / show all the enzymes in a group.

-
- **Sort enzymes by overhang** (T, I). This will divide the enzymes into three groups:
 - Blunt. Enzymes cutting both strands at the same position.
 - 3'. Enzymes producing an overhang at the 3' end.
 - 5'. Enzymes producing an overhang at the 5' end.

There is a checkbox for each group which can be used to hide / show all the enzymes in a group.

Manage enzymes

The list of restriction enzymes contains per default 20 of the most popular enzymes, but you can easily modify this list and add more enzymes by clicking the **Manage enzymes button**. This will display the dialog shown in figure 21.32.

Figure 21.32: Adding or removing enzymes from the Side Panel.

At the top, you can choose to **Use existing enzyme list**. Clicking this option lets you select an enzyme list which is stored in the **Navigation Area**. See section 21.5 for more about creating and modifying enzyme lists.

Below there are two panels:

- To the **left**, you see all the enzymes that are in the list select above. If you have not chosen to use an existing enzyme list, this panel shows all the enzymes available ³.

³The CLC Main Workbench comes with a standard set of enzymes based on <http://www.rebase.neb.com>. You can customize the enzyme database for your installation, see section F

- To the **right**, there is a list of the enzymes that will be used.

Select enzymes in the left side panel and add them to the right panel by double-clicking or clicking the **Add** button (➡). If you e.g. wish to use EcoRV and BamHI, select these two enzymes and add them to the right side panel.

If you wish to use all the enzymes in the list:

Click in the panel to the left | press Ctrl + A (⌘ + A on Mac) | Add (➡)

The enzymes can be sorted by clicking the column headings, i.e. Name, Overhang, Methylation or Popularity. This is particularly useful if you wish to use enzymes which produce e.g. a 3' overhang. In this case, you can sort the list by clicking the Overhang column heading, and all the enzymes producing 3' overhangs will be listed together for easy selection.

When looking for a specific enzyme, it is easier to use the Filter. If you wish to find e.g. HindIII sites, simply type HindIII into the filter, and the list of enzymes will shrink automatically to only include the HindIII enzyme. This can also be used to only show enzymes producing e.g. a 3' overhang as shown in figure 21.51.

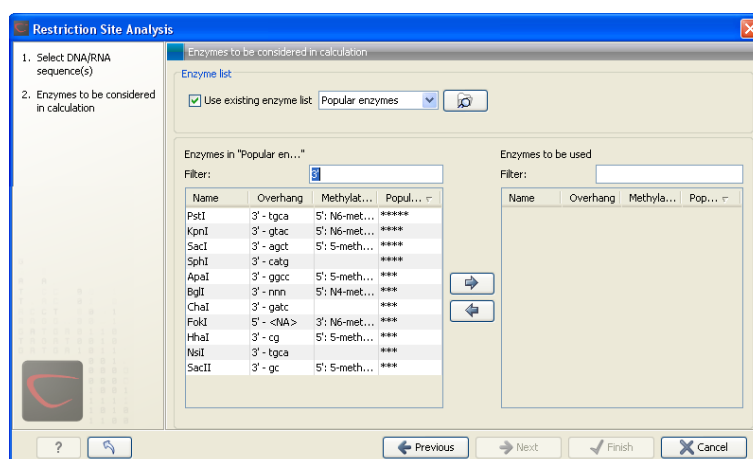

Figure 21.33: Selecting enzymes.

If you need more detailed information and filtering of the enzymes, either place your mouse cursor on an enzyme for one second to display additional information (see figure 21.52), or use the view of enzyme lists (see 21.5).

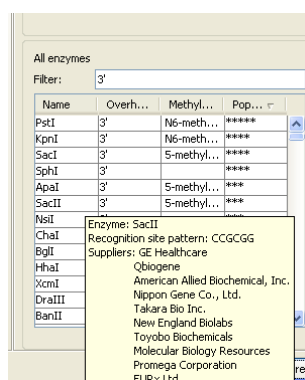

Figure 21.34: Showing additional information about an enzyme like recognition sequence or a list of commercial vendors.

At the bottom of the dialog, you can select to save this list of enzymes as a new file. In this way, you can save the selection of enzymes for later use.

When you click **Finish**, the enzymes are added to the Side Panel and the cut sites are shown on the sequence.

If you have specified a set of enzymes which you always use, it will probably be a good idea to save the settings in the Side Panel (see section 3.1.7) for future use.

Show enzymes cutting inside/outside selection

Section 21.3.1 describes how to add more enzymes to the list in the Side Panel based on the name of the enzyme, overhang, methylation sensitivity etc. However, you will often find yourself in a situation where you need a more sophisticated and explorative approach.

An illustrative example: you have a selection on a sequence, and you wish to find enzymes cutting within the selection, but not outside. This problem often arises during design of cloning experiments. In this case, you do not know the name of the enzyme, so you want the Workbench to find the enzymes for you:

right-click the selection | Show Enzymes Cutting Inside/Outside Selection (🔍)

This will display the dialog shown in figure 21.35 where you can specify which enzymes should initially be considered.

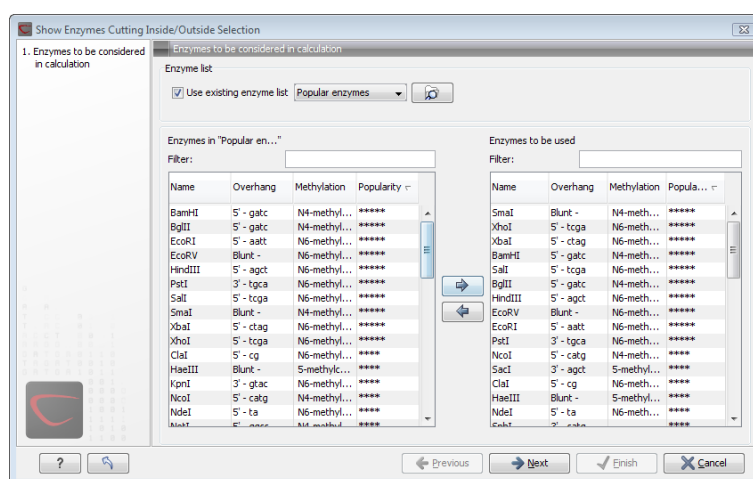

Figure 21.35: Choosing enzymes to be considered.

At the top, you can choose to **Use existing enzyme list**. Clicking this option lets you select an enzyme list which is stored in the **Navigation Area**. See section 21.5 for more about creating and modifying enzyme lists.

Below there are two panels:

- To the **left**, you see all the enzymes that are in the list select above. If you have not chosen to use an existing enzyme list, this panel shows all the enzymes available ⁴.
- To the **right**, there is a list of the enzymes that will be used.

⁴The CLC Main Workbench comes with a standard set of enzymes based on <http://www.rebase.neb.com>. You can customize the enzyme database for your installation, see section F

Select enzymes in the left side panel and add them to the right panel by double-clicking or clicking the **Add** button (➡). If you e.g. wish to use EcoRV and BamHI, select these two enzymes and add them to the right side panel.

If you wish to use all the enzymes in the list:

Click in the panel to the left | press Ctrl + A (⌘ + A on Mac) | Add (➡)

The enzymes can be sorted by clicking the column headings, i.e. Name, Overhang, Methylation or Popularity. This is particularly useful if you wish to use enzymes which produce e.g. a 3' overhang. In this case, you can sort the list by clicking the Overhang column heading, and all the enzymes producing 3' overhangs will be listed together for easy selection.

When looking for a specific enzyme, it is easier to use the Filter. If you wish to find e.g. HindIII sites, simply type HindIII into the filter, and the list of enzymes will shrink automatically to only include the HindIII enzyme. This can also be used to only show enzymes producing e.g. a 3' overhang as shown in figure 21.51.

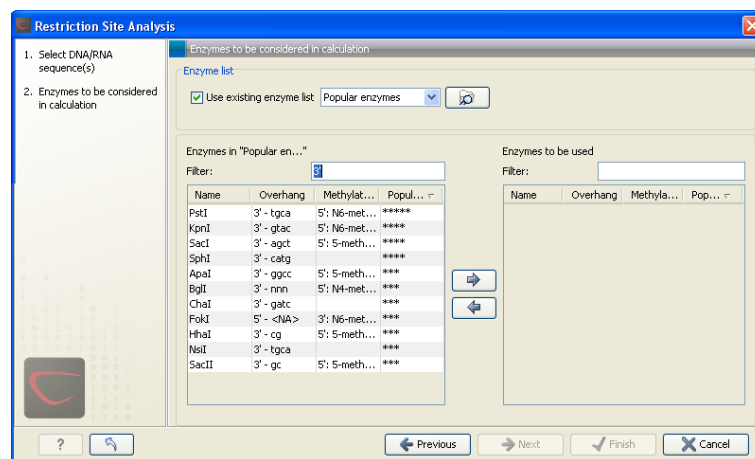

Figure 21.36: Selecting enzymes.

If you need more detailed information and filtering of the enzymes, either place your mouse cursor on an enzyme for one second to display additional information (see figure 21.52), or use the view of enzyme lists (see 21.5).

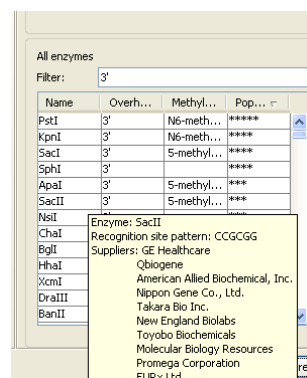

Figure 21.37: Showing additional information about an enzyme like recognition sequence or a list of commercial vendors.

Clicking **Next** will show the dialog in figure 21.38.

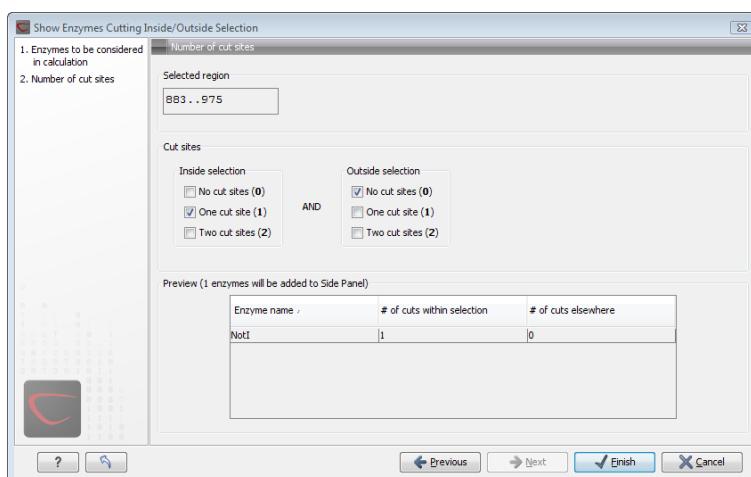

Figure 21.38: Deciding number of cut sites inside and outside the selection.

At the top of the dialog, you see the selected region, and below are two panels:

- **Inside selection.** Specify how many times you wish the enzyme to cut inside the selection. In the example described above, "One cut site (1)" should be selected to only show enzymes cutting once in the selection.
- **Outside selection.** Specify how many times you wish the enzyme to cut outside the selection (i.e. the rest of the sequence). In the example above, "No cut sites (0)" should be selected.

These panels offer a lot of flexibility for combining number of cut sites inside and outside the selection, respectively. To give a hint of how many enzymes will be added based on the combination of cut sites, the preview panel at the bottom lists the enzymes which will be added when you click **Finish**. Note that this list is dynamically updated when you change the number of cut sites. The enzymes shown in brackets [] are enzymes which are already present in the Side Panel.

If you have selected more than one region on the sequence (using Ctrl or ⌘), they will be treated as individual regions. This means that the criteria for cut sites apply to each region.

Show enzymes with compatible ends

Besides what is described above, there is a third way of adding enzymes to the Side Panel and thereby displaying them on the sequence. It is based on the overhang produced by cutting with an enzyme and will find enzymes producing a compatible overhang:

right-click the restriction site | Show Enzymes with Compatible Ends (⌘ I)

This will display the dialog shown in figure 21.39.

At the top you can choose whether the enzymes considered should have an exact match or not. Since a number of restriction enzymes have ambiguous cut patterns, there will be variations in the resulting overhangs. Choosing **All matches**, you cannot be 100% sure that the overhang will match, and you will need to inspect the sequence further afterwards.

Figure 21.39: *Enzymes with compatible ends.*

We advise trying **Exact match** first, and use **All matches** as an alternative if a satisfactory result cannot be achieved.

At the bottom of the dialog, the list of enzymes producing compatible overhangs is shown. Use the arrows to add enzymes which will be displayed on the sequence which you press **Finish**.

When you have added the relevant enzymes, click **Finish**, and the enzymes will be added to the Side Panel and their cut sites displayed on the sequence.

21.3.2 Restriction site analysis from the Toolbox

Besides the dynamic restriction sites, you can do a more elaborate restriction map analysis with more output format using the Toolbox:

Toolbox | Cloning and Restriction Sites (🔗) | Restriction Site Analysis (✂️)

This will display the dialog shown in figure 21.40.

Figure 21.40: *Choosing sequence ATP8a1 mRNA for restriction map analysis.*

If a sequence was selected before choosing the Toolbox action, this sequence is now listed in the **Selected Elements** window of the dialog. Use the arrows to add or remove sequences or

sequence lists from the selected elements.

Selecting, sorting and filtering enzymes

Clicking **Next** lets you define which enzymes to use as basis for finding restriction sites on the sequence. At the top, you can choose to **Use existing enzyme list**. Clicking this option lets you select an enzyme list which is stored in the **Navigation Area**. See section 21.5 for more about creating and modifying enzyme lists.

Below there are two panels:

- To the **left**, you see all the enzymes that are in the list select above. If you have not chosen to use an existing enzyme list, this panel shows all the enzymes available ⁵.
- To the **right**, there is a list of the enzymes that will be used.

Select enzymes in the left side panel and add them to the right panel by double-clicking or clicking the **Add** button (➡). If you e.g. wish to use EcoRV and BamHI, select these two enzymes and add them to the right side panel.

If you wish to use all the enzymes in the list:

Click in the panel to the left | press Ctrl + A (⌘ + A on Mac) | Add (➡)

The enzymes can be sorted by clicking the column headings, i.e. Name, Overhang, Methylation or Popularity. This is particularly useful if you wish to use enzymes which produce e.g. a 3' overhang. In this case, you can sort the list by clicking the Overhang column heading, and all the enzymes producing 3' overhangs will be listed together for easy selection.

When looking for a specific enzyme, it is easier to use the Filter. If you wish to find e.g. HindIII sites, simply type HindIII into the filter, and the list of enzymes will shrink automatically to only include the HindIII enzyme. This can also be used to only show enzymes producing e.g. a 3' overhang as shown in figure 21.51.

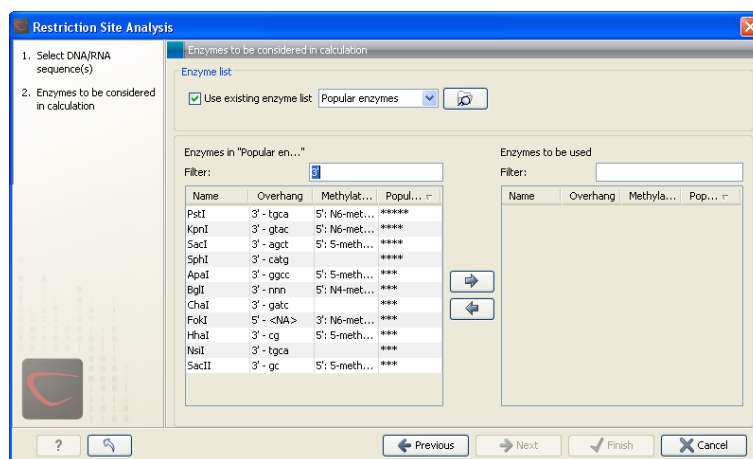

Figure 21.41: Selecting enzymes.

⁵The CLC Main Workbench comes with a standard set of enzymes based on <http://www.rebase.neb.com>. You can customize the enzyme database for your installation, see section F

If you need more detailed information and filtering of the enzymes, either place your mouse cursor on an enzyme for one second to display additional information (see figure 21.52), or use the view of enzyme lists (see 21.5).

Figure 21.42: Showing additional information about an enzyme like recognition sequence or a list of commercial vendors.

Number of cut sites

Clicking **Next** confirms the list of enzymes which will be included in the analysis, and takes you to the dialog shown in figure 21.43.

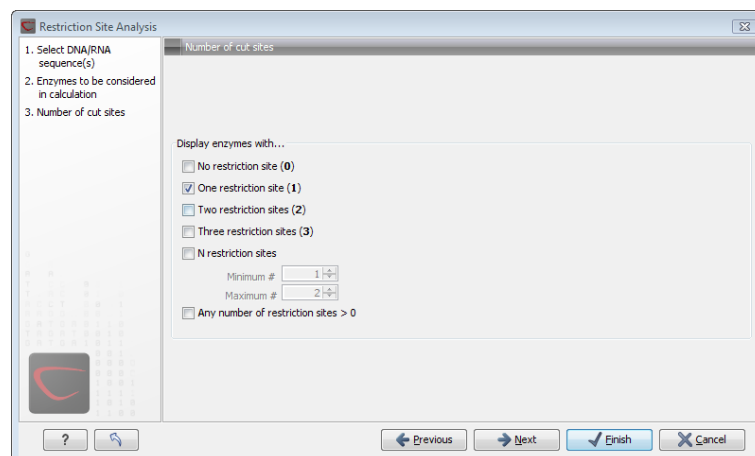

Figure 21.43: Selecting number of cut sites.

If you wish the output of the restriction map analysis only to include restriction enzymes which cut the sequence a specific number of times, use the checkboxes in this dialog:

- No restriction site (**0**)
- One restriction site (**1**)
- Two restriction sites (**2**)
- Three restriction site (**3**)
- N restriction sites
 - Minimum

- Maximum
- Any number of restriction sites > 0

The default setting is to include the enzymes which cut the sequence one or two times.

You can use the checkboxes to perform very specific searches for restriction sites: e.g. if you wish to find enzymes which do not cut the sequence, or enzymes cutting exactly twice.

Output of restriction map analysis

Clicking next shows the dialog in figure 21.44.

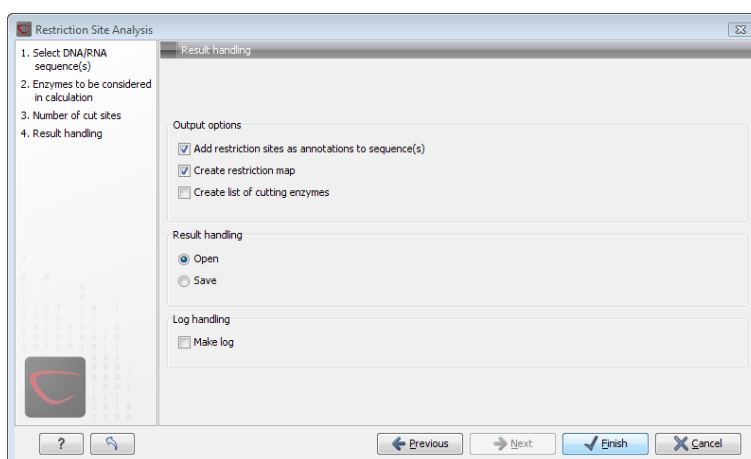

Figure 21.44: Choosing to add restriction sites as annotations or creating a restriction map.

This dialog lets you specify how the result of the restriction map analysis should be presented:

- **Add restriction sites as annotations to sequence(s).** This option makes it possible to see the restriction sites on the sequence (see figure 21.45) and save the annotations for later use.
- **Create restriction map.** When a restriction map is created, it can be shown in three different ways:
 - As a **table of restriction sites** as shown in figure 21.46. If more than one sequence were selected, the table will include the restriction sites of all the sequences. This makes it easy to compare the result of the restriction map analysis for two sequences.
 - As a **table of fragments** which shows the sequence fragments that would be the result of cutting the sequence with the selected enzymes (see figure 21.47).
 - As a **virtual gel** simulation which shows the fragments as bands on a gel (see figure 21.49).
For more information about gel electrophoresis, see section 21.4.

The following sections will describe these output formats in more detail.

In order to complete the analysis click **Finish** (see section 9.2 for information about the Save and Open options).

Restriction sites as annotation on the sequence

If you chose to add the restriction sites as annotation to the sequence, the result will be similar to the sequence shown in figure 21.45. See section 11.3 for more information about viewing

Figure 21.45: The result of the restriction analysis shown as annotations.

annotations.

Table of restriction sites

The restriction map can be shown as a table of restriction sites (see figure 21.46).

Sequ...	Name	Pattern	Overhang	Number ...	Cut position(s)
PERH3BC	CjePI	ccannnnnntc	3'	1	(151, 184)
PERH3BC	MboII	gaaga	3'	1	86
PERH3BC	NcuI	gaaga	3'	1	86
PERH3BC	TsoI	tarcca	3'	1	[134]
PERH3BC	Tth111II	caarca	3'	1	[101]

Figure 21.46: The result of the restriction analysis shown as annotations.

Each row in the table represents a restriction enzyme. The following information is available for each enzyme:

- **Sequence.** The name of the sequence which is relevant if you have performed restriction map analysis on more than one sequence.
- **Name.** The name of the enzyme.
- **Pattern.** The recognition sequence of the enzyme.
- **Overhang.** The overhang produced by cutting with the enzyme (3', 5' or Blunt).
- **Number of cut sites.**
- **Cut position(s).** The position of each cut.
 - , If the enzyme cuts more than once, the positions are separated by commas.
 - [] If the enzyme's recognition sequence is on the negative strand, the cut position is put in brackets (as the enzyme TsoI in figure 21.46 whose cut position is [134]).
 - () Some enzymes cut the sequence twice for each recognition site, and in this case the two cut positions are surrounded by parentheses.

Table of restriction fragments

The restriction map can be shown as a table of fragments produced by cutting the sequence with the enzymes:

Click the **Fragments** button () at the bottom of the view

The table is shown in see figure 21.47.

Sequence	Length	Region	Overhangs	Left end	Right end	Conflicting enzymes
PERH3BC	35	100..134TG AC.....	Tth111II	TsoI	TsoI, CjePI
PERH3BC	52	100..151GTTATT AC.....	Tth111II	CjePI	TsoI, CjePI
PERH3BC	19	133..151GTTATT AC.....	TsoI	CjePI	TsoI, CjePI
PERH3BC	39	146..184CTCTCA CAATAA.....	CjePI	CjePI	
PERH3BC	18	179..196GAGACT.....	CjePI		

Figure 21.47: The result of the restriction analysis shown as annotations.

Each row in the table represents a fragment. If more than one enzyme cuts in the same region, or if an enzyme's recognition site is cut by another enzyme, there will be a fragment for each of the possible cut combinations ⁶. The following information is available for each fragment.

- **Sequence.** The name of the sequence which is relevant if you have performed restriction map analysis on more than one sequence.
- **Length.** The length of the fragment. If there are overhangs of the fragment, these are included in the length (both 3' and 5' overhangs).
- **Region.** The fragment's region on the original sequence.
- **Overhangs.** If there is an overhang, this is displayed with an abbreviated version of the fragment and its overhangs. The two rows of dots (.) represent the two strands of the fragment and the overhang is visualized on each side of the dots with the residue(s) that make up the overhang. If there are only the two rows of dots, it means that there is no overhang.
- **Left end.** The enzyme that cuts the fragment to the left (5' end).
- **Right end.** The enzyme that cuts the fragment to the right (3' end).

⁶Furthermore, if this is the case, you will see the names of the other enzymes in the **Conflicting Enzymes** column

- **Conflicting enzymes.** If more than one enzyme cuts at the same position, or if an enzyme's recognition site is cut by another enzyme, a fragment is displayed for each possible combination of cuts. At the same time, this column will display the enzymes that are in conflict. If there are conflicting enzymes, they will be colored red to alert the user. If the same experiment were performed in the lab, conflicting enzymes could lead to wrong results. For this reason, this functionality is useful to simulate digestions with complex combinations of restriction enzymes.

If views of both the fragment table and the sequence are open, clicking in the fragment table will select the corresponding region on the sequence.

Gel

The restriction map can also be shown as a gel. This is described in section [21.4.1](#).

21.4 Gel electrophoresis

CLC Main Workbench enables the user to simulate the separation of nucleotide sequences on a gel. This feature is useful when e.g. designing an experiment which will allow the differentiation of a successful and an unsuccessful cloning experiment on the basis of a restriction map.

There are two main ways to simulate gel separation of nucleotide sequences:

- One or more sequences can be digested with restriction enzymes and the resulting fragments can be separated on a gel.
- A number of existing sequences can be separated on a gel.

There are several ways to apply these functionalities as described below.

21.4.1 Separate fragments of sequences on gel

This section explains how to simulate a gel electrophoresis of one or more sequences which are digested with restriction enzymes. There are two ways to do this:

- When performing the **Restriction Site Analysis** from the **Toolbox**, you can choose to create a restriction map which can be shown as a gel. This is explained in section [??](#).
- From all the graphical views of sequences, you can right-click the name of the sequence and choose: **Digest Sequence with Selected Enzymes and Run on Gel** (). The views where this option is available are listed below:
 - Circular view (see section [11.2](#)).
 - Ordinary sequence view (see section [11.1](#)).
 - Graphical view of sequence lists (see section [11.7](#)).
 - Cloning editor (see section [21.1](#)).
 - Primer designer (see section [18.3](#)).

Furthermore, you can also right-click an empty part of the view of the graphical view of sequence lists and the cloning editor and choose **Digest All Sequences with Selected Enzymes and Run on Gel**.

Note! When using the right-click options, the sequence will be digested with the enzymes that are selected in the **Side Panel**. This is explained in section 11.1.2.

The view of the gel is explained in section 21.4.3

21.4.2 Separate sequences on gel

To separate sequences without restriction enzyme digestion, first create a sequence list of the sequences in question (see section 11.7). Then click the **Gel** button () at the bottom of the view of the sequence list.

Figure 21.48: A sequence list shown as a gel.

For more information about the view of the gel, see the next section.

21.4.3 Gel view

In figure 21.49 you can see a simulation of a gel with its **Side Panel** to the right. This view will be explained in this section.

Information on bands / fragments

You can get information about the individual bands by hovering the mouse cursor on the band of interest. This will display a tool tip with the following information:

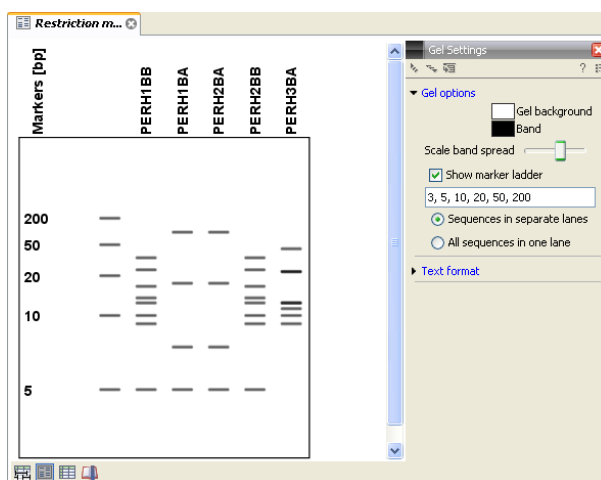

Figure 21.49: Five lanes showing fragments of five sequences cut with restriction enzymes.

- Fragment length
- Fragment region on the original sequence
- Enzymes cutting at the left and right ends, respectively

For gels comparing whole sequences, you will see the sequence name and the length of the sequence.

Note! You have to be in **Selection** () or **Pan** () mode in order to get this information.

It can be useful to add markers to the gel which enables you to compare the sizes of the bands. This is done by clicking **Show marker ladder** in the **Side Panel**.

Markers can be entered into the text field, separated by commas.

Modifying the layout

The background of the lane and the colors of the bands can be changed in the **Side Panel**. Click the colored box to display a dialog for picking a color. The slider **Scale band spread** can be used to adjust the effective time of separation on the gel, i.e. how much the bands will be spread over the lane. In a real electrophoresis experiment this property will be determined by several factors including time of separation, voltage and gel density.

You can also choose how many lanes should be displayed:

- **Sequences in separate lanes.** This simulates that a gel is run for each sequence.
- **All sequences in one lane.** This simulates that one gel is run for all sequences.

You can also modify the layout of the view by zooming in or out. Click **Zoom in** () or **Zoom out** () in the Toolbar and click the view.

Finally, you can modify the format of the text heading each lane in the **Text format** preferences in the **Side Panel**.

21.5 Restriction enzyme lists

CLC Main Workbench includes all the restriction enzymes available in the **REBASE** database⁷. However, when performing restriction site analyses, it is often an advantage to use a customized list of enzymes. In this case, the user can create special lists containing e.g. all enzymes available in the laboratory freezer, all enzymes used to create a given restriction map or all enzymes that are available from the preferred vendor.

In the example data (see section 1.6.2) under Nucleotide->Restriction analysis, there are two enzyme lists: one with the 50 most popular enzymes, and another with all enzymes that are included in the *CLC Main Workbench*.

This section describes how you can create an enzyme list, and how you can modify it.

21.5.1 Create enzyme list

CLC Main Workbench uses enzymes from the **REBASE** restriction enzyme database at <http://rebase.neb.com>⁸.

To create an enzyme list of a subset of these enzymes:

File | New | Enzyme list 

This opens the dialog shown in figure 21.50

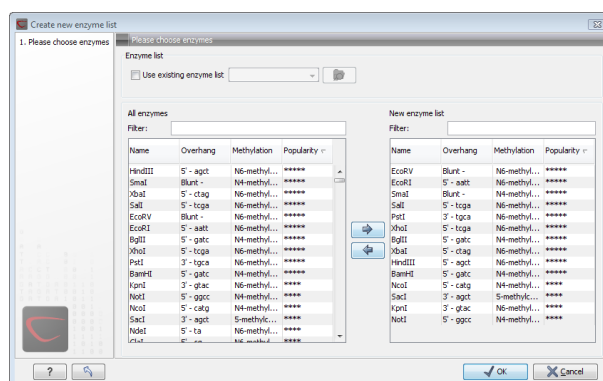

Figure 21.50: Choosing enzymes for the new enzyme list.

At the top, you can choose to **Use existing enzyme list**. Clicking this option lets you select an enzyme list which is stored in the **Navigation Area**. See section 21.5 for more about creating and modifying enzyme lists.

Below there are two panels:

- To the **left**, you see all the enzymes that are in the list select above. If you have not chosen to use an existing enzyme list, this panel shows all the enzymes available⁹.
- To the **right**, there is a list of the enzymes that will be used.

⁷You can customize the enzyme database for your installation, see section F

⁸You can customize the enzyme database for your installation, see section F

⁹The *CLC Main Workbench* comes with a standard set of enzymes based on <http://www.rebase.neb.com>. You can customize the enzyme database for your installation, see section F

Select enzymes in the left side panel and add them to the right panel by double-clicking or clicking the **Add** button (➡). If you e.g. wish to use EcoRV and BamHI, select these two enzymes and add them to the right side panel.

If you wish to use all the enzymes in the list:

Click in the panel to the left | press Ctrl + A (⌘ + A on Mac) | Add (➡)

The enzymes can be sorted by clicking the column headings, i.e. Name, Overhang, Methylation or Popularity. This is particularly useful if you wish to use enzymes which produce e.g. a 3' overhang. In this case, you can sort the list by clicking the Overhang column heading, and all the enzymes producing 3' overhangs will be listed together for easy selection.

When looking for a specific enzyme, it is easier to use the Filter. If you wish to find e.g. HindIII sites, simply type HindIII into the filter, and the list of enzymes will shrink automatically to only include the HindIII enzyme. This can also be used to only show enzymes producing e.g. a 3' overhang as shown in figure 21.51.

Figure 21.51: *Selecting enzymes.*

If you need more detailed information and filtering of the enzymes, either place your mouse cursor on an enzyme for one second to display additional information (see figure 21.52), or use the view of enzyme lists (see 21.5).

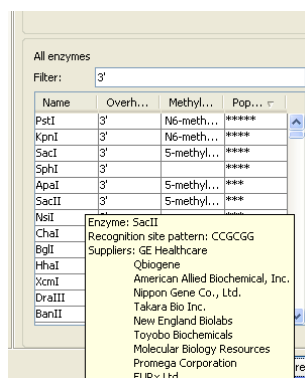

Figure 21.52: *Showing additional information about an enzyme like recognition sequence or a list of commercial vendors.*

Click **Finish** to open the enzyme list.

21.5.2 View and modify enzyme list

An enzyme list is shown in figure 21.53.

The list can be sorted by clicking the columns,

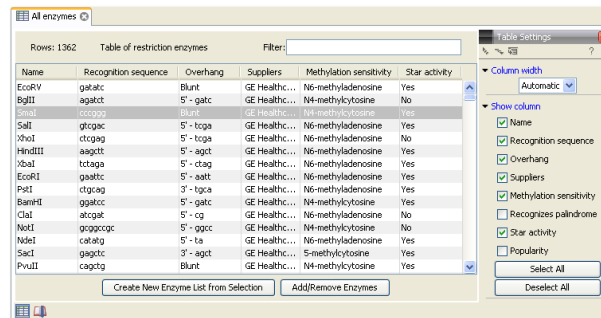

Figure 21.53: An enzyme list.

and you can use the filter at the top right corner to search for specific enzymes, recognition sequences etc.

If you wish to remove or add enzymes, click the **Add/Remove Enzymes** button at the bottom of the view. This will present the same dialog as shown in figure 21.50 with the enzyme list shown to the right.

If you wish to extract a subset of an enzyme list:

open the list | select the relevant enzymes | right-click | Create New Enzyme List from Selection 

If you combined this method with the filter located at the top of the view, you can extract a very specific set of enzymes. E.g. if you wish to create a list of enzymes sold by a particular distributor, type the name of the distributor into the filter, and select and create a new enzyme list from the selection.

CLC Main Workbench can align nucleotides and proteins using a *progressive alignment* algorithm (see section 22.6 or read the White paper on alignments in the **Science** section of <http://www.clcbio.com>).

This chapter describes how to use the program to align sequences. The chapter also describes alignment algorithms in more general terms.

22.1 Create an alignment

Alignments can be created from sequences, sequence lists (see section 11.7), existing alignments and from any combination of the three.

To create an alignment in *CLC Main Workbench*:

select sequences to align | Toolbox in the Menu Bar | Alignments and Trees (📁)| Create Alignment (🔧)

or **select sequences to align | right-click any selected sequence | Toolbox | Alignments and Trees (📁)| Create Alignment (🔧)**

This opens the dialog shown in figure 22.1.

Figure 22.1: Creating an alignment.

If you have selected some elements before choosing the Toolbox action, they are now listed in the **Selected Elements** window of the dialog. Use the arrows to add or remove sequences, sequence lists or alignments from the selected elements. Click **Next** to adjust alignment algorithm parameters. Clicking **Next** opens the dialog shown in figure 22.2.

Figure 22.2: Adjusting alignment algorithm parameters.

22.1.1 Gap costs

The alignment algorithm has three parameters concerning gap costs: Gap open cost, Gap extension cost and End gap cost. The precision of these parameters is to one place of decimal.

- **Gap open cost.** The price for introducing gaps in an alignment.
- **Gap extension cost.** The price for every extension past the initial gap.

If you expect a lot of small gaps in your alignment, the Gap open cost should equal the Gap extension cost. On the other hand, if you expect few but large gaps, the Gap open cost should be set significantly higher than the Gap extension cost.

However, for most alignments it is a good idea to make the Gap open cost quite a bit higher than the Gap extension cost. The default values are 10.0 and 1.0 for the two parameters, respectively.

- **End gap cost.** The price of gaps at the beginning or the end of the alignment. One of the advantages of the *CLC Main Workbench* alignment method is that it provides flexibility in the treatment of gaps at the ends of the sequences. There are three possibilities:
 - **Free end gaps.** Any number of gaps can be inserted in the ends of the sequences without any cost.
 - **Cheap end gaps.** All end gaps are treated as gap extensions and any gaps past 10 are free.
 - **End gaps as any other.** Gaps at the ends of sequences are treated like gaps in any other place in the sequences.

When aligning a long sequence with a short partial sequence, it is ideal to use free end gaps, since this will be the best approximation to the situation. The many gaps inserted at the ends are not due to evolutionary events, but rather to partial data.

Many homologous proteins have quite different ends, often with large insertions or deletions. This confuses alignment algorithms, but using the **Cheap end gaps** option, large gaps will generally be tolerated at the sequence ends, improving the overall alignment. This is the default setting of the algorithm.

Finally, treating end gaps like any other gaps is the best option when you know that there are no biologically distinct effects at the ends of the sequences.

Figures 22.3 and 22.4 illustrate the differences between the different gap scores at the sequence ends.

22.1.2 Fast or accurate alignment algorithm

CLC Main Workbench has two algorithms for calculating alignments:

- **Fast (less accurate).** This allows for use of an optimized alignment algorithm which is very fast. The fast option is particularly useful for data sets with very long sequences.
- **Slow (very accurate).** This is the recommended choice unless you find the processing time too long.

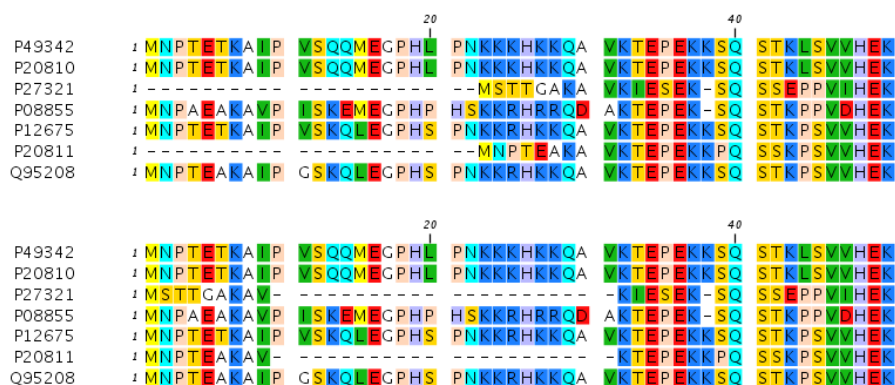

Figure 22.3: The first 50 positions of two different alignments of seven calpastatin sequences. The top alignment is made with cheap end gaps, while the bottom alignment is made with end gaps having the same price as any other gaps. In this case it seems that the latter scoring scheme gives the best result.

Figure 22.4: The alignment of the coding sequence of bovine myoglobin with the full mRNA of human gamma globin. The top alignment is made with free end gaps, while the bottom alignment is made with end gaps treated as any other. The yellow annotation is the coding sequence in both sequences. It is evident that free end gaps are ideal in this situation as the start codons are aligned correctly in the top alignment. Treating end gaps as any other gaps in the case of aligning distant homologs where one sequence is partial leads to a spreading out of the short sequence as in the bottom alignment.

Both algorithms use progressive alignment. The faster algorithm builds the initial tree by doing more approximate pairwise alignments than the slower option.

22.1.3 Aligning alignments

If you have selected an existing alignment in the first step (22.1), you have to decide how this alignment should be treated.

- **Redo alignment.** The original alignment will be realigned if this checkbox is checked. Otherwise, the original alignment is kept in its original form except for possible extra equally sized gaps in all sequences of the original alignment. This is visualized in figure 22.5.

Figure 22.5: The top figures shows the original alignment. In the bottom panel a single sequence with four inserted X's are aligned to the original alignment. This introduces gaps in all sequences of the original alignment. All other positions in the original alignment are fixed.

This feature is useful if you wish to add extra sequences to an existing alignment, in which case you just select the alignment and the extra sequences and choose not to redo the alignment.

It is also useful if you have created an alignment where the gaps are not placed correctly. In this case, you can realign the alignment with different gap cost parameters.

22.1.4 Fixpoints

With fixpoints, you can get full control over the alignment algorithm. The fixpoints are points on the sequences that are forced to align to each other.

Fixpoints are added to sequences or alignments before clicking "Create alignment". To add a fixpoint, open the sequence or alignment and:

Select the region you want to use as a fixpoint | right-click the selection | Set alignment fixpoint here

This will add an annotation labeled "Fixpoint" to the sequence (see figure 22.6). Use this procedure to add fixpoints to the other sequence(s) that should be forced to align to each other.

When you click "Create alignment" and go to **Step 2**, check **Use fixpoints** in order to force the alignment algorithm to align the fixpoints in the selected sequences to each other.

In figure 22.7 the result of an alignment using fixpoints is illustrated.

You can add multiple fixpoints, e.g. adding two fixpoints to the sequences that are aligned will force their first fixpoints to be aligned to each other, and their second fixpoints will also be

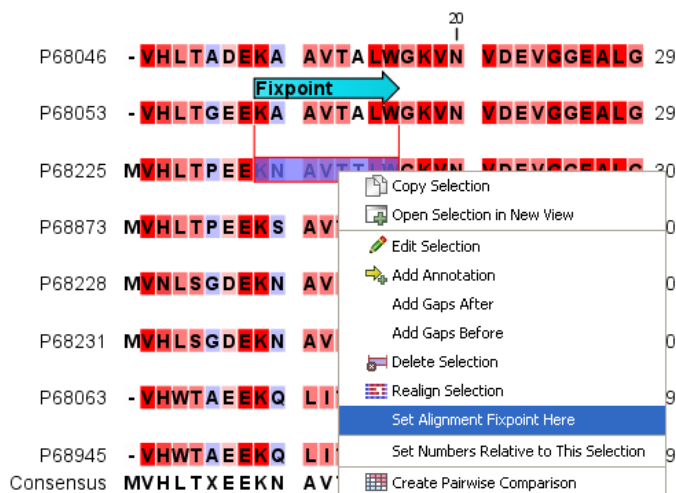

Figure 22.6: Adding a fixpoint to a sequence in an existing alignment. At the top you can see a fixpoint that has already been added.

Figure 22.7: Realigning using fixpoints. In the top view, fixpoints have been added to two of the sequences. In the view below, the alignment has been realigned using the fixpoints. The three top sequences are very similar, and therefore they follow the one sequence (number two from the top) that has a fixpoint.

aligned to each other.

Advanced use of fixpoints

Fixpoints with the same names will be aligned to each other, which gives the opportunity for great control over the alignment process. It is only necessary to change any fixpoint names in very special cases.

One example would be three sequences A, B and C where sequences A and B has one copy of a domain while sequence C has two copies of the domain. You can now force sequence A to align to the first copy and sequence B to align to the second copy of the domains in sequence C. This is done by inserting fixpoints in sequence C for each domain, and naming them 'fp1' and 'fp2'

(for example). Now, you can insert a fixpoint in each of sequences A and B, naming them 'fp1' and 'fp2', respectively. Now, when aligning the three sequences using fixpoints, sequence A will align to the first copy of the domain in sequence C, while sequence B would align to the second copy of the domain in sequence C.

You can name fixpoints by:

right-click the Fixpoint annotation | Edit Annotation (👉) | type the name in the 'Name' field

22.2 View alignments

Since an alignment is a display of several sequences arranged in rows, the basic options for viewing alignments are the same as for viewing sequences. Therefore we refer to section [11.1](#) for an explanation of these basic options.

However, there are a number of alignment-specific view options in the **Alignment info** and the **Nucleotide info** in the **Side Panel** to the right of the view. Below is more information on these view options.

Under **Translation** in the **Nucleotide info**, there is an extra checkbox: **Relative to top sequence**. Checking this box will make the reading frames for the translation align with the top sequence so that you can compare the effect of nucleotide differences on the protein level.

The options in the **Alignment info** relate to each column in the alignment:

- **Consensus.** Shows a consensus sequence at the bottom of the alignment. The consensus sequence is based on every single position in the alignment and reflects an artificial sequence which resembles the sequence information of the alignment, but only as one single sequence. If all sequences of the alignment is 100% identical the consensus sequence will be identical to all sequences found in the alignment. If the sequences of the alignment differ the consensus sequence will reflect the most common sequences in the alignment. Parameters for adjusting the consensus sequences are described below.
 - **Limit.** This option determines how conserved the sequences must be in order to agree on a consensus. Here you can also choose **IUPAC** which will display the ambiguity code when there are differences between the sequences. E.g. an alignment with **A** and a **G** at the same position will display an **R** in the consensus line if the **IUPAC** option is selected. (The IUPAC codes can be found in section [I](#) and [H](#).)
 - **No gaps.** Checking this option will not show gaps in the consensus.
 - **Ambiguous symbol.** Select how ambiguities should be displayed in the consensus line (as **N**, **?**, *****, **.** or **-**). This option has now effect if **IUPAC** is selected in the **Limit** list above.

The **Consensus Sequence** can be opened in a new view, simply by right-clicking the **Consensus Sequence** and click **Open Consensus in New View**.

- **Conservation.** Displays the level of conservation at each position in the alignment. The conservation shows the conservation of all sequence positions. The height of the bar, or the gradient of the color reflect how conserved that particular position is in the alignment. If one position is 100% conserved the bar will be shown in full height, and it is colored in the color specified at the right side of the gradient slider.

- **Foreground color.** Colors the letters using a gradient, where the right side color is used for highly conserved positions and the left side color is used for positions that are less conserved.
- **Background color.** Sets a background color of the residues using a gradient in the same way as described above.
- **Graph.** Displays the conservation level as a graph at the bottom of the alignment. The bar (default view) show the conservation of all sequence positions. The height of the graph reflects how conserved that particular position is in the alignment. If one position is 100% conserved the graph will be shown in full height. Learn how to export the data behind the graph in section 7.4.
 - * **Height.** Specifies the height of the graph.
 - * **Type.** The type of the graph.
 - **Line plot.** Displays the graph as a line plot.
 - **Bar plot.** Displays the graph as a bar plot.
 - **Colors.** Displays the graph as a color bar using a gradient like the foreground and background colors.
 - * **Color box.** Specifies the color of the graph for line and bar plots, and specifies a gradient for colors.
- **Gap fraction.** Which fraction of the sequences in the alignment that have gaps. The gap fraction is only relevant if there are gaps in the alignment.
 - **Foreground color.** Colors the letter using a gradient, where the left side color is used if there are relatively few gaps, and the right side color is used if there are relatively many gaps.
 - **Background color.** Sets a background color of the residues using a gradient in the same way as described above.
 - **Graph.** Displays the gap fraction as a graph at the bottom of the alignment (Learn how to export the data behind the graph in section 7.4).
 - * **Height.** Specifies the height of the graph.
 - * **Type.** The type of the graph.
 - **Line plot.** Displays the graph as a line plot.
 - **Bar plot.** Displays the graph as a line plot.
 - **Colors.** Displays the graph as a color bar using a gradient like the foreground and background colors.
 - * **Color box.** Specifies the color of the graph for line and bar plots, and specifies a gradient for colors.
- **Color different residues.** Indicates differences in aligned residues.
 - **Foreground color.** Colors the letter.
 - **Background color.** Sets a background color of the residues.
- **Sequence logo.** A sequence logo displays the frequencies of residues at each position in an alignment. This is presented as the relative heights of letters, along with the degree of sequence conservation as the total height of a stack of letters, measured in bits of information. The vertical scale is in bits, with a maximum of 2 bits for nucleotides and approximately 4.32 bits for amino acid residues. See section 22.2.1 for more details.

- **Foreground color.** Color the residues using a gradient according to the information content of the alignment column. Low values indicate columns with high variability whereas high values indicate columns with similar residues.
- **Background color.** Sets a background color of the residues using a gradient in the same way as described above.
- **Logo.** Displays sequence logo at the bottom of the alignment.
 - * **Height.** Specifies the height of the sequence logo graph.
 - * **Color.** The sequence logo can be displayed in black or Rasmol colors. For protein alignments, a polarity color scheme is also available, where hydrophobic residues are shown in black color, hydrophilic residues as green, acidic residues as red and basic residues as blue.

22.2.1 Bioinformatics explained: Sequence logo

In the search for homologous sequences, researchers are often interested in conserved sites/residues or positions in a sequence which tend to differ a lot. Most researchers use alignments (see Bioinformatics explained: *multiple alignments*) for visualization of homology on a given set of either DNA or protein sequences. In proteins, active sites in a given protein family are often highly conserved. Thus, in an alignment these positions (which are not necessarily located in proximity) are fully or nearly fully conserved. On the other hand, antigen binding sites in the F_{ab} unit of immunoglobulins tend to differ quite a lot, whereas the rest of the protein remains relatively unchanged.

In DNA, promoter sites or other DNA binding sites are highly conserved (see figure 22.8). This is also the case for repressor sites as seen for the Cro repressor of bacteriophage λ .

When aligning such sequences, regardless of whether they are highly variable or highly conserved at specific sites, it is very difficult to generate a consensus sequence which covers the actual variability of a given position. In order to better understand the information content or significance of certain positions, a sequence logo can be used. The sequence logo displays the information content of all positions in an alignment as residues or nucleotides stacked on top of each other (see figure 22.8). The sequence logo provides a far more detailed view of the entire alignment than a simple consensus sequence. Sequence logos can aid to identify protein binding sites on DNA sequences and can also aid to identify conserved residues in aligned domains of protein sequences and a wide range of other applications.

Each position of the alignment and consequently the sequence logo shows the sequence information in a computed score based on Shannon entropy [Schneider and Stephens, 1990]. The height of the individual letters represent the sequence information content in that particular position of the alignment.

A sequence logo is a much better visualization tool than a simple consensus sequence. An example hereof is an alignment where in one position a particular residue is found in 70% of the sequences. If a consensus sequence is used, it typically only displays the single residue with 70% coverage. In figure 22.8 an un-gapped alignment of 11 *E. coli* start codons including flanking regions are shown. In this example, a consensus sequence would only display ATG as the start codon in position 1, but when looking at the sequence logo it is seen that a GTG is also allowed as a start codon.

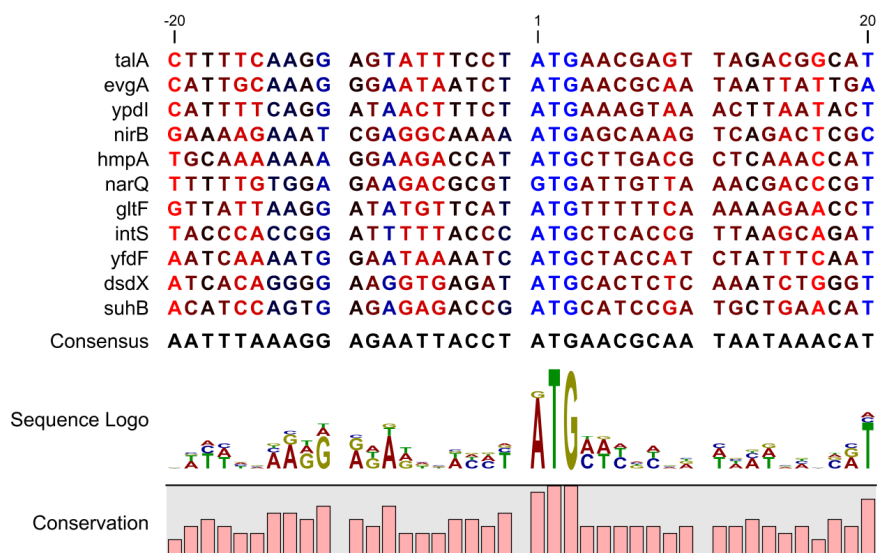

Figure 22.8: Ungapped sequence alignment of eleven *E. coli* sequences defining a start codon. The start codons start at position 1. Below the alignment is shown the corresponding sequence logo. As seen, a GTG start codon and the usual ATG start codons are present in the alignment. This can also be visualized in the logo at position 1.

Calculation of sequence logos

A comprehensive walk-through of the calculation of the information content in sequence logos is beyond the scope of this document but can be found in the original paper by [Schneider and Stephens, 1990]. Nevertheless, the conservation of every position is defined as R_{seq} which is the difference between the maximal entropy (S_{max}) and the observed entropy for the residue distribution (S_{obs}),

$$R_{seq} = S_{max} - S_{obs} = \log_2 N - \left(- \sum_{n=1}^N p_n \log_2 p_n \right)$$

p_n is the observed frequency of a amino acid residue or nucleotide of symbol n at a particular position and N is the number of distinct symbols for the sequence alphabet, either 20 for proteins or four for DNA/RNA. This means that the maximal sequence information content per position is $\log_2 4 = 2 \text{ bits}$ for DNA/RNA and $\log_2 20 \approx 4.32 \text{ bits}$ for proteins.

The original implementation by Schneider does not handle sequence gaps.

We have slightly modified the algorithm so an estimated logo is presented in areas with sequence gaps.

If amino acid residues or nucleotides of one sequence are found in an area containing gaps, we have chosen to show the particular residue as the fraction of the sequences. Example; if one position in the alignment contain 9 gaps and only one alanine (A) the A represented in the logo has a height of 0.1.

22.3 Edit alignments

22.3.1 Move residues and gaps

The placement of gaps in the alignment can be changed by modifying the parameters when creating the alignment (see section 22.1). However, gaps and residues can also be moved after the alignment is created:

select one or more gaps or residues in the alignment | drag the selection to move

This can be done both for single sequences, but also for multiple sequences by making a selection covering more than one sequence. When you have made the selection, the mouse pointer turns into a horizontal arrow indicating that the selection can be moved (see figure 22.9).

Note! Residues can only be moved when they are next to a gap.

```

AGG GAGTCAT      AGG GAGTCAT
AGG GAGTCAT      AGG GAGTCAT
AGG GAGCAGT      AGG GAGCAGT
- - - - -        - - - - -
AGG GTACAGT      AGG GTACAGT
- - - GAGTAGC    - GA G - - TAGC
- - - GAGTAGC    - GA G - - TAGC
- - - GAGTAGC    - GA G - - TAGG
ATG GTGCACC      ATG GTGCACC
ATG GTGCATC      ATG GTGCATC
  
```

Figure 22.9: *Moving a part of an alignment. Notice the change of mouse pointer to a horizontal arrow.*

22.3.2 Insert gaps

The placement of gaps in the alignment can be changed by modifying the parameters when creating the alignment. However, gaps can also be added manually after the alignment is created.

To insert extra gaps:

select a part of the alignment | right-click the selection | Add gaps before/after

If you have made a selection covering e.g. five residues, a gap of five will be inserted. In this way you can easily control the number of gaps to insert. Gaps will be inserted in the sequences that you selected. If you make a selection in two sequences in an alignment, gaps will be inserted into these two sequences. This means that these two sequences will be displaced compared to the other sequences in the alignment.

22.3.3 Delete residues and gaps

Residues or gaps can be deleted for individual sequences or for the whole alignment. For individual sequences:

select the part of the sequence you want to delete | right-click the selection | Edit Selection () | Delete the text in the dialog | Replace

The selection shown in the dialog will be replaced by the text you enter. If you delete the text, the selection will be replaced by an empty text, i.e. deleted.

To delete entire columns:

select the part of the alignment you want to delete | right-click the selection | Delete columns

The selection may cover one or more sequences, but the **Delete columns** function will always apply to the entire alignment.

22.3.4 Copy annotations to other sequences

Annotations on one sequence can be transferred to other sequences in the alignment:

right-click the annotation | Copy Annotation to other Sequences

This will display a dialog listing all the sequences in the alignment. Next to each sequence is a checkbox which is used for selecting which sequences, the annotation should be copied to. Click **Copy** to copy the annotation.

If you wish to copy all annotations on the sequence, click the **Copy All Annotations to other Sequences**.

22.3.5 Move sequences up and down

Sequences can be moved up and down in the alignment:

drag the name of the sequence up or down

When you move the mouse pointer over the label, the pointer will turn into a vertical arrow indicating that the sequence can be moved.

The sequences can also be sorted automatically to let you save time moving the sequences around. To sort the sequences alphabetically:

Right-click the name of a sequence | Sort Sequences Alphabetically

If you change the Sequence name (in the **Sequence Layout** view preferences), you will have to ask the program to sort the sequences again.

The sequences can also be sorted by similarity, grouping similar sequences together:

Right-click the name of a sequence | Sort Sequences by Similarity

22.3.6 Delete, rename and add sequences

Sequences can be removed from the alignment by right-clicking the label of a sequence:

right-click label | Delete Sequence

This can be undone by clicking **Undo** () in the Toolbar.

If you wish to delete several sequences, you can check all the sequences, right-click and choose

Delete Marked Sequences. To show the checkboxes, you first have to click the **Show Selection Boxes** in the **Side Panel**.

A sequence can also be renamed:

right-click label | Rename Sequence

This will show a dialog, letting you rename the sequence. This will not affect the sequence that the alignment is based on.

Extra sequences can be added to the alignment by creating a new alignment where you select the current alignment and the extra sequences (see section 22.1).

The same procedure can be used for joining two alignments.

22.3.7 Realign selection

If you have created an alignment, it is possible to realign a part of it, leaving the rest of the alignment unchanged:

select a part of the alignment to realign | right-click the selection | Realign selection

This will open **Step 2** in the "Create alignment" dialog, allowing you to set the parameters for the realignment (see section 22.1).

It is possible for an alignment to become shorter or longer as a result of the realignment of a region. This is because gaps may have to be inserted in, or deleted from, the sequences not selected for realignment. This will only occur for entire columns of gaps in these sequences, ensuring that their relative alignment is unchanged.

Realigning a selection is a very powerful tool for editing alignments in several situations:

- **Removing changes.** If you change the alignment in a specific region by hand, you may end up being unhappy with the result. In this case you may of course undo your edits, but another option is to select the region and realign it.
- **Adjusting the number of gaps.** If you have a region in an alignment which has too many gaps in your opinion, you can select the region and realign it. By choosing a relatively high gap cost you will be able to reduce the number of gaps.
- **Combine with fixpoints.** If you have an alignment where two residues are not aligned, but you know that they should have been. You can now set an alignment fixpoint on each of the two residues, select the region and realign it using the fixpoints. Now, the two residues are aligned with each other and everything in the selected region around them is adjusted to accommodate this change.

22.4 Join alignments

CLC Main Workbench can join several alignments into one. This feature can for example be used to construct "supergenes" for phylogenetic inference by joining alignments of several disjoint genes into one spliced alignment. Note, that when alignments are joined, all their annotations are carried over to the new spliced alignment.

Alignments can be joined by:

select alignments to join | **Toolbox in the Menu Bar** | **Alignments and Trees** (📁) | **Join Alignments** (⌘+J)

or **select alignments to join** | **right-click either selected alignment** | **Toolbox** | **Alignments and Trees** (📁) | **Join Alignments** (⌘+J)

This opens the dialog shown in figure 22.10.

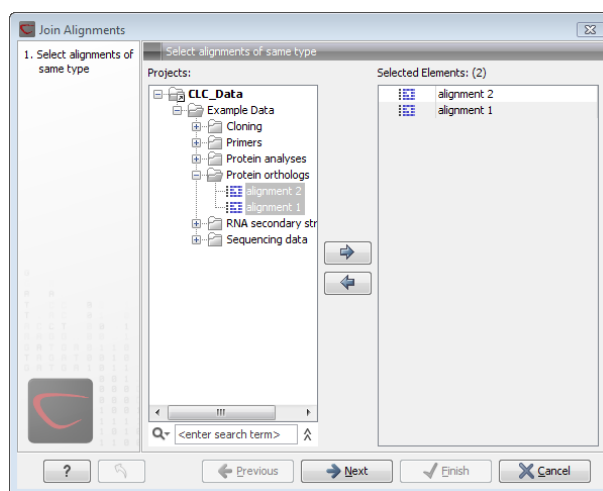

Figure 22.10: Selecting two alignments to be joined.

If you have selected some alignments before choosing the Toolbox action, they are now listed in the **Selected Elements** window of the dialog. Use the arrows to add or remove alignments from the selected elements. Click **Next** opens the dialog shown in figure 22.11.

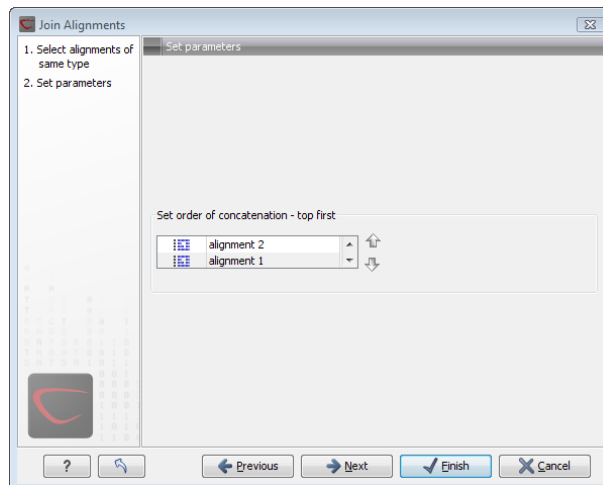

Figure 22.11: Selecting order of concatenation.

To adjust the order of concatenation, click the name of one of the alignments, and move it up or down using the arrow buttons.

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**. The result is seen in figure 22.12.

Figure 22.12: The joining of the alignments result in one alignment containing rows of sequences corresponding to the number of uniquely named sequences in the joined alignments.

22.4.1 How alignments are joined

Alignments are joined by considering the sequence names in the individual alignments. If two sequences from different alignments have identical names, they are considered to have the same origin and are thus joined. Consider the joining of alignments A and B. If a sequence named "in-A-and-B" is found in both A and B, the spliced alignment will contain a sequence named "in-A-and-B" which represents the characters from A and B joined in direct extension of each other. If a sequence with the name "in-A-not-B" is found in A but not in B, the spliced alignment will contain a sequence named "in-A-not-B". The first part of this sequence will contain the characters from A, but since no sequence information is available from B, a number of gap characters will be added to the end of the sequence corresponding to the number of residues in B. Note, that the function does not require that the individual alignments contain an equal number of sequences.

22.5 Pairwise comparison

For a given set of aligned sequences (see chapter 22) it is possible make a pairwise comparison in which each pair of sequences are compared to each other. This provides an overview of the diversity among the sequences in the alignment.

In *CLC Main Workbench* this is done by creating a comparison table:

Toolbox in the Menu Bar | Alignments and Trees (📁) | Pairwise Comparison (📊)

or **right-click alignment in Navigation Area | Toolbox | Alignments and Trees (📁) | Pairwise Comparison (📊)**

This opens the dialog displayed in figure 22.13:

If an alignment was selected before choosing the Toolbox action, this alignment is now listed in the **Selected Elements** window of the dialog. Use the arrows to add or remove elements from the **Navigation Area**. Click **Next** to adjust parameters.

22.5.1 Pairwise comparison on alignment selection

A pairwise comparison can also be performed for a selected part of an alignment:

right-click on an alignment selection | Pairwise Comparison (📊)

This leads directly to the dialog described in the next section.

Figure 22.13: Creating a pairwise comparison table.

22.5.2 Pairwise comparison parameters

There are four kinds of comparison that can be made between the sequences in the alignment, as shown in figure 22.14.

Figure 22.14: Adjusting parameters for pairwise comparison.

- **Gaps** Calculates the number of alignment positions where one sequence has a gap and the other does not.
- **Identities** Calculates the number of identical alignment positions to overlapping alignment positions between the two sequences.
- **Differences** Calculates the number of alignment positions where one sequence is different from the other. This includes gap differences as in the Gaps comparison.
- **Distance** Calculates the Jukes-Cantor distance between the two sequences. This number is given as the Jukes-Cantor correction of the proportion between identical and overlapping alignment positions between the two sequences.
- **Percent identity** Calculates the percentage of identical residues in alignment positions to overlapping alignment positions between the two sequences.

Click **Next** if you wish to adjust how to handle the results (see section 9.2). If not, click **Finish**.

22.5.3 The pairwise comparison table

The table shows the results of selected comparisons (see an example in figure 22.15). Since comparisons are often symmetric, the table can show the results of two comparisons at the same time, one in the upper-right and one in the lower-left triangle.

	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 22.15: A pairwise comparison table.

The following settings are present in the side panel:

- **Contents**

- **Upper comparison.** Selects the comparison to show in the upper triangle of the table
- **Upper comparison gradient.** Selects the color gradient to use for the upper triangle.
- **Lower comparison** Selects the comparison to show in the lower triangle. Choose the same comparison as in the upper triangle to show all the results of an asymmetric comparison.
- **Lower comparison gradient.** Selects the color gradient to use for the lower triangle.
- **Diagonal from upper.** Use this setting to show the diagonal results from the upper comparison.
- **Diagonal from lower.** Use this setting to show the diagonal results from the lower comparison.
- **No Diagonal.** Leaves the diagonal table entries blank.

- **Layout**

- **Lock headers.** Locks the sequence labels and table headers when scrolling the table.
- **Sequence label.** Changes the sequence labels.

- **Text format**

- **Text size.** Changes the size of the table and the text within it.
- **Font.** Changes the font in the table.
- **Bold.** Toggles the use of boldface in the table.

22.6 Bioinformatics explained: Multiple alignments

Multiple alignments are at the core of bioinformatical analysis. Often the first step in a chain of bioinformatical analyses is to construct a multiple alignment of a number of homologs DNA or protein sequences. However, despite their frequent use, the development of multiple alignment algorithms remains one of the algorithmically most challenging areas in bioinformatical research.

Constructing a multiple alignment corresponds to developing a hypothesis of how a number of sequences have evolved through the processes of character substitution, insertion and deletion. The input to multiple alignment algorithms is a number of homologous sequences i.e. sequences that share a common ancestor and most often also share molecular function. The generated alignment is a table (see figure 22.16) where each row corresponds to an input sequence and each column corresponds to a position in the alignment. An individual column in this table represents residues that have all diverged from a common ancestral residue. Gaps in the table (commonly represented by a '-') represent positions where residues have been inserted or deleted and thus do not have ancestral counterparts in all sequences.

22.6.1 Use of multiple alignments

Once a multiple alignment is constructed it can form the basis for a number of analyses:

- The phylogenetic relationship of the sequences can be investigated by tree-building methods based on the alignment.
- Annotation of functional domains, which may only be known for a subset of the sequences, can be transferred to aligned positions in other un-annotated sequences.
- Conserved regions in the alignment can be found which are prime candidates for holding functionally important sites.
- Comparative bioinformatical analysis can be performed to identify functionally important regions.

22.6.2 Constructing multiple alignments

Whereas the optimal solution to the pairwise alignment problem can be found in reasonable time, the problem of constructing a multiple alignment is much harder.

The first major challenge in the multiple alignment procedure is how to rank different alignments i.e. which *scoring function* to use. Since the sequences have a shared history they are correlated through their *phylogeny* and the scoring function should ideally take this into account. Doing so is, however, not straightforward as it increases the number of model parameters considerably.

Figure 22.16: The tabular format of a multiple alignment of 24 Hemoglobin protein sequences. Sequence names appear at the beginning of each row and the residue position is indicated by the numbers at the top of the alignment columns. The level of sequence conservation is shown on a color scale with blue residues being the least conserved and red residues being the most conserved.

It is therefore commonplace to either ignore this complication and assume sequences to be unrelated, or to use heuristic corrections for shared ancestry.

The second challenge is to find the optimal alignment given a scoring function. For pairs of sequences this can be done by *dynamic programming* algorithms, but for more than three sequences this approach demands too much computer time and memory to be feasible.

A commonly used approach is therefore to do *progressive alignment* [Feng and Doolittle, 1987] where multiple alignments are built through the successive construction of pairwise alignments. These algorithms provide a good compromise between time spent and the quality of the resulting alignment

Presently, the most exciting development in multiple alignment methodology is the construction of *statistical alignment* algorithms [Hein, 2001], [Hein et al., 2000]. These algorithms employ a scoring function which incorporates the underlying phylogeny and use an explicit stochastic model of molecular evolution which makes it possible to compare different solutions in a statistically rigorous way. The optimization step, however, still relies on dynamic programming and practical use of these algorithms thus awaits further developments.

CLC Main Workbench offers different ways of inferring phylogenetic trees. The first part of this chapter will briefly explain the different ways of inferring trees in *CLC Main Workbench*. The second part, "Bioinformatics explained", will give a more general introduction to the concept of phylogeny and the associated bioinformatics methods.

23.1 Inferring phylogenetic trees

For a given set of aligned sequences (see chapter 22) it is possible to infer their evolutionary relationships. In *CLC Main Workbench* this may be done either by using a distance based method (see "Bioinformatics explained" in section 23.2.) or by using the statistically founded maximum likelihood (ML) approach [Felsenstein, 1981]. Both approaches generate a phylogenetic tree. The tools are found in:

Toolbox | Alignments and Trees 

To generate a distance-based phylogenetic tree choose:

Create Tree 

and to generate a maximum likelihood based phylogenetic tree choose:

Maximum Likelihood Phylogeny 

In both cases the dialog displayed in figure 23.1 will be opened:

Figure 23.1: Creating a Tree.

If an alignment was selected before choosing the Toolbox action, this alignment is now listed in the **Selected Elements** window of the dialog. Use the arrows to add or remove elements from the **Navigation Area**. Click **Next** to adjust parameters.

23.1.1 Phylogenetic tree parameters

Distance-based methods

Figure 23.2: Adjusting parameters for distance-based methods.

Figure 23.2 shows the parameters that can be set for the distance-based methods:

The distance-based methods make use of Jukes-Cantor distances.

- Algorithms

- The **UPGMA** method assumes that evolution has occurred at a constant rate in the different lineages. This means that a root of the tree is also estimated.
- The **neighbor joining** method builds a tree where the evolutionary rates are free to differ in different lineages. *CLC Main Workbench* always draws trees with roots for practical reasons, but with the neighbor joining method, no particular biological hypothesis is

postulated by the placement of the root. Figure 23.3 shows the difference between the two methods.

- To evaluate the reliability of the inferred trees, *CLC Main Workbench* allows the option of doing a **bootstrap** analysis. A bootstrap value will be attached to each branch, and this value is a measure of the confidence in this branch. The number of replicates in the bootstrap analysis can be adjusted in the wizard. The default value is 100.

For a more detailed explanation, see "Bioinformatics explained" in section 23.2.

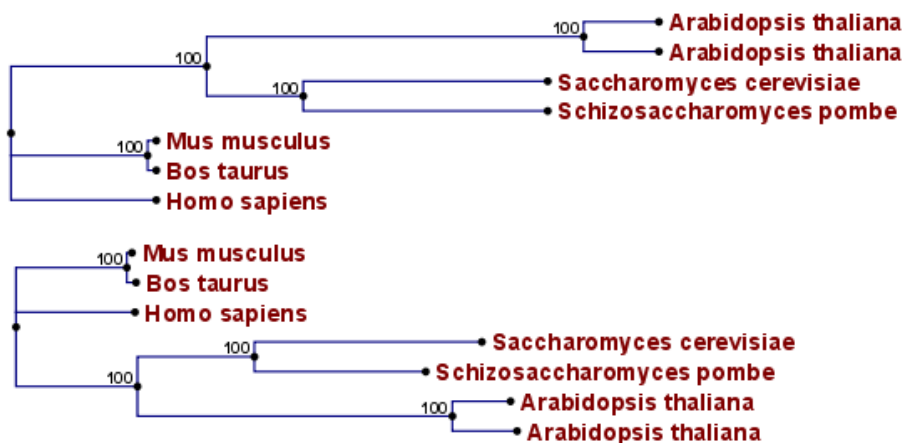

Figure 23.3: Method choices for phylogenetic inference. The bottom shows a tree found by neighbor joining, while the top shows a tree found by UPGMA. The latter method assumes that the evolution occurs at a constant rate in different lineages.

Maximum likelihood phylogeny

Figure 23.4: Adjusting parameters for ML phylogeny

Figure 23.4 shows the parameters that can be set for the ML phylogenetic tree reconstruction:

- **Starting tree:** the user is asked to specify a starting tree for the tree reconstruction. There are three possibilities

- Neighbor joining
 - UPGMA
 - Use tree from file.
- **Select substitution model:** *CLC Main Workbench* allows maximum likelihood tree estimation to be performed under the assumption of one of four substitution models: the Jukes Cantor [Jukes and Cantor, 1969], the Kimura 80 [Kimura, 1980], the HKY [Hasegawa et al., 1985] and the GTR (also known as the REV model) [Yang, 1994a] models. All models are time-reversible. The JC and K80 models assume equal base frequencies and the HKY and GTR models allow the frequencies of the four bases to differ (they will be estimated by the observed frequencies of the bases in the alignment). In the JC model all substitutions are assumed to occur at equal rates, in the K80 and HKY models transition and transversion rates are allowed to differ. The GTR model is the general time reversible model and allows all substitutions to occur at different rates. In case of the K80 and HKY models the user may set a transition/transversion ratio value which will be used as starting value or fixed, depending on the level of estimation chosen by the user (see below). For the substitution rate matrices describing the substitution models we use the parametrization of Yang [Yang, 1994a].
 - **Rate variation:** in *CLC Main Workbench* substitution rates may be allowed to differ among the individual nucleotide sites in the alignment by selecting the **include rate variation** box. When selected, the discrete gamma model of Yang [Yang, 1994b] is used to model rate variation among sites. The number of categories used in the discretization of the gamma distribution as well as the gamma distribution parameter may be adjusted by the user (as the gamma distribution is restricted to have mean 1, there is only one parameter in the distribution)
 - **Estimation** estimation is done according to the maximum likelihood principle, that is, a search is performed for the values of the free parameters in the model assumed that results in the highest likelihood of the observed alignment [Felsenstein, 1981]. By ticking the **estimate substitution rate parameters** box, maximum likelihood values of the free parameters in the rate matrix describing the assumed substitution model are found. If the **Estimate topology** box is selected, a search in the space of tree topologies for that which best explains the alignment is performed. If left un-ticked, the starting topology is kept fixed at that of the starting tree. The **Estimate Gamma distribution parameter** is active if rate variation has been included in the model and in this case allows estimation of the Gamma distribution parameter to be switched on or off. If the box is left un-ticked, the value is fixed at that given in the **Rate variation** part. In the absence of rate variation estimation of substitution parameters and branch lengths are carried out according to the expectation maximization algorithm [Dempster et al., 1977]. With rate variation the maximization algorithm is performed. The topology space is searched according to the PHYML method [Guindon and Gascuel, 2003], allowing efficient search and estimation of large phylogenies. **Branch lengths are given in terms of expected numbers of substitutions per nucleotide site.**

23.1.2 Tree View Preferences

The **Tree View** preferences are these:

- **Text format.** Changes the text format for all of the nodes the tree contains.
 - **Text size.** The size of the text representing the nodes can be modified in tiny, small, medium, large or huge.
 - **Font.** Sets the font of the text of all nodes
 - **Bold.** Sets the text bold if enabled.

- **Tree Layout.** Different layouts for the tree.
 - **Node symbol.** Changes the symbol of nodes into box, dot, circle or none if you don't want a node symbol.
 - **Layout.** Displays the tree layout as standard or topology.
 - **Show internal node labels.** This allows you to see labels for the internal nodes. Initially, there are no labels, but right-clicking a node allows you to type a label.
 - **Label color.** Changes the color of the labels on the tree nodes.
 - **Branch label color.** Modifies the color of the labels on the branches.
 - **Node color.** Sets the color of all nodes.
 - **Line color.** Alters the color of all lines in the tree.

- **Labels.** Specifies the text to be displayed in the tree.
 - **Nodes.** Sets the annotation of all nodes either to name or to species.
 - **Branches.** Changes the annotation of the branches to bootstrap, length or none if you don't want annotation on branches.

Note! Dragging in a tree will change it. You are therefore asked if you want to save this tree when the **Tree View** is closed.

You may select part of a **Tree** by clicking on the nodes that you want to select.

Right-click a selected node opens a menu with the following options:

- Set root above node (defines the root of the tree to be just above the selected node).
- Set root at this node (defines the root of the tree to be at the selected node).
- Toggle collapse (collapses or expands the branches below the node).
- Change label (allows you to label or to change the existing label of a node).
- Change branch label (allows you to change the existing label of a branch).

You can also relocate leaves and branches in a tree or change the length. It is possible to modify the text on the unit measurement at the bottom of the tree view by right-clicking the text. In this way you can specify a unit, e.g. "years".

Branch lengths are given in terms of expected numbers of substitutions per site.

Note! To drag branches of a tree, you must first click the node one time, and then click the node again, and this time hold the mouse button.

In order to change the representation:

- Rearrange leaves and branches by
Select a leaf or branch | Move it up and down (Hint: The mouse turns into an arrow pointing up and down)
- Change the length of a branch by
Select a leaf or branch | Press Ctrl | Move left and right (Hint: The mouse turns into an arrow pointing left and right)

Alter the preferences in the **Side Panel** for changing the presentation of the tree.

23.2 Bioinformatics explained: phylogenetics

Phylogenetics describes the taxonomical classification of organisms based on their evolutionary history i.e. their *phylogeny*. Phylogenetics is therefore an integral part of the science of *systematics* that aims to establish the phylogeny of organisms based on their characteristics. Furthermore, phylogenetics is central to evolutionary biology as a whole as it is the condensation of the overall paradigm of how life arose and developed on earth.

23.2.1 The phylogenetic tree

The evolutionary hypothesis of a phylogeny can be graphically represented by a phylogenetic tree.

Figure 23.5 shows a proposed phylogeny for the great apes, *Hominidae*, taken in part from Purvis [Purvis, 1995]. The tree consists of a number of nodes (also termed vertices) and branches (also termed edges). These nodes can represent either an individual, a species, or a higher grouping and are thus broadly termed taxonomical units. In this case, the terminal nodes (also called leaves or tips of the tree) represent extant species of *Hominidae* and are the *operational taxonomical units* (OTUs). The internal nodes, which here represent extinct common ancestors of the great apes, are termed *hypothetical taxonomical units* since they are not directly observable.

Figure 23.5: A proposed phylogeny of the great apes (*Hominidae*). Different components of the tree are marked, see text for description.

The ordering of the nodes determine the tree *topology* and describes how lineages have diverged over the course of evolution. The branches of the tree represent the amount of evolutionary divergence between two nodes in the tree and can be based on different measurements. A tree is completely specified by its topology and the set of all edge lengths.

The phylogenetic tree in figure 23.5 is rooted at the most recent common ancestor of all *Hominidae* species, and therefore represents a hypothesis of the direction of evolution e.g. that

the common ancestor of gorilla, chimpanzee and man existed before the common ancestor of chimpanzee and man. In contrast, an unrooted tree would represent relationships without assumptions about ancestry.

23.2.2 Modern usage of phylogenies

Besides evolutionary biology and systematics the inference of phylogenies is central to other areas of research.

As more and more genetic diversity is being revealed through the completion of multiple genomes, an active area of research within bioinformatics is the development of comparative machine learning algorithms that can simultaneously process data from multiple species [Siepel and Haussler, 2004]. Through the comparative approach, valuable evolutionary information can be obtained about which amino acid substitutions are functionally tolerant to the organism and which are not. This information can be used to identify substitutions that affect protein function and stability, and is of major importance to the study of proteins [Knudsen and Miyamoto, 2001]. Knowledge of the underlying phylogeny is, however, paramount to comparative methods of inference as the phylogeny describes the underlying correlation from shared history that exists between data from different species.

In molecular epidemiology of infectious diseases, phylogenetic inference is also an important tool. The very fast substitution rate of microorganisms, especially the RNA viruses, means that these show substantial genetic divergence over the time-scale of months and years. Therefore, the phylogenetic relationship between the pathogens from individuals in an epidemic can be resolved and contribute valuable epidemiological information about transmission chains and epidemiologically significant events [Leitner and Albert, 1999], [Forsberg et al., 2001].

23.2.3 Reconstructing phylogenies from molecular data

Traditionally, phylogenies have been constructed from morphological data, but following the growth of genetic information it has become common practice to construct phylogenies based on molecular data, known as *molecular phylogeny*. The data is most commonly represented in the form of DNA or protein sequences, but can also be in the form of e.g. restriction fragment length polymorphism (RFLP).

Methods for constructing molecular phylogenies can be distance based or character based.

Distance based methods

Two common algorithms, both based on pairwise distances, are the UPGMA and the Neighbor Joining algorithms. Thus, the first step in these analyses is to compute a matrix of pairwise distances between OTUs from their sequence differences. To correct for multiple substitutions it is common to use distances corrected by a model of molecular evolution such as the Jukes-Cantor model [Jukes and Cantor, 1969].

UPGMA. A simple but popular clustering algorithm for distance data is Unweighted Pair Group Method using Arithmetic averages (UPGMA) ([Michener and Sokal, 1957], [Sneath and Sokal, 1973]). This method works by initially having all sequences in separate clusters and continuously joining these. The tree is constructed by considering all initial clusters as leaf nodes in the tree, and each time two clusters are joined, a node is added to the tree as the parent of the two chosen nodes. The clusters to be joined are chosen as those with minimal pairwise distance. The branch lengths are set corresponding to the distance between clusters, which is calculated

as the average distance between pairs of sequences in each cluster.

The algorithm assumes that the distance data has the so-called *molecular clock* property i.e. the divergence of sequences occur at the same constant rate at all parts of the tree. This means that the leaves of UPGMA trees all line up at the extant sequences and that a root is estimated as part of the procedure.

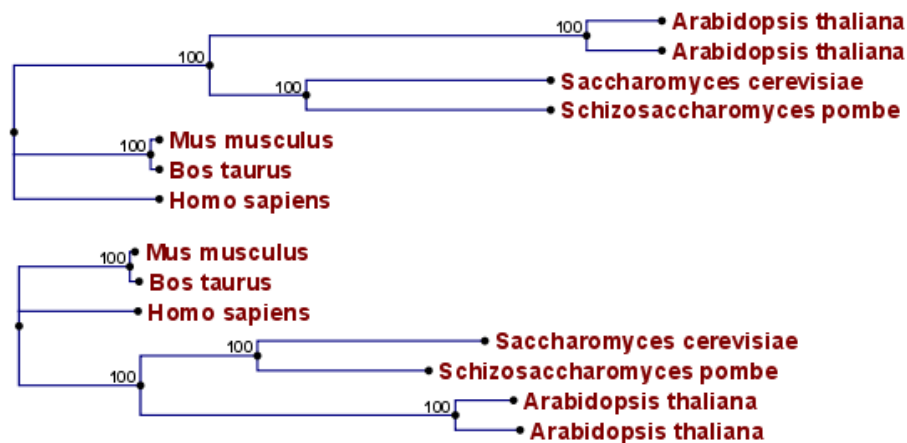

Figure 23.6: Algorithm choices for phylogenetic inference. The bottom shows a tree found by the neighbor joining algorithm, while the top shows a tree found by the UPGMA algorithm. The latter algorithm assumes that the evolution occurs at a constant rate in different lineages.

Neighbor Joining. The neighbor joining algorithm, [Saitou and Nei, 1987], on the other hand, builds a tree where the evolutionary rates are free to differ in different lineages, i.e., the tree does not have a particular root. Some programs always draw trees with roots for practical reasons, but for neighbor joining trees, no particular biological hypothesis is postulated by the placement of the root. The method works very much like UPGMA. The main difference is that instead of using pairwise distance, this method subtracts the distance to all other nodes from the pairwise distance. This is done to take care of situations where the two closest nodes are not neighbors in the "real" tree. The neighbor join algorithm is generally considered to be fairly good and is widely used. Algorithms that improves its cubic time performance exist. The improvement is only significant for quite large datasets.

Character based methods. Whereas the distance based methods compress all sequence information into a single number, the character based methods attempt to infer the phylogeny based on all the individual characters (nucleotides or amino acids).

Parsimony. In parsimony based methods a number of sites are defined which are informative about the topology of the tree. Based on these, the best topology is found by minimizing the number of substitutions needed to explain the informative sites. Parsimony methods are not based on explicit evolutionary models.

Maximum Likelihood. Maximum likelihood and Bayesian methods (see below) are probabilistic methods of inference. Both have the pleasing properties of using explicit models of molecular evolution and allowing for rigorous statistical inference. However, both approaches are very computer intensive.

A stochastic model of molecular evolution is used to assign a probability (likelihood) to each phylogeny, given the sequence data of the OTUs. Maximum likelihood inference [Felsenstein,

1981] then consists of finding the tree which assign the highest probability to the data.

Bayesian inference. The objective of Bayesian phylogenetic inference is not to infer a single "correct" phylogeny, but rather to obtain the full posterior probability distribution of all possible phylogenies. This is obtained by combining the likelihood and the prior probability distribution of evolutionary parameters. The vast number of possible trees means that bayesian phylogenetics must be performed by approximative Monte Carlo based methods. [Larget and Simon, 1999], [Yang and Rannala, 1997].

23.2.4 Interpreting phylogenies

Bootstrap values

A popular way of evaluating the reliability of an inferred phylogenetic tree is bootstrap analysis. The first step in a bootstrap analysis is to re-sample the alignment columns with replacement. I.e., in the re-sampled alignment, a given column in the original alignment may occur two or more times, while some columns may not be represented in the new alignment at all. The re-sampled alignment represents an estimate of how a different set of sequences from the same genes and the same species may have evolved on the same tree.

If a new tree reconstruction on the re-sampled alignment results in a tree similar to the original one, this increases the confidence in the original tree. If, on the other hand, the new tree looks very different, it means that the inferred tree is unreliable. By re-sampling a number of times it is possibly to put reliability weights on each internal branch of the inferred tree. If the data was bootstrapped a 100 times, a bootstrap score of 100 means that the corresponding branch occurs in all 100 trees made from re-sampled alignments. Thus, a high bootstrap score is a sign of greater reliability.

Ribonucleic acid (RNA) is a nucleic acid polymer that plays several important roles in the cell.

As for proteins, the three dimensional shape of an RNA molecule is important for its molecular function. A number of tertiary RNA structures are known from crystallography but de novo prediction of tertiary structures is not possible with current methods. However, as for proteins RNA tertiary structures can be characterized by secondary structural elements which are hydrogen bonds within the molecule that form several recognizable "domains" of secondary structure like stems, hairpin loops, bulges and internal loops. A large part of the functional information is thus

contained in the secondary structure of the RNA molecule, as shown by the high degree of base-pair conservation observed in the evolution of RNA molecules.

Computational prediction of RNA secondary structure is a well defined problem and a large body of work has been done to refine prediction algorithms and to experimentally estimate the relevant biological parameters.

In *CLC Main Workbench* we offer the user a number of tools for analyzing and displaying RNA structures. These include:

- Secondary structure prediction using state-of-the-art algorithms and parameters
- Calculation of full partition function to assign probabilities to structural elements and hypotheses
- Scanning of large sequences to find local structure signal
- Inclusion of experimental constraints to the folding process
- Advanced viewing and editing of secondary structures and structure information

24.1 RNA secondary structure prediction

CLC Main Workbench uses a minimum free energy (MFE) approach to predict RNA secondary structure. Here, the stability of a given secondary structure is defined by the amount of free energy used (or released) by its formation. The more negative free energy a structure has, the more likely is its formation since more stored energy is released by the event. Free energy contributions are considered additive, so the total free energy of a secondary structure can be calculated by adding the free energies of the individual structural elements. Hence, the task of the prediction algorithm is to find the secondary structure with the minimum free energy. As input to the algorithm empirical energy parameters are used. These parameters summarize the free energy contribution associated with a large number of structural elements. A detailed structure overview can be found in [24.5](#).

In *CLC Main Workbench*, structures are predicted by a modified version of Professor Michael Zukers well known algorithm [[Zuker, 1989b](#)] which is the algorithm behind a number of RNA-folding packages including MFOLD. Our algorithm is a dynamic programming algorithm for free energy minimization which includes free energy increments for coaxial stacking of stems when they are either adjacent or separated by a single mismatch. The thermodynamic energy parameters used are from the latest Mfold version 3, see <http://www.bioinfo.rpi.edu/~zukerm/rna/energy/>.

24.1.1 Selecting sequences for prediction

Secondary structure prediction can be accessed in the **Toolbox**:

Toolbox | RNA Structure () | Predict Secondary Structure ()

This opens the dialog shown in figure [24.1](#).

If you have selected sequences before choosing the Toolbox action, they are now listed in the **Selected Elements** window of the dialog. Use the arrows to add or remove sequences or

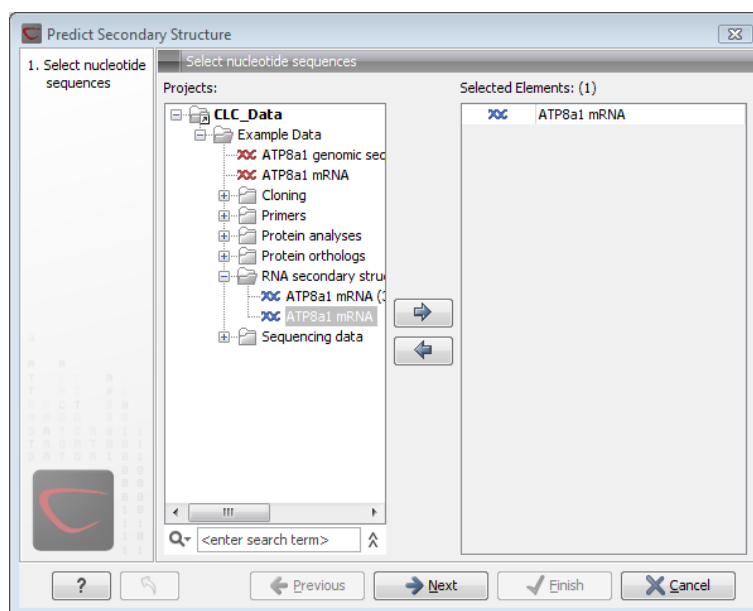

Figure 24.1: Selecting RNA or DNA sequences for structure prediction (DNA is folded as if it were RNA).

sequence lists from the selected elements. You can use both DNA and RNA sequences - DNA will be folded as if it were RNA. Click **Next** to adjust secondary structure prediction parameters. Clicking **Next** opens the dialog shown in figure 24.2.

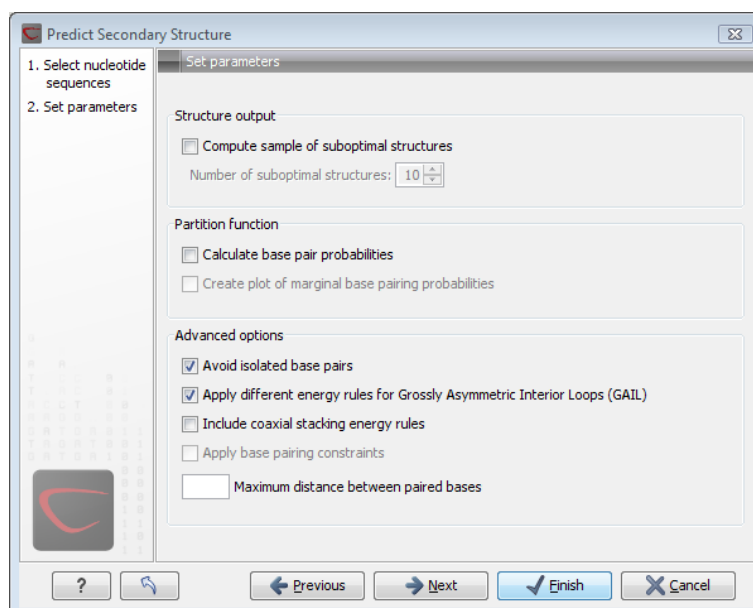

Figure 24.2: Adjusting parameters for secondary structure prediction.

24.1.2 Structure output

The predict secondary structure algorithm always calculates the minimum free energy structure of the input sequence. In addition to this, it is also possible to compute a sample of suboptimal structures by ticking the checkbox labeled **Compute sample of suboptimal structures**. Subsequently, you can specify how many structures to include in the output. The algorithm then

iterates over all permissible canonical base pairs and computes the minimum free energy and associated secondary structure constrained to contain a specified base pair. These structures are then sorted by their minimum free energy and the most optimal are reported given the specified number of structures. Note, that two different sub-optimal structures can have the same minimum free energy. Further information about suboptimal folding can be found in [Zuker, 1989a].

24.1.3 Partition function

The predicted minimum free energy structure gives a point-estimate of the structural conformation of an RNA molecule. However, this procedure implicitly assumes that the secondary structure is at equilibrium, that there is only a single accessible structure conformation, and that the parameters and model of the energy calculation are free of errors.

Obvious deviations from these assumptions make it clear that the predicted MFE structure may deviate somewhat from the actual structure assumed by the molecule. This means that rather than looking at the MFE structure it may be informative to inspect statistical properties of the structural landscape to look for general structural properties which seem to be robust to minor variations in the total free energy of the structure (see [Mathews et al., 2004]).

To this end *CLC Main Workbench* allows the user to calculate the complete secondary structure partition function using the algorithm described in [Mathews et al., 2004] which is an extension of the seminal work by [McCaskill, 1990].

There are two options regarding the partition function calculation:

- **Calculate base pair probabilities.** This option invokes the partition function calculation and calculates the marginal probabilities of all possible base pairs and the the marginal probability that any single base is unpaired.
- **Create plot of marginal base pairing probabilities.** This creates a plot of the marginal base pair probability of all possible base pairs as shown in figure 24.3.

The marginal probabilities of base pairs and of bases being unpaired are distinguished by colors which can be displayed in the normal sequence view using the **Side Panel** - see section 24.2.3 and also in the secondary structure view. An example is shown in figure 24.4. Furthermore, the marginal probabilities are accessible from tooltips when hovering over the relevant parts of the structure.

24.1.4 Advanced options

The free energy minimization algorithm includes a number of advanced options:

- **Avoid isolated base pairs.** The algorithm filters out isolated base pairs (i.e. stems of length 1).
- **Apply different energy rules for Grossly Asymmetric Interior Loops (GAIL).** Compute the minimum free energy applying different rules for Grossly Asymmetry Interior Loops (GAIL). A Grossly Asymmetry Interior Loop (GAIL) is an interior loop that is $1 \times n$ or $n \times 1$ where $n > 2$ (see <http://www.bioinfo.rpi.edu/~zukerm/lectures/RNAfold-html/rnafold-print.pdf>).

Figure 24.3: The marginal base pair probability of all possible base pairs.

- **Include coaxial stacking energy rules.** Include free energy increments of coaxial stacking for adjacent helices [Mathews et al., 2004].
- **Apply base pairing constraints.** With base pairing constraints, you can easily add experimental constraints to your folding algorithm. When you are computing suboptimal structures, it is not possible to apply base pair constraints. The possible base pairing constraints are:
 - Force two equal length intervals to form a stem.
 - Prohibit two equal length intervals to form a stem.
 - Prohibit all nucleotides in a selected region to be a part of a base pair.

Base pairing constraints have to be added to the sequence before you can use this option - see below.

- **Maximum distance between paired bases.** Forces the algorithms to only consider RNA structures of a given upper length by setting a maximum distance between the base pair that opens a structure.

Specifying structure constraints

Structure constraints can serve two purposes in *CLC Main Workbench*: they can act as experimental constraints imposed on the MFE structure prediction algorithm or they can form a structure hypothesis to be evaluated using the partition function (see section 24.1.3).

To force two regions to form a stem, open a normal sequence view and:

Select the two regions you want to force by pressing Ctrl while selecting - (use ⌘ on Mac) | right-click the selection | Add Structure Prediction Constraints| Force Stem Here

This will add an annotation labeled "Forced Stem" to the sequence (see figure 24.5).

Figure 24.4: Marginal probability of base pairs shown in linear view (top) and marginal probability of being unpaired shown in the secondary structure 2D view (bottom).

Figure 24.5: Force a stem of the selected bases.

Using this procedure to add base pairing constraints will force the algorithm to compute minimum free energy and structure with a stem in the selected region. The two regions must be of equal length.

To *prohibit* two regions to form a stem, open the sequence and:

Select the two regions you want to prohibit by pressing Ctrl while selecting - (use ⌘ on Mac) | right-click the selection | Add Structure Prediction Constraints | Prohibit Stem Here

This will add an annotation labeled "Prohibited stem" to the sequence (see figure 24.6).

Figure 24.6: Prohibit the selected bases from forming a stem.

Using this procedure to add base pairing constraints will force the algorithm to compute minimum free energy and structure without a stem in the selected region. Again, the two selected regions must be of equal length.

To prohibit a region to be part of *any* base pair, open the sequence and:

Select the bases you don't want to base pair | right-click the selection | Add Structure Prediction Constraints | Prohibit From Forming Base Pairs

This will add an annotation labeled "No base pairs" to the sequence, see 24.7.

Figure 24.7: Prohibiting any of the selected base from pairing with other bases.

Using this procedure to add base pairing constraints will force the algorithm to compute minimum free energy and structure without a base pair containing any residues in the selected region.

When you click **Predict secondary structure** (⚙) and click **Next**, check **Apply base pairing constraints** in order to force or prohibit stem regions or prohibit regions from forming base pairs.

You can add multiple base pairing constraints, e.g. simultaneously adding forced stem regions and prohibited stem regions and prohibit regions from forming base pairs.

24.1.5 Structure as annotation

You can choose to add the elements of the best structure as annotations (see figure 24.8).

Figure 24.8: Annotations added for each structure element.

This makes it possible to use the structure information in other analysis in the *CLC Main Workbench*. You can e.g. align different sequences and compare their structure predictions.

Note that possibly existing structure annotation will be removed when a new structure is calculated and added as annotations.

If you generate multiple structures, only the best structure will be added as annotations. If you wish to add one of the sub-optimal structures as annotations, this can be done from the **Show Secondary Structure Table** (⚙) described in section 24.2.2.

24.2 View and edit secondary structures

When you predict RNA secondary structure (see section 24.1), the resulting predictions are attached to the sequence and can be shown as:

- Annotations in the ordinary sequence views (Linear sequence view (🔍), Annotation table (📄) etc. This is only possible if this has been chosen in the dialog in figure 24.2. See an example in figure 24.8.
- Symbolic representation below the sequence (see section 24.2.3).
- A graphical view of the secondary structure (see section 24.2.1).
- A tabular view of the energy contributions of the elements in the structure. If more than one structure have been predicted, the table is also used to switch between the structures shown in the graphical view. The table is described in section 24.2.2.

24.2.1 Graphical view and editing of secondary structure

To show the secondary view of an already open sequence, click the **Show Secondary Structure 2D View** (🔍) button at the bottom of the sequence view.

If the sequence is not open, click **Show** (📄) and select **Secondary Structure 2D View** (🔍).

This will open a view similar to the one shown in figure 24.9.

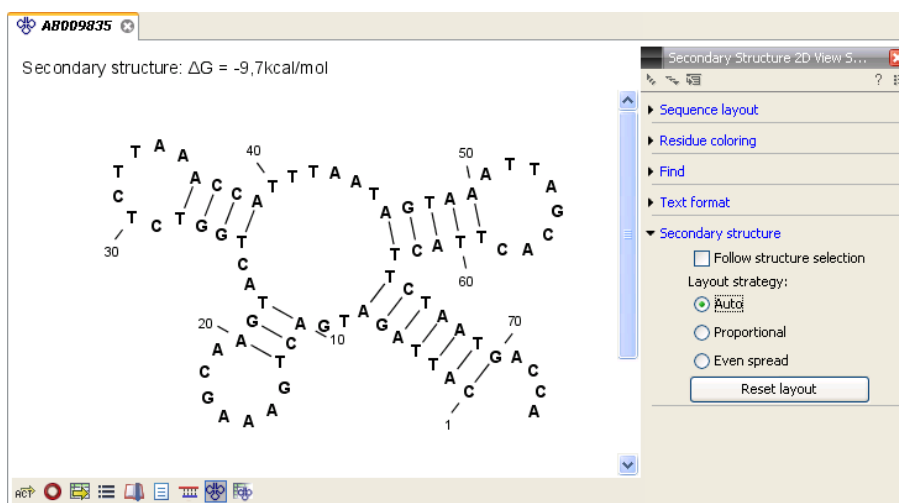

Figure 24.9: The secondary structure view of an RNA sequence zoomed in.

Like the normal sequence view, you can use **Zoom in** (🔍) and **Zoom out** (🔍). Zooming in will reveal the residues of the structure as shown in figure 24.9. For large structures, zooming out will give you an overview of the whole structure.

Side Panel settings

The settings in the **Side Panel** are a subset of the settings in the normal sequence view described in section 11.1.1. However, there are two additional groups of settings unique to the secondary structure 2D view: **Secondary structure**.

- **Follow structure selection.** This setting pertains to the connection between the structures in the secondary structure table (). If this option is checked, the structure displayed in the secondary structure 2D view will follow the structure selections made in this table. See section 24.2.2 for more information.
- **Layout strategy.** Specify the strategy used for the layout of the structure. In addition to these strategies, you can also modify the layout manually as explained in the next section.
 - **Auto.** The layout is adjusted to minimize overlapping structure elements [Han et al., 1999]. This is the default setting (see figure 24.10).
 - **Proportional.** Arc lengths are proportional to the number of residues (see figure 24.11). Nothing is done to prevent overlap.
 - **Even spread.** Stems are spread evenly around loops as shown in figure 24.12.
- **Reset layout.** If you have manually modified the layout of the structure, clicking this button will reset the structure to the way it was laid out when it was created.

Figure 24.10: *Auto layout. Overlaps are minimized.*

Figure 24.11: *Proportional layout. Length of the arc is proportional to the number of residues in the arc.*

Figure 24.12: *Even spread. Stems are spread evenly around loops.*

Selecting and editing

When you are in **Selection mode** (), you can select parts of the structure like in a normal sequence view:

Press down the mouse button where the selection should start | move the mouse cursor to where the selection should end | release the mouse button

One of the advantages of the secondary structure 2D view is that it is integrated with other views of the same sequence. This means that any selection made in this view will be reflected in other views (see figure 24.13).

Figure 24.13: A split view of the secondary structure view and a linear sequence view.

If you make a selection in another sequence view, this will also be reflected in the secondary structure view.

The *CLC Main Workbench* seeks to produce a layout of the structure where none of the elements overlap. However, it may be desirable to manually edit the layout of a structure for ease of understanding or for the purpose of publication.

To edit a structure, first select the **Pan** (☞) mode in the Tool bar. Now place the mouse cursor on the opening of a stem, and a visual indication of the anchor point for turning the substructure will be shown (see figure 24.14).

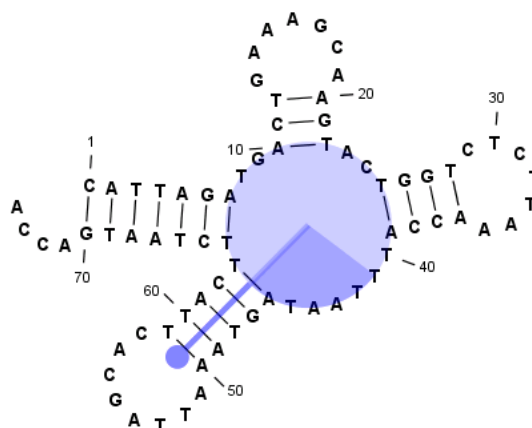

Figure 24.14: The blue circle represents the anchor point for rotating the substructure.

Click and drag to rotate the part of the structure represented by the line going from the anchor point. In order to keep the bases in a relatively sequential arrangement, there is a restriction

on how much the substructure can be rotated. The highlighted part of the circle represents the angle where rotating is allowed.

In figure 24.15, the structure shown in figure 24.14 has been modified by dragging with the mouse.

Figure 24.15: *The structure has now been rotated.*

Press **Reset layout** in the **Side Panel** to reset the layout to the way it looked when the structure was predicted.

24.2.2 Tabular view of structures and energy contributions

There are three main reasons to use the **Secondary structure table**:

- If more than one structure is predicted (see section 24.1), the table provides an overview of all the structures which have been predicted.
- With multiple structures you can use the table to determine which structure should be displayed in the Secondary structure 2D view (see section 24.2.1).
- The table contains a hierarchical display of the elements in the structure with detailed information about each element's energy contribution.

To show the secondary structure table of an already open sequence, click the **Show Secondary Structure Table** (📄) button at the bottom of the sequence view.

If the sequence is not open, click **Show** (📄) and select **Secondary Structure Table** (📄).

This will open a view similar to the one shown in figure 24.16.

On the left side, all computed structures are listed with the information about structure name, when the structure was created, the free energy of the structure and the probability of the structure if the partition function was calculated. Selecting a row (equivalent: a structure) will display a tree of the contained substructures with their contributions to the total structure free energy. Each substructure contains a union of nested structure elements and other substructures (see a detailed description of the different structure elements in section 24.5.2). Each substructure

The screenshot shows a software window titled 'AB009835'. It contains a table with 11 rows of RNA secondary structures. The table has three columns: 'Name', 'Created', and 'ΔG'. The first row is selected. To the right of the table, a list of substructures for the selected structure is displayed, including 'Elements of structure', 'Stem with hairpin at 1..70', and 'Dangling nucleotide at 71'.

Name	Created	ΔG
ΔG = -9,9kcal/mol	2007-06-25 13:3...	-9,9kcal/mol
ΔG = -9,7kcal/mol	2007-06-25 13:3...	-9,7kcal/mol
ΔG = -9,4kcal/mol	2007-06-25 13:3...	-9,4kcal/mol
ΔG = -9,2kcal/mol	2007-06-25 13:3...	-9,2kcal/mol
ΔG = -9,1kcal/mol	2007-06-25 13:3...	-9,1kcal/mol
ΔG = -9,1kcal/mol	2007-06-25 13:3...	-9,1kcal/mol
ΔG = -8,9kcal/mol	2007-06-25 13:3...	-8,9kcal/mol
ΔG = -8,6kcal/mol	2007-06-25 13:3...	-8,6kcal/mol
ΔG = -8,4kcal/mol	2007-06-25 13:3...	-8,4kcal/mol
ΔG = -8,3kcal/mol	2007-06-25 13:3...	-8,3kcal/mol
ΔG = -8,2kcal/mol	2007-06-25 13:3...	-8,2kcal/mol

Elements of structure 'ΔG = -9,9kcal/mol': ΔG = -9,9kcal/mol

- Stem with hairpin at 1..70: ΔG = -8,8kcal/mol
- Dangling nucleotide at 71, dangling from position 70: ΔG =>l

Figure 24.16: The secondary structure table with the list of structures to the left, and to the right the substructures of the selected structure.

contributes a free energy given by the sum of its nested substructure energies and energies of its nested structure elements.

The substructure elements to the right are ordered after their occurrence in the sequence; they are described by a region (the sequence positions covered by this substructure) and an energy contribution. Three examples of mixed substructure elements are "Stem base pairs", "Stem with bifurcation" and "Stem with hairpin".

The "Stem base pairs"-substructure is simply a union of stacking elements. It is given by a joined set of base pair positions and an energy contribution displaying the sum of all stacking element-energies.

The "Stem with bifurcation"-substructure defines a substructure enclosed by a specified base pair with and with energy contribution ΔG . The substructure contains a "Stem base pairs"-substructure and a nested bifurcated substructure (multi loop). Also bulge and interior loops can occur separating stem regions.

The "Stem with hairpin"-substructure defines a substructure starting at a specified base pair with an enclosed substructure-energy given by ΔG . The substructure contains a "Stem base pairs"-substructure and a hairpin loop. Also bulge and interior loops can occur, separating stem regions.

In order to describe the tree ordering of different substructures, we use an example as a starting point (see figure 24.17).

The structure is a (disjoint) nested union of a "Stem with bifurcation"-substructure and a dangling nucleotide. The nested substructure energies add up to the total energy. The "Stem with bifurcation"-substructure is again a (disjoint) union of a "Stem base pairs"-substructure joining position 1-7 with 64-70 and a multi loop structure element opened at base pair(7,64). To see these structure elements, simply expand the "Stem with bifurcation" node (see figure 24.18).

The multi loop structure element is a union of three "Stem with hairpin"-substructures and contributions to the multi loop opening considering multi loop base pairs and multi loop arcs.

Selecting an element in the table to the right will make a corresponding selection in the **Show Secondary Structure 2D View** (🔍) if this is also open and if the "Follow structure selection" has been set in the editors side panel. In figure 24.18 the "Stem with bifurcation" is selected in the

Figure 24.17: A split view showing a structure table to the right and the secondary structure 2D view to the left.

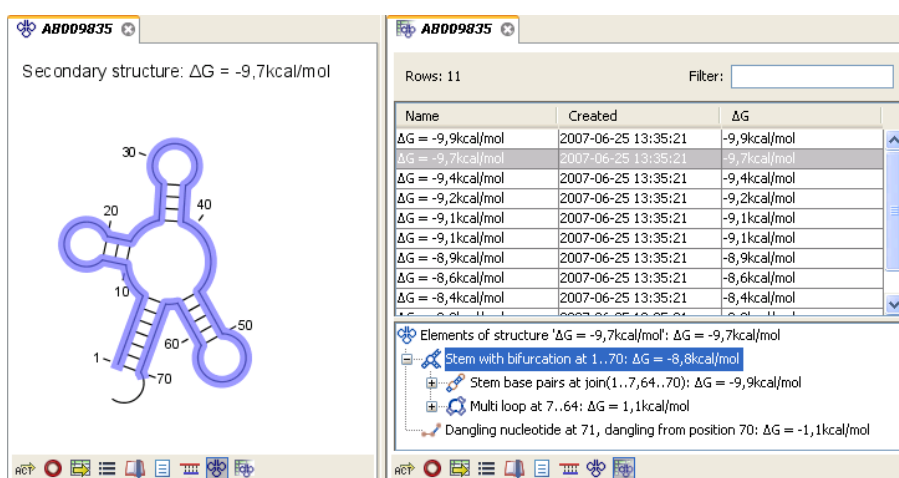

Figure 24.18: Now the "Stem with bifurcation" node has been selected in the table and a corresponding selection has been made in the view of the secondary structure to the left.

table, and this part of the structure is high-lighted in the Secondary Structure 2D view.

The correspondence between the table and the structure editor makes it easy to inspect the thermodynamic details of the structure while keeping a visual overview as shown in the above figures.

Handling multiple structures

The table to the left offers a number of tools for working with structures. Select a structure, right-click, and the following menu items will be available:

- **Open Secondary Structure in 2D View** (🔗). This will open the selected structure in the Secondary structure 2D view.
- **Annotate Sequence with Secondary Structure**. This will add the structure elements as annotations to the sequence. Note that existing structure annotations will be removed.
- **Rename Secondary Structure**. This will allow you to specify a name for the structure to be

displayed in the table.

- **Delete Secondary Structure.** This will delete the selected structure.
- **Delete All Secondary Structures.** This will delete all the selected structures. Note that once you save and close the view, this operation is irreversible. As long as the view is open, you can **Undo** (↶) the operation.

24.2.3 Symbolic representation in sequence view

In the **Side Panel** of normal sequence views (RCP), you will find an extra group under **Nucleotide info** called **Secondary Structure**. This is used to display a symbolic representation of the secondary structure along the sequence (see figure 24.19).

Figure 24.19: The secondary structure visualized below the sequence and with annotations shown above.

The following options can be set:

- **Show all structures.** If more than one structure is predicted, this option can be used if all the structures should be displayed.
- **Show first.** If not all structures are shown, this can be used to determine the number of structures to be shown.
- **Sort by.** When you select to display e.g. four out of eight structures, this option determines which the "first four" should be.
 - Sort by ΔG .
 - Sort by name.
 - Sort by time of creation.

If these three options do not provide enough control, you can rename the structures in a meaningful alphabetical way so that you can use the "name" to display the desired ones.

- **Match symbols.** How a base pair should be represented.
- **No match symbol.** How bases which are not part of a base pair should be represented.

- **Height.** When you zoom out, this option determines the height of the symbols as shown in figure 24.20 (when zoomed in, there is no need for specifying the height).
- **Base pair probability.** See section 24.2.4 below).

When you zoom in and out, the appearance of the symbols change. In figure 24.19, the view is zoomed in. In figure 24.20 you see the same sequence zoomed out to fit the width of the sequence.

Figure 24.20: The secondary structure visualized below the sequence and with annotations shown above. The view is zoomed out to fit the width of the sequence.

24.2.4 Probability-based coloring

In the **Side Panel** of both linear and secondary structure 2D views, you can choose to color structure symbols and sequence residues according to the probability of base pairing / not base pairing, as shown in figure 24.4.

In the linear sequence view (↔), this is found in **Nucleotide info** under **Secondary structure**, and in the secondary structure 2D view (⌘), it is found under **Residue coloring**.

For both paired and unpaired bases, you can set the foreground color and the background color to a gradient with the color at the left side indicating a probability of 0, and the color at the right side indicating a probability of 1.

Note that you have to **Zoom to 100%** (⌘) in order to see the coloring.

24.3 Evaluate structure hypothesis

Hypotheses about an RNA structure can be tested using *CLC Main Workbench*. A structure hypothesis H is formulated using the structural constraint annotations described in section 24.1.4. By adding several annotations complex structural hypotheses can be formulated (see 24.21).

Given the set S of all possible structures, only a subset of these S_H will comply with the formulated hypotheses. We can now find the probability of H as:

$$P(H) = \frac{\sum_{s_H \in S_H} P(s_H)}{\sum_{s \in S} P(s)} = \frac{PF_H}{PF_{\text{full}}},$$

where PF_H is the partition function calculated for all structures permissible by H (S_H) and PF_{full} is the full partition function. Calculating the probability can thus be done with two passes of the partition function calculation, one with structural constraints, and one without. 24.21.

Figure 24.21: Two constraints defining a structural hypothesis.

24.3.1 Selecting sequences for evaluation

The evaluation is started from the **Toolbox**:

Toolbox | RNA Structure (🔍) | Evaluate Structure Hypothesis (🔍?)

This opens the dialog shown in figure 24.22.

Figure 24.22: Selecting RNA or DNA sequences for evaluating structure hypothesis.

If you have selected sequences before choosing the Toolbox action, they are now listed in the **Selected Elements** window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements. Note, that the selected sequences must contain a structure hypothesis in the form of manually added constraint annotations.

Click **Next** to adjust evaluation parameters (see figure 24.23).

The partition function algorithm includes a number of advanced options:

- **Avoid isolated base pairs.** The algorithm filters out isolated base pairs (i.e. stems of length 1).
- **Apply different energy rules for Grossly Asymmetric Interior Loops (GAIL).** Compute the minimum free energy applying different rules for Grossly Asymmetry Interior Loops (GAIL). A Grossly Asymmetry Interior Loop (GAIL) is an interior loop that is $1 \times n$ or $n \times 1$ where $n > 2$ (see <http://www.bioinfo.rpi.edu/~zukerm/lectures/RNAfold-html/rnafold-print.pdf>).
- **Include coaxial stacking energy rules.** Include free energy increments of coaxial stacking for adjacent helices [Mathews et al., 2004].

Figure 24.23: Adjusting parameters for hypothesis evaluation.

24.3.2 Probabilities

After evaluation of the structure hypothesis an annotation is added to the input sequence. This annotation covers the same region as the annotations that constituted the hypothesis and contains information about the probability of the evaluated hypothesis (see figure 24.24).

Figure 24.24: This hypothesis has a probability of 0.338 as shown in the annotation.

24.4 Structure Scanning Plot

In *CLC Main Workbench* it is possible to scan larger sequences for the existence of local conserved RNA structures. The structure scanning approach is similar in spirit to the works of [Workman and Krogh, 1999] and [Clote et al., 2005]. The idea is that if natural selection is operating to maintain a stable local structure in a given region, then the minimum free energy of the region will be markedly lower than the minimum free energy found when the nucleotides of the subsequence are distributed in random order.

The algorithm works by sliding a window along the sequence. Within the window, the minimum free energy of the subsequence is calculated. To evaluate the significance of the local structure signal its minimum free energy is compared to a background distribution of minimum free energies obtained from shuffled sequences, using Z -scores [Rivas and Eddy, 2000]. The Z -score statistics corresponds to the number of standard deviations by which the minimum free energy of the original sequence deviates from the average energy of the shuffled sequences. For a given Z -score, the statistical significance is evaluated as the probability of observing a more extreme Z -score under the assumption that Z -scores are normally distributed [Rivas and Eddy, 2000].

24.4.1 Selecting sequences for scanning

The scanning is started from the **Toolbox**:

Toolbox | RNA Structure (🔍) | Evaluate Structure Hypothesis (📊)

This opens the dialog shown in figure 24.25.

Figure 24.25: Selecting RNA or DNA sequences for structure scanning.

If you have selected sequences before choosing the Toolbox action, they are now listed in the **Selected Elements** window of the dialog. Use the arrows to add or remove sequences or sequence lists from the selected elements.

Click **Next** to adjust scanning parameters (see figure 24.26).

The first group of parameters pertain to the methods of sequence resampling. There are four ways of resampling, all described in detail in [Clote et al., 2005]:

- **Mononucleotide shuffling.** Shuffle method generating a sequence of the exact same mononucleotide frequency

- **Dinucleotide shuffling.** Shuffle method generating a sequence of the exact same dinucleotide frequency
- **Mononucleotide sampling from zero order Markov chain.** Resampling method generating a sequence of the same expected mononucleotide frequency.
- **Dinucleotide sampling from first order Markov chain.** Resampling method generating a sequence of the same expected dinucleotide frequency.

The second group of parameters pertain to the scanning settings and include:

- **Window size.** The width of the sliding window.
- **Number of samples.** The number of times the sequence is resampled to produce the background distribution.
- **Step increment.** Step increment when plotting sequence positions against scoring values.

The third parameter group contains the output options:

- **Z-scores.** Create a plot of Z-scores as a function of sequence position.
- **P-values.** Create a plot of the statistical significance of the structure signal as a function of sequence position.

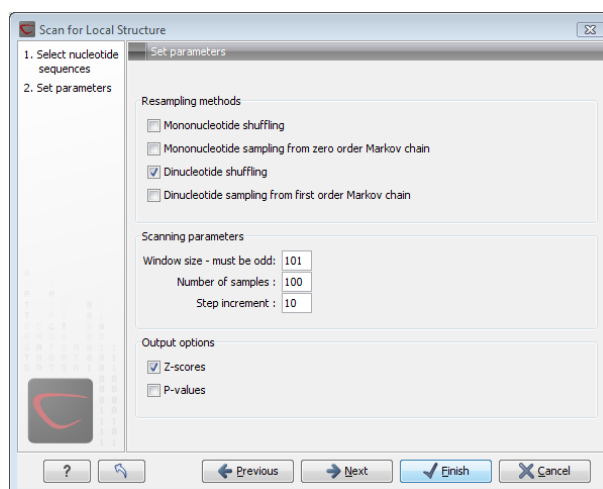

Figure 24.26: Adjusting parameters for structure scanning.

24.4.2 The structure scanning result

The output of the analysis are plots of Z -scores and probabilities as a function of sequence position. A strong propensity for local structure can be seen as spikes in the graphs (see figure 24.27).

Figure 24.27: A plot of the Z-scores produced by sliding a window along a sequence.

24.5 Bioinformatics explained: RNA structure prediction by minimum free energy minimization

RNA molecules are hugely important in the biology of the cell. Besides their rather simple role as an intermediate messenger between DNA and protein, RNA molecules can have a plethora of biologic functions. Well known examples of this are the infrastructural RNAs such as tRNAs, rRNAs and snRNAs, but the existence and functionality of several other groups of non-coding RNAs are currently being discovered. These include micro- (miRNA), small interfering- (siRNA), Piwi interacting- (piRNA) and small modulatory RNAs (smRNA) [Costa, 2007].

A common feature of many of these non-coding RNAs is that the molecular structure is important for the biological function of the molecule.

Ideally, biological function is best interpreted against a 3D structure of an RNA molecule. However, 3D structure determination of RNA molecules is time-consuming, expensive, and difficult [Shapiro et al., 2007] and there is therefore a great disparity between the number of known RNA sequences and the number of known RNA 3D structures.

However, as it is the case for proteins, RNA tertiary structures can be characterized by secondary structural elements. These are defined by hydrogen bonds within the molecule that form several recognizable "domains" of secondary structure like stems, hairpin loops, bulges and internal loops (see below). Furthermore, the high degree of base-pair conservation observed in the evolution of RNA molecules shows that a large part of the functional information is actually contained in the secondary structure of the RNA molecule.

Fortunately, RNA secondary structure can be computationally predicted from sequence data allowing researchers to map sequence information to functional information. The subject of this

paper is to describe a very popular way of doing this, namely free energy minimization. For an in-depth review of algorithmic details, we refer the reader to [Mathews and Turner, 2006].

24.5.1 The algorithm

Consider an RNA molecule and one of its possible structures S_1 . In a stable solution there will be an equilibrium between unstructured RNA strands and RNA strands folded into S_1 . The propensity of a strand to leave a structure such as S_1 (the stability of S_1), is determined by the free energy change involved in its formation. The structure with the lowest free energy (S_{min}) is the most stable and will also be the most represented structure at equilibrium. The objective of minimum free energy (MFE) folding is therefore to identify S_{min} amongst all possible structures.

In the following, we only consider structures without pseudoknots, i.e. structures that do not contain any non-nested base pairs.

Under this assumption, a sequence can be folded into a single coherent structure or several sequential structures that are joined by unstructured regions. Each of these structures is a union of well described structure elements (see below for a description of these). The free energy for a given structure is calculated by an additive nearest neighbor model. Additive, means that the total free energy of a secondary structure is the sum of the free energies of its individual structural elements. Nearest neighbor, means that the free energy of each structure element depends only on the residues it contains and on the most adjacent Watson-Crick base pairs.

The simplest method to identify S_{min} would be to explicitly generate all possible structures, but it can be shown that the number of possible structures for a sequence grows exponentially with the sequence length [Zuker and Sankoff, 1984] leaving this approach unfeasible. Fortunately, a two step algorithm can be constructed which implicitly surveys all possible structures without explicitly generating the structures [Zuker and Stiegler, 1981]: The first step determines the free energy for each possible sequence fragment starting with the shortest fragments. Here, the lowest free energy for longer fragments can be expediently calculated from the free energies of the smaller sub-sequences they contain. When this process reaches the longest fragment, i.e., the complete sequence, the MFE of the entire molecule is known. The second step is called traceback, and uses all the free energies computed in the first step to determine S_{min} - the exact structure associated with the MFE. Acceptable calculation speed is achieved by using *dynamic programming* where sub-sequence results are saved to avoid recalculation. However, this comes at the price of a higher requirement for computer memory.

The structure element energies that are used in the recursions of these two steps, are derived from empirical calorimetric experiments performed on small molecules see e.g. [Mathews et al., 1999].

Suboptimal structures determination

A number of known factors violate the assumptions that are implicit in MFE structure prediction. [Schroeder et al., 1999] and [Chen et al., 2004] have shown experimental indications that the thermodynamic parameters are sequence dependent. Moreover, [Longfellow et al., 1990] and [Kierzek et al., 1999], have demonstrated that some structural elements show non-nearest neighbor effects. Finally, single stranded nucleotides in multi loops are known to influence stability [Mathews and Turner, 2002].

These phenomena can be expected to limit the accuracy of RNA secondary structure prediction

by free energy minimization and it should be clear that the predicted MFE structure may deviate somewhat from the actual preferred structure of the molecule. This means that it may be informative to inspect the landscape of suboptimal structures which surround the MFE structure to look for general structural properties which seem to be robust to minor variations in the total free energy of the structure.

An effective procedure for generating a sample of suboptimal structures is given in [Zuker, 1989a]. This algorithm works by going through all possible Watson-Crick base pair in the molecule. For each of these base pairs, the algorithm computes the most optimal structure among all the structures that contain this pair, see figure 24.28.

Figure 24.28: A number of suboptimal structures have been predicted using **CLC Main Workbench** and are listed at the top left. At the right hand side, the structural components of the selected structure are listed in a hierarchical structure and on the left hand side the structure is displayed.

24.5.2 Structure elements and their energy contribution

In this section, we classify the structure elements defining a secondary structure and describe their energy contribution.

Figure 24.29: The different structure elements of RNA secondary structures predicted with the free energy minimization algorithm in **CLC Main Workbench**. See text for a detailed description.

Nested structure elements

The structure elements involving nested base pairs can be classified by a given base pair and the other base pairs that are nested and *accessible* from this pair. For a more elaborate description we refer the reader to [Sankoff et al., 1983] and [Zuker and Sankoff, 1984].

If the nucleotides with position number (i, j) form a base pair and $i < k, l < j$, then we say that the base pair (k, l) is **accessible** from (i, j) if there is no intermediate base pair (i', j') such that $i < i' < k, l < j' < j$. This means that (k, l) is nested within the pair i, j and there is no other base pair in between.

Using the number of accessible base pairs, we can define the following distinct structure elements:

1. **Hairpin loop** (). A base pair with 0 other accessible base pairs forms a *hairpin loop*. The energy contribution of a hairpin is determined by the length of the unpaired (loop) region and the two bases adjacent to the closing base pair which is termed a terminal mismatch (see figure 24.29A).
2. A base pair with 1 accessible base pair can give rise to three distinct structure elements:
 - **Stacking of base pairs** (). A *stacking* of two consecutive pairs occur if $i' - i = 1 = j - j'$. Only canonical base pairs ($A - U$ or $G - C$ or $G - U$) are allowed (see figure 24.29B). The energy contribution is determined by the type and order of the two base pairs.
 - **Bulge** (). A *bulge loop* occurs if $i' - i > 1$ or $j - j' > 1$, but not both. This means that the two base pairs enclose an unpaired region of length 0 on one side and an unpaired region of length ≥ 1 on the other side (see figure 24.29C). The energy contribution of a bulge is determined by the length of the unpaired (loop) region and the two closing base pairs.
 - **Interior loop** (). An *interior loop* occurs if both $i' - i > 1$ and $i - j' > 1$ This means that the two base pairs enclose an unpaired region of length ≥ 1 on both sides (see figure 24.29D). The energy contribution of an interior loop is determined by the length of the unpaired (loop) region and the four unpaired bases adjacent to the opening- and the closing base pair.
3. **Multi loop opened** (). A base pair with more than two accessible base pairs gives rise to a *multi loop*, a loop from which three or more stems are opened (see figure 24.29E). The energy contribution of a multi loop depends on the number of **Stems opened in multi-loop** () that protrude from the loop.

Other structure elements

- A collection of single stranded bases not accessible from any base pair is called an *exterior (or external) loop* (see figure 24.29F). These regions do not contribute to the total free energy.
- **Dangling nucleotide** (). A *dangling nucleotide* is a single stranded nucleotide that forms a stacking interaction with an adjacent base pair. A dangling nucleotide can be a 3' or 5'-dangling nucleotide depending on the orientation (see figure 24.29G). The energy contribution is determined by the single stranded nucleotide, its orientation and on the adjacent base pair.
- **Non-GC terminating stem** ($A-U$). If a base pair other than a G-C pair is found at the end of a stem, an energy penalty is assigned (see figure 24.29H).
- **Coaxial interaction** (). Coaxial stacking is a favorable interaction of two stems where the base pairs at the ends can form a stacking interaction. This can occur between stems in a multi loop and between the stems of two different sequential structures. Coaxial stacking can occur between stems with no intervening nucleotides (adjacent stems) and between stems with one intervening nucleotide from each strand (see figure 24.29I). The energy contribution is determined by the adjacent base pairs and the intervening nucleotides.

Experimental constraints

A number of techniques are available for probing RNA structures. These techniques can determine individual components of an existing structure such as the existence of a given base pair. It is possible to add such experimental constraints to the secondary structure prediction based on free energy minimization (see figure 24.30) and it has been shown that this can dramatically increase the fidelity of the secondary structure prediction [Mathews and Turner, 2006].

Figure 24.30: Known structural features can be added as constraints to the secondary structure prediction algorithm in **CLC Main Workbench**.

Comparison of workbenches

Below we list a number of functionalities that differ between CLC Workbenches and the CLC Sequence Viewer:

- CLC Sequence Viewer (■)
- CLC Main Workbench (■)
- CLC Genomics Workbench (■)

Data handling	Viewer	Main	Genomics
Add multiple locations to Navigation Area		■	■
Share data on network drive		■	■
Search all your data		■	■
Assembly of sequencing data	Viewer	Main	Genomics
Advanced contig assembly		■	■
Importing and viewing trace data		■	■
Trim sequences		■	■
Assemble without use of reference sequence		■	■
Map to reference sequence		■	■
Assemble to existing contig		■	■
Viewing and edit contigs		■	■
Tabular view of an assembled contig (easy data overview)		■	■
Secondary peak calling		■	■
Multiplexing based on barcode or name		■	■

Next-generation Sequencing Data Analysis	Viewer	Main	Genomics
Import of 454, Illumina Genome Analyzer, SOLiD and Helicos data			■
Reference assembly of human-size genomes			■
De novo assembly			■
SNP/DIP detection			■
Graphical display of large contigs			■
Support for mixed-data assembly			■
Paired data support			■
RNA-Seq analysis			■
Expression profiling by tags			■
ChIP-Seq analysis			■
Expression Analysis	Viewer	Main	Genomics
Import of Illumina BeadChip, Affymetrix, GEO data		■	■
Import of Gene Ontology annotation files		■	■
Import of Custom expression data table and Custom annotation files		■	■
Multigroup comparisons		■	■
Advanced plots: scatter plot, volcano plot, box plot and MA plot		■	■
Hierarchical clustering		■	■
Statistical analysis on count-based and gaussian data		■	■
Annotation tests		■	■
Principal component analysis (PCA)		■	■
Hierarchical clustering and heat maps		■	■
Analysis of RNA-Seq/Tag profiling samples		■	■
Molecular cloning	Viewer	Main	Genomics
Advanced molecular cloning		■	■
Graphical display of in silico cloning		■	■
Advanced sequence manipulation		■	■
Database searches	Viewer	Main	Genomics
GenBank Entrez searches	■	■	■
UniProt searches (Swiss-Prot/TrEMBL)		■	■
Web-based sequence search using BLAST		■	■
BLAST on local database		■	■
Creation of local BLAST database		■	■
PubMed lookup		■	■
Web-based lookup of sequence data		■	■
Search for structures (at NCBI)		■	■

General sequence analyses	Viewer	Main	Genomics
Linear sequence view	■	■	■
Circular sequence view	■	■	■
Text based sequence view		■	■
Editing sequences	■	■	■
Adding and editing sequence annotations		■	■
Advanced annotation table		■	■
Join multiple sequences into one	■	■	■
Sequence statistics	■	■	■
Shuffle sequence	■	■	■
Local complexity region analyses		■	■
Advanced protein statistics		■	■
Comprehensive protein characteristics report		■	■
Nucleotide analyses	Viewer	Main	Genomics
Basic gene finding	■	■	■
Reverse complement without loss of annotation	■	■	■
Restriction site analysis	■	■	■
Advanced interactive restriction site analysis		■	■
Translation of sequences from DNA to proteins	■	■	■
Interactive translations of sequences and alignments		■	■
G/C content analyses and graphs		■	■
Protein analyses	Viewer	Main	Genomics
3D molecule view		■	■
Hydrophobicity analyses		■	■
Antigenicity analysis		■	■
Protein charge analysis		■	■
Reverse translation from protein to DNA		■	■
Proteolytic cleavage detection		■	■
Prediction of signal peptides (SignalP)		■	■
Transmembrane helix prediction (TMHMM)		■	■
Secondary protein structure prediction		■	■
PFAM domain search		■	■

Sequence alignment	Viewer	Main	Genomics
Multiple sequence alignments (Two algorithms)	■	■	■
Advanced re-alignment and fix-point alignment options		■	■
Advanced alignment editing options	■	■	■
Join multiple alignments into one		■	■
Consensus sequence determination and management	■	■	■
Conservation score along sequences	■	■	■
Sequence logo graphs along alignments		■	■

Appendix B

Graph preferences

This section explains the view settings of graphs. The **Graph preferences** at the top of the **Side Panel** includes the following settings:

- **Lock axes.** This will always show the axes even though the plot is zoomed to a detailed level.
- **Frame.** Shows a frame around the graph.
- **Show legends.** Shows the data legends.
- **Tick type.** Determine whether tick lines should be shown outside or inside the frame.
 - Outside
 - Inside
- **Tick lines at.** Choosing Major ticks will show a grid behind the graph.
 - None
 - Major ticks
- **Horizontal axis range.** Sets the range of the horizontal axis (x axis). Enter a value in **Min** and **Max**, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.
- **Vertical axis range.** Sets the range of the vertical axis (y axis). Enter a value in **Min** and **Max**, and press Enter. This will update the view. If you wait a few seconds without pressing Enter, the view will also be updated.
- **X-axis at zero.** This will draw the x axis at $y = 0$. Note that the axis range will not be changed.
- **Y-axis at zero.** This will draw the y axis at $x = 0$. Note that the axis range will not be changed.
- **Show as histogram.** For some data-series it is possible to see the graph as a histogram rather than a line plot.

The **Lines and plots** below contains the following settings:

- **Dot type**

- None
- Cross
- Plus
- Square
- Diamond
- Circle
- Triangle
- Reverse triangle
- Dot

- **Dot color.** Allows you to choose between many different colors. Click the color box to select a color.

- **Line width**

- Thin
- Medium
- Wide

- **Line type**

- None
- Line
- Long dash
- Short dash

- **Line color.** Allows you to choose between many different colors. Click the color box to select a color.

For graphs with multiple data series, you can select which curve the dot and line preferences should apply to. This setting is at the top of the **Side Panel** group.

Note that the graph title and the axes titles can be edited simply by clicking with the mouse. These changes will be saved when you **Save**  the graph - whereas the changes in the **Side Panel** need to be saved explicitly (see section 5.6).

For more information about the graph view, please see section B.

Appendix C

Working with tables

Tables are used in a lot of places in the *CLC Main Workbench*. The contents of the tables are of course different depending on the context, but there are some general features for all tables that will be explained in the following.

Figure C.1 shows an example of a typical table. This is the table result of **Find Open Reading Frames** (✂). We will use this table as an example in the following to illustrate the concepts that are relevant for all kinds of tables.

The screenshot shows a window titled "Find reading ..." with a table of results. The table has 5 columns: Start, End, Length, Found at strand, and Start codon. The "Table Settings" panel on the right shows options for column width (Automatic) and column visibility (all checked). Buttons for "Select All" and "Deselect All" are also present.

Start	End	Length	Found at strand	Start codon
1	348	348	positive	ACT
14	586	573	negative	NNN
405	800	396	negative	GTT
433	789	357	positive	TGC
462	767	306	positive	ACC
1378	1752	375	negative	TAT
1998	2309	312	negative	AAT
3462	3887	426	negative	CAC
3779	4174	396	positive	AGG
4970	5323	354	positive	AGG
7214	7582	369	positive	TTG
11369	11674	306	negative	AGA
15209	15559	351	negative	CTC
18424	18747	324	positive	AGG
18435	18737	303	negative	GTG

Figure C.1: A table showing open reading frames.

First of all, the columns of the table are listed in the **Side Panel** to the right of the table. By clicking the checkboxes you can hide/show the columns in the table.

Furthermore, you can **sort** the table by clicking on the column headers. (Pressing Ctrl - ⌘ on Mac - while you click will refine the existing sorting).

C.1 Filtering tables

The final concept to introduce is **Filtering**. The table filter has an advanced and a simple mode. The simple mode is the default and is applied simply by typing text or numbers (see an example in figure C.2).

Rows: 91 / 169 Find reading frame output Filter:

Start	End	Length	Found at strand	Start codon
14	586	573	negative	NNN
405	800	396	negative	GTT
1378	1752	375	negative	TAT
1998	2309	312	negative	AAT
3462	3887	426	negative	CAC

Figure C.2: Typing "neg" in the filter in simple mode.

Typing "neg" in the filter will only show the rows where "neg" is part of the text in any of the columns (also the ones that are not shown). The text does not have to be in the beginning, thus "ega" would give the same result. This simple filter works fine for fast, textual and non-complicated filtering and searching.

However, if you wish to make use of numerical information or make more complex filters, you can switch to the advanced mode by clicking the **Advanced filter** (⚙️) button. The advanced filter is structured in a different way: First of all, you can have more than one criterion in the filter. Criteria can be added or removed by clicking the **Add** (+) or **Remove** (✖️) buttons. At the top, you can choose whether all the criteria should be fulfilled (**Match all**), or if just one of the needs to be fulfilled (**Match any**).

For each filter criterion, you first have to select which column it should apply to. Next, you choose an operator. For numbers, you can choose between:

- = (equal to)
- < (smaller than)
- > (greater than)
- <> (not equal to)
- **abs. value** < (absolute value smaller than. This is useful if it doesn't matter whether the number is negative or positive)
- **abs. value** > (absolute value greater than. This is useful if it doesn't matter whether the number is negative or positive)

For text-based columns, you can choose between:

- **contains** (the text does not have to be in the beginning)
- **doesn't contain**

- = (the whole text in the table cell has to match, also lower/upper case)

Once you have chosen an operator, you can enter the text or numerical value to use.

If you wish to reset the filter, simply remove (✖) all the search criteria. Note that the last one will not disappear - it will be reset and allow you to start over.

Figure C.3 shows an example of an advanced filter which displays the open reading frames larger than 400 that are placed on the negative strand.

Find reading ...

Rows: 15 / 169 Find reading frame output Filter: Match any Match all

Length > 400

Found at str... contains negative

Apply

Start	End	Length	Found at strand	Start codon
14	586	573	negative	NNN
3462	3887	426	negative	CAC
54714	56564	1851	negative	CAC
54842	56524	1683	negative	ATA
54886	56520	1635	negative	TCT

Figure C.3: The advanced filter showing open reading frames larger than 400 that are placed on the negative strand.

Both for the simple and the advanced filter, there is a counter at the upper left corner which tells you the number of rows that pass the filter (91 in figure C.2 and 15 in figure C.3).

Appendix D

BLAST databases

Several databases are available at NCBI, which can be selected to narrow down the possible BLAST hits.

D.1 Peptide sequence databases

- **nr.** Non-redundant GenBank CDS translations + PDB + SwissProt + PIR + PRF, excluding those in env_nr.
- **refseq.** Protein sequences from NCBI Reference Sequence project <http://www.ncbi.nlm.nih.gov/RefSeq/>.
- **swissprot.** Last major release of the SWISS-PROT protein sequence database (no incremental updates).
- **pat.** Proteins from the Patent division of GenBank.
- **pdb.** Sequences derived from the 3-dimensional structure records from the Protein Data Bank <http://www.rcsb.org/pdb/>.
- **env_nr.** Non-redundant CDS translations from env_nt entries.
- **month.** All new or revised GenBank CDS translations + PDB + SwissProt + PIR + PRF released in the last 30 days..

D.2 Nucleotide sequence databases

- **nr.** All GenBank + EMBL + DDBJ + PDB sequences (but no EST, STS, GSS, or phase 0, 1 or 2 HTGS sequences). No longer "non-redundant" due to computational cost.
- **refseq_rna.** mRNA sequences from NCBI Reference Sequence Project.
- **refseq_genomic.** Genomic sequences from NCBI Reference Sequence Project.
- **est.** Database of GenBank + EMBL + DDBJ sequences from EST division.
- **est_human.** Human subset of est.

- **est_mouse.** Mouse subset of est.
- **est_others.** Subset of est other than human or mouse.
- **gss.** Genome Survey Sequence, includes single-pass genomic data, exon-trapped sequences, and Alu PCR sequences.
- **htgs.** Unfinished High Throughput Genomic Sequences: phases 0, 1 and 2. Finished, phase 3 HTG sequences are in nr.
- **pat.** Nucleotides from the Patent division of GenBank.
- **pdb.** Sequences derived from the 3-dimensional structure records from Protein Data Bank. They are NOT the coding sequences for the corresponding proteins found in the same PDB record.
- **month.** All new or revised GenBank+EMBL+DDBJ+PDB sequences released in the last 30 days.
- **alu.** Select Alu repeats from REPBASE, suitable for masking Alu repeats from query sequences. See "Alu alert" by Claverie and Makalowski, Nature 371: 752 (1994).
- **dbsts.** Database of Sequence Tag Site entries from the STS division of GenBank + EMBL + DDBJ.
- **chromosome.** Complete genomes and complete chromosomes from the NCBI Reference Sequence project. It overlaps with refseq_genomic.
- **wgs.** Assemblies of Whole Genome Shotgun sequences.
- **env_nt.** Sequences from environmental samples, such as uncultured bacterial samples isolated from soil or marine samples. The largest single source is Sagarso Sea project. This does overlap with nucleotide nr.

D.3 Adding more databases

Besides the databases that are part of the default configuration, you can add more databases located at NCBI by configuring files in the Workbench installation directory.

The list of databases that can be added is here: http://www.ncbi.nlm.nih.gov/staff/tao/URLAPI/remote_blastdblist.html.

In order to add a new database, find the `settings` folder in the Workbench installation directory (e.g. `C:\Program files\CLC Genomics Workbench 4`). Download unzip and place the following files in this directory to replace the built-in list of databases:

- Nucleotide databases: http://www.clcbio.com/wbsettings/NCBI_BlastNucleotideDatabases.zip
- Protein databases: http://www.clcbio.com/wbsettings/NCBI_BlastProteinDatabases.zip

Open the file you have downloaded into the `settings` folder, e.g. `NCBI_BlastProteinDatabases.proper` in a text editor and you will see the contents look like this:

```
nr[clcddefault] = Non-redundant protein sequences
refseq_protein = Reference proteins
swissprot = Swiss-Prot protein sequences
pat = Patented protein sequences
pdb = Protein Data Bank proteins
env_nr = Environmental samples
month = New or revised GenBank sequences
```

Simply add another database as a new line with the first item being the database name taken from http://www.ncbi.nlm.nih.gov/staff/tao/URLAPI/remote_blastdblist.html and the second part is the name to display in the Workbench. Restart the Workbench, and the new database will be visible in the BLAST dialog.

Appendix E

Proteolytic cleavage enzymes

Most proteolytic enzymes cleave at distinct patterns. Below is a compiled list of proteolytic enzymes used in *CLC Main Workbench*.

Name	P4	P3	P2	P1	P1'	P2'
Cyanogen bromide (CNBr)	-	-	-	M	-	-
Asp-N endopeptidase	-	-	-	-	D	-
Arg-C	-	-	-	R	-	-
Lys-C	-	-	-	K	-	-
Trypsin	-	-	-	K, R	not P	-
Trypsin	-	-	W	K	P	-
Trypsin	-	-	M	R	P	-
Trypsin*	-	-	C, D	K	D	-
Trypsin*	-	-	C	K	H, Y	-
Trypsin*	-	-	C	R	K	-
Trypsin*	-	-	R	R	H,R	-
Chymotrypsin-high spec.	-	-	-	F, Y	not P	-
Chymotrypsin-high spec.	-	-	-	W	not M, P	-
Chymotrypsin-low spec.	-	-	-	F, L, Y	not P	-
Chymotrypsin-low spec.	-	-	-	W	not M, P	-
Chymotrypsin-low spec.	-	-	-	M	not P, Y	-
Chymotrypsin-low spec.	-	-	-	H	not D, M, P, W	-
o-Iodosobenzoate	-	-	-	W	-	-
Thermolysin	-	-	-	not D, E	A, F, I, L, M or V	-
Post-Pro	-	-	H, K, R	P	not P	-
Glu-C	-	-	-	E	-	-
Asp-N	-	-	-	-	D	-
Proteinase K	-	-	-	A, E, F, I, L, T, V, W, Y	-	-
Factor Xa	A, F, G, I, L, T, V, M	D,E	G	R	-	-
Granzyme B	I	E	P	D	-	-
Thrombin	-	-	G	R	G	-
Thrombin	A, F, G, I, L, T, V, M	A, F, G, I, L, T, V, W, A	P	R	not D, E	not D, E
TEV (Tobacco Etch Virus)	-	Y	-	Q	G, S	-

Appendix F

Restriction enzymes database configuration

CLC Main Workbench uses enzymes from the **REBASE** restriction enzyme database at <http://rebase.neb.com>. If you wish to add enzymes to this list, you can do this by manually using the procedure described here.

Note! Please be aware that this process needs to be handled carefully, otherwise you may have to re-install the Workbench to get it to work.

First, download the following file: http://www.clcbio.com/wbsettings/link_emboss_e_custom. In the Workbench installation folder under `settings`, create a folder named `rebase` and place the extracted `link_emboss_e_custom` file here.

Open the file in a text editor. The top of the file contains information about the format, and at the bottom there are two example enzymes that you should replace with your own.

Please note that the CLC Workbenches only support the addition of 2-cutter enzymes. Further details about how to format your entries accordingly are given within the file mentioned above.

After adding the above file, or making changes to it, you must restart the Workbench for changes take effect.

Appendix G

Technical information about modifying Gateway cloning sites

The *CLC Main Workbench* comes with a pre-defined list of Gateway recombination sites. These sites and the recombination logics can be modified by downloading and editing a properties file. Note that this is a technical procedure only needed if the built-in functionality is not sufficient for your needs.

The properties file can be downloaded from <http://www.clcbio.com/wbsettings/gatewaycloning.zip>. Extract the file included in the zip archive and save it in the `settings` folder of the Workbench installation folder. The file you download contains the standard configuration. You should thus update the file to match your specific needs. See the comments in the file for more information.

The name of the properties file you download is `gatewaycloning.1.properties`. You can add several files with different configurations by giving them a different number, e.g. `gatewaycloning.2.properties` and so forth. When using the Gateway tools in the Workbench, you will be asked which configuration you want to use (see figure [G.1](#)).

Figure G.1: Selecting between different gateway cloning configurations.

Appendix H

IUPAC codes for amino acids

(Single-letter codes based on International Union of Pure and Applied Chemistry)

The information is gathered from: <http://www.ebi.ac.uk/2can/tutorials/aa.html>

One-letter abbreviation	Three-letter abbreviation	Description
A	Ala	Alanine
R	Arg	Arginine
N	Asn	Asparagine
D	Asp	Aspartic acid
C	Cys	Cysteine
Q	Gln	Glutamine
E	Glu	Glutamic acid
G	Gly	Glycine
H	His	Histidine
J	Xle	Leucine or Isoleucine
L	Leu	Leucine
I	Ile	Isoleucine
K	Lys	Lysine
M	Met	Methionine
F	Phe	Phenylalanine
P	Pro	Proline
O	Pyl	Pyrrolysine
U	Sec	Selenocysteine
S	Ser	Serine
T	Thr	Threonine
W	Trp	Tryptophan
Y	Tyr	Tyrosine
V	Val	Valine
B	Asx	Aspartic acid or Asparagine
Z	Glx	Glutamic acid or Glutamine
X	Xaa	Any amino acid

Appendix I

IUPAC codes for nucleotides

(Single-letter codes based on International Union of Pure and Applied Chemistry)

The information is gathered from: <http://www.iupac.org> and <http://www.ebi.ac.uk/2can/tutorials/aa.html>.

Code	Description
A	Adenine
C	Cytosine
G	Guanine
T	Thymine
U	Uracil
R	Purine (A or G)
Y	Pyrimidine (C, T, or U)
M	C or A
K	T, U, or G
W	T, U, or A
S	C or G
B	C, T, U, or G (not A)
D	A, T, U, or G (not C)
H	A, T, U, or C (not G)
V	A, C, or G (not T, not U)
N	Any base (A, C, G, T, or U)

Appendix J

Formats for import and export

J.1 List of bioinformatic data formats

Below is a list of bioinformatic data formats, i.e. formats for importing and exporting sequences, alignments and trees.

J.1.1 Sequence data formats

File type	Suffix	Import	Export	Description
AB1	.ab1	X		Including chromatograms
ABI	.abi	X		Including chromatograms
CLC	.clc	X	X	Rich format including all information
Clone Manager	.cm5	X		
CSV export	.csv		X	Annotations in csv format
DNAstrider	.str/.strider	X	X	
DS Gene	.bsml	X		
Embl	.embl	X	X	Rich information incl. annotations (nucs only)
FASTA	.fsa/.fasta	X	X	Simple format, name & description
GCG sequence	.gcg	X		Rich information incl. annotations
GenBank	.gbk/.gb/.gp	X	X	Rich information incl. annotations
Gene Construction Kit	.gck	X		
Lasergene	.pro/.seq	X		
Nexus	.nxs/.nexus	X	X	
Phred	.phd	X		Including chromatograms
PIR (NBRF)	.pir	X		Simple format, name & description
Raw sequence	any	X		Only sequence (no name)
SCF2	.scf	X		Including chromatograms
SCF3	.scf	X	X	Including chromatograms
Sequence Comma separated values	.csv	X	X	Simple format. One seq per line: name, description(optional), sequence
Staden	.sdn	X		
Swiss-Prot	.swp	X	X	Rich information incl. annotations (only peptides)
Tab delimited text	.txt		X	Annotations in tab delimited text format
Vector NTI archives	.ma4/.pa4/.oa4	X		Archives in rich format
Vector NTI Database		X		Special import full database
Zip export	.zip		X	Selected files in CLC format
Zip import	.zip/.gzip/.tar	X		Contained files/folder structure

J.1.2 Contig formats

File type	Suffix	Import	Export	Description
ACE	.ace	X	X	No chromatogram or quality score
CLC	.clc	X	X	Rich format including all information
Zip export	.zip		X	Selected files in CLC format
Zip import	.zip/.gzip/.tar	X		Contained files/folder structure

J.1.3 Alignment formats

File type	Suffix	Import	Export	Description
Aligned fasta	.fa	X	X	Simple fasta-based format with – for gaps
CLC	.clc	X	X	Rich format including all information
Clustal Alignment	.aln	X	X	
GCG Alignment	.msf	X	X	
Nexus	.nxs/.nexus	X	X	
Phylip Alignment	.phy	X	X	
Zip export	.zip		X	Selected files in CLC format
Zip import	.zip/.gzip/.tar	X		Contained files/folder structure

J.1.4 Tree formats

File type	Suffix	Import	Export	Description
CLC	.clc	X	X	Rich format including all information
Newick	.nwk	X	X	
Nexus	.nxs/.nexus	X	X	
Zip export	.zip		X	Selected files in CLC format
Zip import	.zip/.gzip/.tar	X		Contained files/folder structure

J.1.5 Expression data formats

Read about technical details of these data formats in section [K](#).

File type	Suffix	Import	Export	Description
Affymetrix CHP	.chp/.psi	X		Expression values and annotations
Affymetrix pivot/metric	.txt/.csv	X		Gene-level expression values
Affymetrix NetAffx	.csv	X		Annotations
CLC	.clc	X	X	Rich format including all information
CSV	.csv		X	Samples and experiments,
Excel	.xls/.xlsx		X	All tables and reports
Generic	.txt/.csv	X		expression values
Generic	.txt/.csv	X		annotations
GEO soft sample/series	.txt/.csv	X		Expression values
Illumina	.txt	X		Expression values and annotations
Tab delimited	.txt		X	Samples and experiments,
Zip export	.zip		X	Selected files in CLC format
Zip import	.zip/.gzip/.tar	X		Contained files/folder structure

J.1.6 Miscellaneous formats

File type	Suffix	Import	Export	Description
BLAST Database	.phr/.nhr	X		Link to database imported
CLC	.clc	X	X	Rich format including all information
CSV	.csv		X	All tables
Excel	.xls/.xlsx		X	All tables and reports
GFF	.gff	X	X	See http://www.clcbio.com/clc-plugin/annotate-sequence-with-gff-file/
mmCIF	.cif	X		3D structure
PDB	.pdb	X		3D structure
RNA structures	.ct, .col, .rnaml/.xml	x		Secondary structure for RNA
Tab delimited	.txt		X	All tables
Text	.txt	X	X	All data in a textual format
Zip export	.zip		X	Selected files in CLC format
Zip import	.zip/.gzip/.tar	X		Contained files/folder structure (.tar and .zip not supported for NGS data)

Note! The Workbench can import 'external' files, too. This means that all kinds of files can be imported and displayed in the **Navigation Area**, but the above mentioned formats are the only

ones whose *contents* can be shown in the Workbench.

J.2 List of graphics data formats

Below is a list of formats for exporting graphics. All data displayed in a graphical format can be exported using these formats. Data represented in lists and tables can only be exported in .pdf format (see section 7.3 for further details).

Format	Suffix	Type
Portable Network Graphics	.png	bitmap
JPEG	.jpg	bitmap
Tagged Image File	.tif	bitmap
PostScript	.ps	vector graphics
Encapsulated PostScript	.eps	vector graphics
Portable Document Format	.pdf	vector graphics
Scalable Vector Graphics	.svg	vector graphics

Appendix K

Microarray data formats

Below you find descriptions of the microarray data formats that are supported by *CLC Main Workbench*. Note that we for some platforms support both expression data and annotation data.

K.1 GEO (Gene Expression Omnibus)

The GEO (Gene Expression Omnibus) sample and series formats are supported. Figure K.1 shows how to download the data from GEO in the right format. GEO is located at <http://www.ncbi.nlm.nih.gov/geo/>.

Figure K.1: *Selecting Samples, SOFT and Data before clicking go will give you the format supported by the CLC Main Workbench.*

The GEO sample files are tab-delimited .txt files. They have three required lines:

```
^SAMPLE = GSM21610
!sample_table_begin
...
!sample_table_end
```

The first line should start with ^SAMPLE = followed by the sample name, the line !sample_table_begin and the line !sample_table_end. Between the !sample_table_begin and !sample_table_end, lines are the column contents of the sample.

Note that GEO sample importer will also work for concatenated GEO sample files – allowing multiple samples to be imported in one go. Download a sample file containing concatenated sample files here:

<http://www.clcbio.com/madata/GEOSampleFilesConcatenated.txt>

Below you can find examples of the formatting of the GEO formats.

K.1.1 GEO sample file, simple

This format is very simple and includes two columns: one for feature id (e.g. gene name) and one for the expression value.

```
^SAMPLE = GSM21610
!sample_table_begin
ID_REF    VALUE
id1       105.8
id2       32
id3       50.4
id4       57.8
id5       2914.1
!sample_table_end
```

Download the sample file here:

<http://www.clcbio.com/madata/GEOSampleFileSimple.txt>

K.1.2 GEO sample file, including present/absent calls

This format includes an extra column for absent/present calls that can also be imported.

```
^SAMPLE = GSM21610
!sample_table_begin
ID_REF    VALUE    ABS_CALL
id1       105.8    M
id2       32       A
id3       50.4    A
id4       57.8    A
id5       2914.1  P
!sample_table_end
```

Download the sample file here:

<http://www.clcbio.com/madata/GEOSampleFileAbsentPresent.txt>

K.1.3 GEO sample file, including present/absent calls and p-values

This format includes two extra columns: one for absent/present calls and one for absent/present call p-values, that can also be imported.

```
^SAMPLE = GSM21610
```

```
!sample_table_begin
ID_REF      VALUE      ABS_CALL      DETECTION P-VALUE
id1         105.8      M              0.00227496
id2         32         A              0.354441
id3         50.4      A              0.904352
id4         57.8      A              0.937071
id5         2914.1    P              6.02111e-05
!sample_table_end
```

Download the sample file here:

<http://www.clcbio.com/madata/GEOSampleFileAbsentPresentCallAndPValue.txt>

K.1.4 GEO sample file: using absent/present call and p-value columns for sequence information

The workbench assumes that if there is a third column in the GEO sample file then it contains present/absent calls and that if there is a fourth column then it contains p-values for these calls. This means that the contents of the third column is assumed to be text and that of the fourth column a number. As long as these two basic requirements are met, the sample should be recognized and interpreted correctly.

You can thus use these two columns to carry additional information on your probes. The absent/present column can be used to carry additional information like e.g. sequence tags as shown below:

```
^SAMPLE = GSM21610
!sample_table_begin
ID_REF      VALUE      ABS_CALL
id1         105.8      AAA
id2         32         AAC
id3         50.4      ATA
id4         57.8      ATT
id5         2914.1    TTA
!sample_table_end
```

Download the sample file here:

<http://www.clcbio.com/madata/GEOSampleFileSimpleSequenceTag.txt>

Or, if you have multiple probes per sequence you could use the present/absent column to hold the sequence name and the p-value column to hold the interrogation position of your probes:

```
^SAMPLE = GSM21610
!sample_table_begin
ID_REF      VALUE      ABS_CALL      DETECTION P-VALUE
probe1      755.07    seq1          1452
probe2      587.88    seq1          497
probe3      716.29    seq1          1447
probe4      1287.18   seq2          1899
!sample_table_end
```

Download the sample file here:

<http://www.clcbio.com/madata/GEOSampleFileSimpleSequenceTagAndProbe.txt>

K.1.5 GEO series file, simple

The series file includes expression values for multiple samples. Each of the samples in the file will be represented by its own element with the sample name. The first row lists the sample names.

```
!Series_title "Myb specificity determinants"
!series_matrix_table_begin
"ID_REF" "GSM21610" "GSM21611" "GSM21612"
"id1"      2541      1781.8      1804.8
"id2"      11.3      621.5      50.2
"id3"      61.2      149.1      22
"id4"      55.3      328.8      97.2
"id5"      183.8      378.3      423.2
!series_matrix_table_end
```

Download the sample file here:

<http://www.clcbio.com/madata/GEOSeriesFile.txt>

K.2 Affymetrix GeneChip

For Affymetrix, three types of files are currently supported: Affymetrix .CHP files, Affymetrix NetAffx annotation files and tab-delimited pivot or metrics files. Affymetrix .CEL files are currently not supported. However, the Bioconductor R package 'affy' allows you to preprocess the .CEL files and export a txt file containing a table of estimated gene-level expression values in three lines of code:

```
library(affy) # loading Bioconductor library 'affy'
data=ReadAffy() # probe-level data import
eset=rma(data) # probe-level data pre-processing using 'rma'
write.exprs(eset,file="evals.txt") # writing gene expression levels to 'evals-txt'
```

The exported txt file (evals.txt) can be imported into the workbench using the Generic expression data table format importer (see section K.5; you can just 'drag-and-drop' it in). In R, you should have all the CEL files you wish to process in your working directory and the file 'evals.txt' will be written to that directory.

K.2.1 Affymetrix CHP expression files

The Affymetrix scanner software produces a number of files when a GeneChip is scanned. Two of these are the .CHP and the .CEL files. These are binary files with native Affymetrix formats. The Affymetrix GeneChips contain a number of probes for each gene (typically between 22 and 40). The .CEL file contains the probe-level intensities, and the .CHP file contains the gene-level information. The gene-level information has been obtained by the scanner software through postprocessing and summarization of the probe-level intensities.

In order to interpret the probe-level information in the .CEL file, the .CDF file for the type of GeneChip that was used is required. Similarly for the .CHP file: in order to interpret the gene-level information in the .CHP file, the .PSI file for the type of GeneChip that was used is required.

In order to import a .CHP file it is required that the corresponding .PSI file is present in the same folder as the .CHP file you want to import, and furthermore, this must be the only .PSI file that is present there. There are no requirements for the name of the .PSI file. Note that the .PSI file itself will not be imported - it is only used to guide the import of the .CHP file which contains the expression values.

Download example .CHP and .PSI files here (note that these are binary files):

<http://www.clcbio.com/madata/AffymetrixCHPandPSI.zip>

K.2.2 Affymetrix metrics files

The Affymetrix metrics or pivot files are tab-delimited files that may be exported from the Affymetrix scanner software. The metrics files have a lot of technical information that is only partly used in the Workbench. The feature ids (Probe Set Name), expression values (Used Signal), absent/present call (Detection) and absent/present p-value (Detection p-value) are imported into the Workbench.

Download a small example sample file here:

<http://www.clcbio.com/madata/AffymetrixMetrics.txt>

K.2.3 Affymetrix NetAffx annotation files

The NetAffx annotation files for Whole-Transcript Expression Gene arrays and 3' IVT Expression Analysis Arrays can be imported and used to annotate experiments as shown in section 20.1.4.

Download a small example annotation file here which includes header information:

<http://www.clcbio.com/madata/AffymetrixNetAffxAnnotationFile.csv>

K.3 Illumina BeadChip

Both BeadChip expression data files from Illumina's BeadStudio software and the corresponding BeadChip annotation files are supported by *CLC Main Workbench*. The formats of the BeadStudio and annotation files have changed somewhat over time and various formats are supported.

K.3.1 Illumina expression data, compact format

An example of this format is shown below:

TargetID	AVG_Signal	BEAD_STDEV	Detection
GI_10047089-S	112.5	4.2	0.16903226
GI_10047091-S	127.6	4.8	0.76774194

All this information is imported into the Workbench. The `AVG_Signal` is used as the expression measure.

Download a small sample file here:

<http://www.clcbio.com/madata/IlluminaBeadChipCompact.txt>

K.3.2 Illumina expression data, extended format

An example of this format is shown below:

TargetID	MIN_Signal	AVG_Signal	MAX_Signal	NARRAYS	ARRAY_STDEV	BEAD_STDEV	Avg_NBBEADS	Detection
GI_10047089-S	73.7	73.7	73.7	1	NaN	3.4	53	0.05669084
GI_10047091-S	312.7	312.7	312.7	1	NaN	11.1	50	0.99604483

All this information is imported into the Workbench. The AVG_Signal is used as the expression measure.

Download a small sample file here:

<http://www.clcbio.com/madata/IlluminaBeadChipExtended.txt>

K.3.3 Illumina expression data, with annotations

An example of this format is shown below:

TargetID	Accession	Symbol	Definition	Synonym	Signal-BG02	DCp32	Detection-BG02	DCp32
GI_10047089-S	NM_014332.1	SMPX	"Homo sapiens small muscle protein, X-linked (SMPX), mRNA."		-17.6		0.03559657	
GI_10047091-S	NM_013259.1	NP25	"Homo sapiens neuronal protein (NP25), mRNA."		NP22	32.6	0.99604483	
GI_10047093-S	NM_016299.1	HSP70-4	"Homo sapiens likely ortholog of mouse heat shock protein, 70 kDa 4 (HSP70-4), mRNA."		228.1	1		

Only the TargetID, Signal and Detection columns will be imported, the remaining columns will be ignored. This means that the annotations are not imported. The Signal is used as the expression measure.

Download a small example sample file here:

<http://www.clcbio.com/madata/IlluminaBeadStudioWithAnnotations.txt>

K.3.4 Illumina expression data, multiple samples in one file

This file format has too much information to show it inline in the text. You can download a small example sample file here:

<http://www.clcbio.com/madata/IlluminaBeadStudioMultipleSamples.txt>

This file contains data for 18 samples. Each sample has an expression value (the value in the AVG_Signal column), a detection p-value, a bead standard deviation and an average bead number column. The workbench recognizes the 18 samples and their columns.

K.3.5 Illumina annotation files

The Workbench supports import of two types of Illumina BeadChip annotation files. These are either comma-separated or tab-delimited .txt files. They can be used to annotate experiments as shown in section 20.1.4.

This file format has too much information to show it inline in the text.

Download a small example annotation file of the first type here:

<http://www.clcbio.com/madata/IlluminaBeadChipAnnotation.txt>

and the second type here:

<http://www.clcbio.com/madata/IlluminaBeadChipAnnotationV2.txt>

K.4 Gene ontology annotation files

The Gene ontology web site provides annotation files for a variety of species which can all be downloaded and imported into the *CLC Main Workbench*. This can be used to annotate experiments as shown in section 20.1.4. See the complete list including download links at <http://www.geneontology.org/GO.current.annotations.shtml>.

This is an easy way to annotate your experiment with GO categories.

K.5 Generic expression and annotation data file formats

If you have your expression or annotation data in e.g. Excel and can export the data as a txt file, or if you are able to do some scripting or other manipulations to format your data files, you will be able to import them into the *CLC Main Workbench* as a 'generic' expression or annotation data file. There are a few simple requirements that need to be fulfilled to do this as described below.

K.5.1 Generic expression data table format

The *CLC Main Workbench* will import a tab, semicolon or comma-separated .txt or .csv file as expression array samples if the following requirements are met:

1. the first non-empty line of the file contains text. All entries, except the first, will be used as sample names
2. the following (non-empty) lines contain the same number of entries as the first non-empty line. The requirements to these are that the first entry should be a string (this will be used as the feature ID) and the remaining entries should contain numbers (which will be used as expression values – one per sample). Empty entries are not allowed, but NaN values are allowed.
3. the file contains at least two samples.

An example of this format is shown below:

```
FeatureID;sample1;sample2;sample3
gene1;200;300;23
gene2;210;30;238
gene3;230;50;23
gene4;50;100;235
gene5;200;300;23
gene6;210;30;238
gene7;230;50;23
gene8;50;100;235
```

This will be imported as three samples with eight genes in each sample.

Download a this example as a file here:

<http://www.clcbio.com/madata/CustomExpressionData.txt>

K.5.2 Generic annotation file for expression data format

The *CLC Main Workbench* will import a tab, semicolon or comma-separated .txt or .csv file as an annotation file if the following is met:

1. It has a line which can serve as a valid header line. In order to do this, the line should have a number of headers where at least two are among the valid column headers in the **Column header** column below.
2. It contains one of the PROBE_ID headers (that is: 'Probe Set ID', 'Feature ID', 'ProbeID' or 'Probe_Id').

The importer will import an annotation table with a column for each of the valid column headers (those in the **Column header** column below). Columns with invalid headers will be ignored.

Note that some column headers are alternatives so that only one of the alternative columns headers should be used.

When adding annotations to an experiment, you can specify the column in your annotation file containing the relevant identifiers. These identifiers are matched to the feature ids already present in your experiment. When a match is found, the annotation is added to that entry in the experiment. In other words, at least one column in your annotation file must contain identifiers matching the feature identifiers in the experiment, for those annotations to be applied.

A simple example of an annotation file is shown here:

```
"Probe Set ID","Gene Symbol","Gene Ontology Biological Process"
"1367452_at","Sumo2","0006464 // protein modification process // not recorded"
"1367453_at","Cdc37","0051726 // regulation of cell cycle // not recorded"
"1367454_at","Copb2","0006810 // transport // /// 0016044 // membrane organization // "
```

Download this example plus a more elaborate one here:

<http://www.clcbio.com/madata/SimpleCustomAnnotation.csv>

<http://www.clcbio.com/madata/FullCustomAnnotation.csv>

To meet requirements imposed by special functionalities in the workbench, there are a number of further restrictions on the contents in the entries of the columns:

Download sequence functionality In the experiment table, you can click a button to download sequence. This uses the contents of the PUBLIC_ID column, so this column must be present for the action to work and should contain the NCBI accession number.

Annotation tests The annotation tests can make use of several entries in a column as long as a certain format is used. The tests assume that entries are separated by /// and it interprets all that appears before // as the actual entry and all that appears after // within an entry as comments. Example:

```
/// 0000001 // comment1 /// 0000008 // comment2 /// 0003746 // comment3
```

The annotation tests will interpret this as three entries (0000001, 0000008, and 0003746) with the according comments.

The most common column headers are summarized below:

Column header in imported file (alternatives separated by commas)	Label in experiment table	Description (tool tip)
Probe Set ID, Feature ID, ProbelD, Probe_Id, transcript_cluster_id	Feature ID	Probe identifier tag
Representative Public ID, Public identifier tag, GenbankAccession	Public identifier tag	Representative public ID
Gene Symbol, GeneSymbol	Gene symbol	Gene symbol
Gene Ontology Biological Process, Ontology_Process, GO_biological_process	GO biological process	Gene Ontology biological process
Gene Ontology Cellular Component, Ontology_Component, GO_cellular_component	GO cellular component	Gene Ontology cellular component
Gene Ontology Molecular Function, Ontology_Function, GO_molecular_function	GO molecular function	Gene Ontology molecular function
Pathway	Pathway	Pathway

The full list of possible column headers:

Column header in imported file (alternatives separated by commas)	Label in experiment table	Description (tool tip)
Species Scientific Name, Species Name, Species	Species name	Scientific species name
GeneChip Array	Gene chip array	Gene Chip Array name
Annotation Date	Annotation date	Date of annotation
Sequence Type	Sequence type	Type of sequence
Sequence Source	Sequence source	Source from which sequence was obtained
Transcript ID(Array Design), Transcript	Transcript ID	Transcript identifier tag
Target Description	Target description	Target description
Archival UniGene Cluster	Archival UniGene cluster	Archival UniGene cluster
UniGene ID, UniGeneID, Unigene_ID, unigene	UniGene ID	UniGene identifier tag
Genome Version	Genome version	Version of genome on which annotation is based
Alignments	Alignments	Alignments
Gene Title	Gene title	Gene title
geng_assignments	Gene assignments	Gene assignments
Chromosomal Location	Chromosomal location	Chromosomal location
UniGene Cluster Type	UniGene cluster type	UniGene cluster type
Ensembl Ensembl	Ensembl	
Entrez Gene, EntrezGeneID, Entrez_Gene_ID	Entrez gene	Entrez gene
SwissProt	SwissProt	SwissProt
EC	EC	EC
OMIM	OMIM	Online Mendelian Inheritance in Man
RefSeq Protein ID	RefSeq protein ID	RefSeq protein identifier tag
RefSeq Transcript ID	RefSeq transcript ID	RefSeq transcript identifier tag
FlyBase	FlyBase	FlyBase
AGI	AGI	AGI
WormBase	WormBase	WormBase
MGI Name	MGI name	MGI name
RGD Name	RGD name	RGD name
SGD accession number	SGD accession number	SGD accession number
InterPro	InterPro	InterPro
Trans Membrane	Trans membrane	Trans membrane
QTL	QTL	QTL
Annotation Description	Annotation description	Annotation description
Annotation Transcript Cluster	Annotation transcript cluster	Annotation transcript cluster
Transcript Assignments	Transcript assignments	Transcript assignments
mma_assignments	mRNA assignments	mRNA assignments
Annotation Notes	Annotation notes	Annotation notes
GO, Ontology	Go annotations	Go annotations
Cytoband	Cytoband	Cytoband
PrimaryAccession	Primary accession	Primary accession
RefSeqAccession	RefSeq accession	RefSeq accession
GeneName	Gene name	Gene name
TIGRID	TIGR id	TIGR id
Description	Description	Description
GenomicCoordinates	Genomic coordinates	Genomic coordinates
Search_key	Search key	Search key
Target	Target	Target
Gid, GI	Genbank identifier	Genbank identifier
Accession	GenBank accession	GenBank accession
Symbol	Gene symbol	Gene symbol
Probe_Type	Probe type	Probe type
crosshyb_type	Crosshyb type	Crosshyb type
category	category	category
Start, Probe_Start	Start	Start
Stop	Stop	Stop
Definition	Definition	Definition
Synonym, Synonyms	Synonym	Synonym
Source	Source	Source
Source_Reference_ID	Source reference id	Source reference id
RefSeq_ID	Reference sequence id	Reference sequence id
ILMN_Gene	Illumina Gene	Illumina Gene
Protein_Product	Protein product	Protein product
protein_domains	Protein domains	Protein domains
Array_Address_Id	Array adress id	Array adress id
Probe_Sequence	Sequence	Sequence
seqname	Seqname	Seqname
Chromosome	Chromosome	Chromosome
strand	Strand	Strand
Probe_Chr_Orientation	Probe chr orientation	Probe chr orientation
Probe_Coordinates	Probe coordinates	Probe coordinates
Obsolete_Probe_Id	Obsolete probe id	Obsolete probe id

Appendix L

Custom codon frequency tables

You can edit the list of codon frequency tables used by *CLC Main Workbench*.

Note! Please be aware that this process needs to be handled carefully, otherwise you may have to re-install the Workbench to get it to work.

In the Workbench installation folder under `res`, there is a folder named `codonfreq`. This folder contains all the codon frequency tables organized into subfolders in a hierarchy. In order to change the tables, you simply add, delete or rename folders and the files in the folders. If you wish to add new tables, please use the existing ones as template.

Restart the Workbench to have the changes take effect.

Please note that when updating the Workbench to a new version, this information is not preserved. This means that you should keep this information in a separate place as back-up. (The ability to change the tables is mainly aimed at centrally deployed installations of the Workbench).
